Although it is true that milk of lime is used in a small number of continuously operated water-softening machines of considerable size, the agitation factor is more particularly emphasized in such apparatus than would perhaps be feasible in larger plants. Without adequate mixing of the raw water and the milk of lime there is a marked loss in softening efficiency on the part of concentrated suspensions of lime, owing to the fact that the suspended particles of calcium oxide become coated over with the precipitating carbonate of lime and hydrate of magnesium, and thereby become inactive. With vigorous agitation this vitiating factor—the inactivity of a part of the lime suspensions—is greatly diminished, but doubtless it is still to be considered as important in proportion to the amount of suspended calcium oxide which the milk of lime contains.

From the evidence available it appears to be clear that limewater possesses distinct advantages over milk of lime in continuously operated water-softening plants for two reasons—first, because of the relative ease with which accurate and uniform application of this chemical may be maintained when it is applied in solution, and, second, because the softening efficiency of limewater is relatively higher. This second consideration involves questions of cost, which must be considered.

In a system of water softening operated on the continuous plan the device in which limewater is prepared is an important feature. In practice limewater is generally produced by diverting a portion of the raw water to the bottom of a tank or reservoir, sometimes known as the lime saturator, where it meets a continuous flow of cream of lime in slight excess of the quantity necessary to soften the raw water and to produce a saturated limewater. Thorough mixing of the cream of lime and the raw water is obtained by means of a stirring device situated at the bottom of the lime saturator. The raw water, softened to the fullest extent possible by treatment with cream of lime alone, becomes a saturated solution of lime. In order to obtain limewater which shall be practically free from undissolved lime and the precipitated salts of lime and magnesium the saturator is made sufficiently deep so that, as the water passes upward to the outlet at the top of the tank, the suspended matter will largely subside.

Preparation of Soda-Ash Solution.—Available evidence indicates that a 20 per cent. solution of soda ash in hot water should be used. Such a solution has a specific gravity of 1.23. A solution of approximately this composition is made by dissolving 20 pounds of soda ash in 100 pounds of water.

Limitations in Water Softening.—When once raw water, charged with carbon dioxide, has in its course over or through the earth become impregnated with calcium and magnesium there is no practical process applicable to municipal use which can restore the water to its pristine condition.. The reactions and the resulting precipitation will vary in completeness with conditions of temperature, mixing, and sedimentation. Furthermore, the precipitates formed are not wholly insoluble. In a water softened under ideal conditions there may remain in solution 5.2 parts per million of calcium and 3.4 parts per million of magnesium, together with equivalent amounts of negative radicles, representing an alkalinity of nearly 30 parts per million. These figures may be increased by the presence of other substances, so that it is apparently certain that a water once hard can not be softened in a practical plant to less than 34 to 37 parts of alkalinity per million.

With regard to the permanent hardness, it is not generally thought economical or advisable to remove all of the incrustants. As soda ash, which is used for the removal of these constituents, constitutes one of the chief items of expense in softening a selenitic water, its use should be restricted to the lowest limit commensurate with the benefits to be derived therefrom.

Factors Influencing the Speed of Softening Reactions.—The process of softening water requires considerable time for its completion. Chief among the factors that influence the rapidity with which the chemical reactions involved in the softening process may take place are the temperature of the water, the thoroughness of the agitation to which the water is subjected following the addition of the softening chemicals, and the maintenance in suspension of the precipitating salts during the period allowed for the reactions to take place.

It is a well-known and accepted fact that the majority of chemical reactions take place with relatively more rapidity as the temperature is increased. Those chemical reactions which are involved in water softening belong distinctly to this class. Cold weather during softening retards the process to such an extent that considerably more time is required for the completion than when the water is at a higher temperature; in extremely cold weather the maximum softening effect is often not obtained.

Even when the amounts of chemicals theoretically necessary for complete softening are applied to a given water, a satisfactory removal of the dissolved calcium and magnesium salts will not be obtained without thorough agitation. The importance of agitation in softening water has long been recognized, the means for effecting this end constituting an important feature in the design of the majority of proprietary water-softening machines.

It is a well-known fact that the presence in suspension of the precipitate previously formed or of that formed in the initial stages of the reaction generally assists materially the completion of the process, its success depending on the removal of dissolved substances by the formation of a precipitate as the result of chemical reactions. In water softening this matter is of particular moment, owing in large measure to the fact that the chemical changes involved are taking place in solutions of a high degree of dilution. The importance of the presence of the suspended precipitates throughout the course of the softening reaction has been recognized for many years, and many water-softening machines have been designed with the view of retaining these precipitates.

Available information indicates clearly that at the beginning of the softening process it is highly advantageous to apply the entire amount of lime required to the major portion but not to the total amount of the raw water to be softened. Mention has already been made of the fact that the maintenance in suspension of the forming precipitates materially accelerates the softening reactions. By overdosing a major portion of the water to be softened, the initial softening reactions are greatly accelerated. The action is particularly marked in the precipitation of the magnesium, which is much more rapidly and completely removed under the conditions outlined above than would otherwise be the case. Further, the indications are

strong that by splitting the flow of water to the reaction chamber, overtreating with lime the major portion at the inlet end of the reaction chamber, and, some time after the application of the soda ash, introducing the minor portion of the raw water, the undesirable factor of residual causticity, true of all water-softening processes, would in a large measure be overcome.

In general, therefore, it may be said that the concentrated action of the total amount of lime on the major portion but not on the total amount of water serves to speed up and to render possible a more complete lime reaction, not only as relates to the removal of magnesium but also to the removal of the calcium.

Elimination of Residual Causticity.—In all processes of softening hard water in which lime or caustic soda are used as softening agents, there is a possibility that the softened product will at times contain an excess of free caustic alkali, owing to the frequent changes in the character of the raw water, or to carelessness or accident in the operation of the plant, or to the method of application of the softening chemicals to the raw water. Another condition instrumental in the production of a caustic effluent is the retarding effect caused by low temperature on the rapidity and completeness of the softening reaction. In systems of water softening where the period allowed for the softening reactions to take place is comparatively short, particularly where such plants are designed to furnish water for drinking, rigid precautions are demanded to overcome the occasional inevitable residual causticity. In some plants the matter is controlled by installing carbonating devices for the purpose of subjecting the softened water to the action of carbon dioxide. If properly distributed in adequate amounts through a water possessing causticity, this gas is effective in overcoming this inadmissible condition.

This process is known as "carbonating," the principle involved being the same in all devices designed to accomplish this end. The features essential to successful carbonating are the uniform rate of application of the gas, and the thoroughness with which it is disseminated through the water. Although the process is without doubt practicable for small water-softening plants, its use in large plants would probably entail too great an expense to justify its installation. Further, aside from the cost, which perhaps might be reduced, it appears that the application of the gas to large volumes of water would cause great uncertainties in this feature of the plant, which must be under perfect control at all times.

Causticity that the raw water can neutralize is obviously equal to the amount of caustic lime (or caustic soda) required to soften the water. As a substitute for the carbonating devices in use in small water-softening plants, the application to the softened water of a small percentage of raw water may be practiced. It is apparent that the percentage of raw water required for each part of free causticity which may remain in the softened water will be one hundred times the reciprocal of the number of parts of lime (CaO), required to soften the water. In other words, all unchanged caustic alkalinity which the softened water may contain will be neutralized by the addition of a small percentage of raw water, the caustic neutralizing power of which is at a maximum.

Sedimentation of Softened Water Prior to Filtration.—Where river waters are to be softened, filtration usually follows the softening process. The necessity for the sedimentation of the softened water after the reaction period and prior to its filtration refers to the removal of an economical percentage of the precipitated salts of lime and magnesium, together with the suspended mud, silt, and clay carried by the water at flood seasons. It is clear that it would not be practicable or economical to apply to filters the softened water as it leaves the reaction chamber. As the precipitating salts are purposely held in suspension during the reaction period, the major portion of them passes out with the water as it leaves this chamber. The volume of this precipitate will be so great as probably to preclude the direct application to the filter of the water as it leaves the reaction chamber. Furthermore, at times when the river water carries high amounts of sediment, economy in filter operation demands that a period of sedimentation be allowed to intervene before such water is applied to the filter in order that a substantial removal of the mud, silt, and clay may take place in the settling basins.

For still other reasons it appears advisable to provide for several hours' subsidence as a means for compensating irregularities in the operation of a softening plant, namely, to guard against incomplete softening in the reaction period; to overcome uncertain factors introduced by winter weather, producing retardation of the softening action; to avoid the undesirable effect produced by possible after-reactions, which cause deposition of slow-forming precipitates on valves, boiler-water condensers, and the like, and to remove the esthetic objection introduced by the presence in the water, as delivered to the consumer, of small particles of precipitated lime and magnesium compounds.

RATING REFRIGERATING MACHINES.

In this country there are two generally accepted units for rating a refrigerating machine. These are commonly called the ice-melting or refrigerating capacity and the ice-making capacity. Both are expressed in tons of 2,000 lb. per day of 24 hour. When a machine is rated at one ton ice-melting or refrigerating capacity, it would mean that under an assumed range of operating temperature it would remove from the refrigerator the number of heat units equivalent to that required to melt one ton of ice at 32 deg. F. into water at 32 deg. F. The latent heat of ice has been variously taken as 142, 143, 143.7 and 144 B.t.u., but 144 B.t.u. is now the figure generally accepted. Then

$$2{,}000 \times 144 = 288{,}000 \ B.t.u.$$

is the equivalent of a ton of refrigeration per day of 24 hr. This would give 12,000 B.t.u. per ton per hour and 200 B.t.u. per ton per minute, all convenient figures to work with. The machine is supposed to work between a condenser temperature of 90 deg F., and a temperature of zero in the expansion coils.

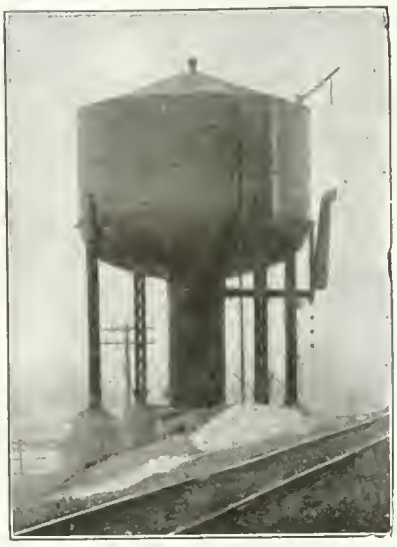
The ice-making capacity is a measure of the actual weight of ice made by a machine, designed for the purpose, in tons per 24 hr. For a machine not designed for ice making this unit would appear of little value, but for the sake of comparison it is approximately six-tenths the ice-melting or refrigerating capacity.

The Board of Railway Commissioners for Canada has issued to the railways a circular calling attention to the advisability of warning employees about the absolute necessity of keeping away from all electric light or power lines, and also to the advisability of becoming familiar with the recently revised rules for "Resuscitation from Apparent Death from Electric Shock."

NEW INDUSTRY FOR CANADA.

The Chicago Bridge and Iron Works, which has developed a prominent type of steel water tank for municipal, factory and railroad service, has built and is now operating a new plant at **Bridgeburg, Ontario.** This company began twenty years ago to construct for small towns and cities the hemispherical bottom type of tank, and since then has built a great number of tanks in every province in Canada and in every state in the United States.

About ten years ago Mr. George T. Horton, now president of the Chicago Bridge and Iron Works, designed and patented the elliptical bottom tank intended at first only for locomotive service. This tank, as shown by the cut above, has a large diameter and shallow depth, thus giving, as nearly as possible, the absolutely uniform pressure that is so desirable for all kinds of water service. Its special feature is the large steel riser pipe riveted directly to the tank bottom. This construction eliminates the leaky expansion joint and wooden frost casing, common to all other types of tank, and makes an all-steel structure which will last indefinitely. The large riser pipe is built from three to six feet in diameter, depending upon the climate. The success of the design is well illustrated by the municipal tank at Moose Jaw, shown herewith, which has never been put out of service by the coldest weather.



Grand Trunk Pacific Railway; Capacity, 50,000 Gallons; Height, 20 Feet to Bottom.

The tank bottom is practically flat where the riser is attached. It is, therefore, flexible and is in itself an ideal expansion joint, as is testified by the large number of high tanks of this design now in successful service. One in particular, a 200,000 gallon tank, 175 feet to the bottom, shows how well the expansion is taken care of. This elliptical bottom is now widely used for municipal and sprinkler as well as for locomotive service.

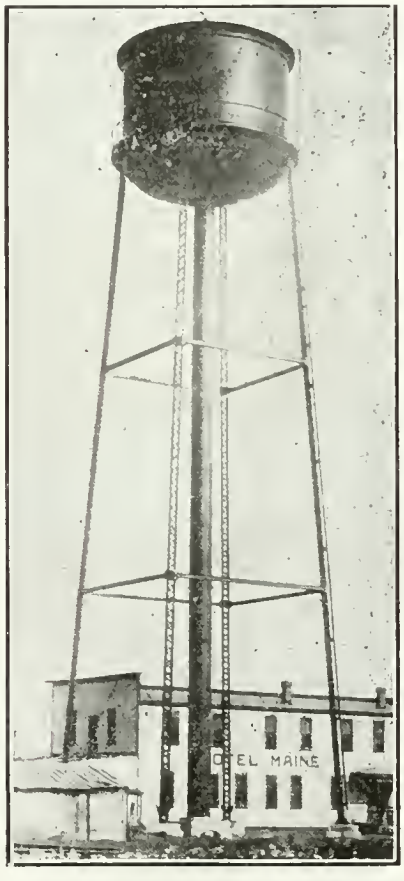
The large riser, besides doing away with wooden frost casing and expansion joints, serves as a settling basin. The inlet and outlet pipes extend up into the large riser several feet so as to be above any possible accumulation of sediment. A washout valve, operated from the outside, is installed at the bottom, so the tank can be cleaned without emptying or interrupting its service.

The self-cleaning feature of these tanks proved so important that Mr. Horton went a step farther. He designed and patented for railroads using extremely muddy water a conical bottomed tank with a large riser. This tank differs from the elliptical type only in that the bottom makes an angle of not less than forty-five degrees with the vertical so that the sediment has no chance to stop on its way to the settling basin.

How well these tanks are liked by the railroads is shown by the fact that they are in use on 85 railroads in numbers from 1 to 150 tanks per railroad.

Three years ago the Chicago Bridge and Iron Works' all-steel locomotive ser-

Edmonton, Alberta; Capacity, 75,000 Gallons; Height, 81 Feet to Top.



Capacity, 100,000 Gallons; Height, 111 Feet to Top; Moose Jaw, Saskatchewan.

Standard Elliptical Bottom Design; Capacity, 200,000 Gallons; Height, 175 Feet to Bottom.

vice tank was introduced on the Canadian railways when the Grand Trunk Pacific built a tank for experimental purposes at Scott, Sask. This tank proved so satisfactory that steel tanks were adopted as the standard for the entire system. Twenty-six tanks of the design shown herewith are now being installed at different points west of Winnipeg by the Chicago Bridge and Iron Works.

The elliptical or conical bottom tanks when installed at terminal points, or points where much water is used, do not require any heating even in Canada. Where but little water is used and steam is available a steam jet introduced into the tank near the bottom is a very satisfactory method for preventing an undue amount of ice.

Two years ago, when the Chicago Bridge and Iron Works tank was adopted as a standard on the Transcontinental Railway between Superior Junction and Cochrane, Ontario, the question of heating isolated tanks where no steam supply was available came up for consideration. Mr. Horton then suggested the method described below, which the Government engineers later adopted, and which has since been adopted by other railroads and other tank manufacturers.

The method used is very simple and consists of raising the bottom of the large riser a few feet, and installing a stove in the small room provided. The stove pipe extends up through the centre of the tank and out through the roof. The inside of the large riser at the bottom is lined with brick so as to prevent the heat from radiating.

The company has in operation, besides its original plant at Chicago, and its new shop at **Bridgeburg,** a plant at Greenville, Pa., in the Pittsburg district.

The mines branch of the Canadian Department of Mines has installed at Ottawa a modern laboratory for the purpose of experimental concentration and metallurgical tests with Canadian ores and minerals. The laboratory appears to be already well-equipped with both standard size machinery and small-scale apparatus, and an experimental roasting and sintering plant is to be added shortly. The plant will be operated free of all charges, including assays necessary for test purposes, on Canadian ores and reports of tests will be incorporated in the publications of the Mines Branch. Under ordinary conditions tests will be made by the Mines Branch officials, but arrangements may be made whereby engineers or other competent persons may supervise their own experiments.

During the month of May last the railways of the United States, according to the Bureau of Railway Economics, received for their services to the public an average of $8,230,000 a day; it cost to run their trains and for other expenses of operation, $5,920,000 a day; their taxes were $341,500 a day; their operating income, $1,972,322 a day for the 220,897 miles of line reporting, or at the rate of $8.93 for each mile of line for each day. Thus for every six dollars of their earnings which remained available for rentals, interest on bonds, appropriations for betterments, improvements and new construction, and for dividends, the railways had to pay more than one dollar in taxes. All of these amounts are substantially greater than the similar returns for May, 1912. They are from the summary of the earnings and expenses compiled by the Bureau of Railway Economics from the monthly reports of the steam railways of the United States to the Interstate Commerce Commission. They include over 95 per cent. of the mileage and earnings of all the railways of the country.

THE FINANCING OF MUNICIPAL WORKS.

Comparison of Canadian, British and South African Methods.

By R. O. Wynne-Roberts,
M.Inst.C.E., M.Can.Soc.C.E., Consulting Engineer,
Regina, Sask.

The subject of loans required for the execution of municipal works, is one with which Canadian municipalities have been openly confronted with in the course of the present season. A few observations bearing with special significance upon Western Canadian municipalities, may be considered opportune, they being chosen. Firstly, because much attention has been directed to the amount of money required by them; secondly, because the conditions are unique in the history of British municipalities, and thirdly, because the precedure observed in relation to obtaining money for new works is somewhat different to that obtaining in other parts of the empire.

In England the growth of towns has been steady and practically uniform, during the last fifty years. Some towns have grown much quicker than others, but the average increase of urban population was about 15 per cent. between the years 1891 and 1901, and about 11 per cent. in the next decennium.

Some boroughs round London had grown about 26 per cent. in the years 1901-1911; this was due to immigration from the central parts to the suburbs owing to improved transportation facilities.

The following probably represents the largest increases in England and Wales during the last census period.

	Population.	Increase per cent.
Croydon	169,500	26.6
Rhondda	152,780	34.3
Swansea	114,663	21.3
Huddersfield	107,821	13.4
Cardiff	182,259	10.9
Sheffield	454,632	11.1
Belfast, Ireland	385,000	10.4

When Sir Robert Rawlinson was commissioned by the government to investigate the sanitary condition of Lancashire towns, in the forties or thereabouts, public health works were most inadequate and unsatisfactory. Sir Robert initiated great schemes to provide work for masses of men who were out of employment owing to the depression which then prevailed.

From that time to the present, English municipal authorities have gradually carried out such works. The growth of the population was steady, very few towns have had any exceptional development, and there has been no difficulty in undertaking schemes which would be ample for a generation ahead. Water supplies, sewerage schemes, street railways, electric light, gasworks, and other municipal works have therefore been provided without imposing an undue burden on the ratepayers. The only public work of importance which was difficult to carry out with a degree of assurance of success was that of the purification of sewage.

In South Africa, the conditions are different, for apart from Capetown district, Port Elizabeth, East London, Durban, Pretoria and Johannesburg, the population of the British and Dutch element has not grown to any extraordinary extent. The above towns during the ten years ending 1911 have grown considerably, but not in anything like the same manner as Western Canadian cities. Johannesburg is about 30

years old, but the other South African cities are much older and all have had time to carry out many municipal works, but there is much left to be done.

With regard to Canadian expansion, it may be instructive to analyse and compare the census returns for the 1911 decenium. The increase in population in Canada was 32 per cent. as compared with 11 per cent. in England and Wales. The province of Saskatchewan had increased 439.48 per cent.; Alberta, 413.08 per cent.; British Columbia, 119.68 per cent.; Manitoba, 78.52 per cent.; Ontario, 15.58 per cent.; and Quebec, 21.46 per cent.

The urban population in Canada had grown 62.25 per cent. as compared with 11 per cent. in England and Wales.

If we analyse the returns still further we find that the increase in a few of the cities were as follows:—Regina, 1243.40 per cent.; Moose Jaw, 787.23 per cent.; Edmonton, 848.21 per cent.; Vancouver, 51.35 per cent.; Fort William, 354.11 per cent.; Toronto, 80.99 per cent.; Saskatoon, 105.23 per cent.; Calgary, 893.72 per cent.; Medicine Hat, 257.20 per cent.; Winnipeg, 221.29 per cent.; Ottawa, 45.27 per cent.; Montreal, 75.73 per cent.

It may be interesting to know that Toronto and Belfast have about the same population but the rate of increase was as 8 is to 1. Montreal and Sheffield are somewhat similar in the number of inhabitants, yet the growth of Montreal was nearly seven times as great as in Sheffield. Winnipeg in 1911 was about three-fourths the size of Cardiff, but the expansion of the former was about 21 times as much as the latter.

Unfortunately, comparative figures are not at present available to contrast the other Canadian cities mentioned, but there is no doubt that their growth has been enormous as compared with English standards. It is palpable that in the West, the development of villages into towns will show an abnormal percentage of increase, but even if such cases are excluded, the expansion was far in excess of what ordinarily occurs in other countries.

The influx of people into Western Canada during the last five years was even greater than in the decenium 1901-1911. For instance, the writer when investigating the question of water supply of Regina, found that the annual increment for five years ending 1912 was about 36 per cent. compound. It is, of course, possible that this rate of increase has been equalled or even exceeded in other cities.

The extension of railways, the great development of the agricultural industry and the immigration of people, demand the creation of new towns and villages to provide for the commercial and social requirements of the inhabitants generally.

The enormous growth of the existing towns and the ever-increasing number of new villages, some of which develop very quickly, give rise to sanitary works, better means of locomotion, more efficient lighting, cheap power, and the many other civic requirements of modern times.

It will be acknowledged that the best policy and the only efficient administration for municipal authorities to undertake, is to carry out the necessary public works as the towns grow, and not to allow the works to accumulate in such a way as to be difficult to be overtaken. It is far cheaper and more satisfactory to carry out sanitary works in advance of the actual requirements, rather than to neglect keeping abreast of the times, and wait until a disastrous epidemic of some disease has broken out, which will not only need eradicating, but also the execution of the essential precautionary works, after causing sufferings and losses which cannot be reckoned in dollars and cents.

The influx of people into Canada, therefore, imposes an important and difficult duty on the municipal authorities, which cannot be safely ignored. That the majority of the authorities are endeavoring, within the statutory limits of their borrowing powers, to meet the requirements is proved by the calls for capital.

While English municipalities have had fully fifty years to carry out such works, the Canadian cities and especially, the Western ones, are called upon to undertake the same in about ten years. The difficulty is enhanced by the exceptional growth, for engineers find it almost impossible to estimate the future with the same confidence as they can in other parts of the world.

This difficulty is not inherent to city works, for banking corporations have frequently erected buildings which were soon found to be inadequate; railway companies have built railways and structures only to find that it was necessary to enlarge the same almost before completion; governments are guilty of similar delinquency, and business men who erected what others called "white elephants," have had to face similar conditions and exigencies.

Such, then, is the almost universal development of municipal enterprises in Canada. It is small wonder that criticisms have been levelled at civic authorities, both by investors who are not thoroughly familiar with Canadian expansion, and by people who are disappointed to find that public utilities are not developed as in England. The problem is to find the money needed. The financial aspect of this question is probably more interesting than the incomplete description of the conditions which now prevail.

The monetary requirements of a Canadian city is controlled by the total assessable value of the properties, for the power to borrow is usually limited to twenty per cent. of such value.

The next question to be dealt with will be the procedure observed when seeking loans for new works.

In England and Wales, there are the borough councils, which consist of the mayor, aldermen and councillors. The mayor is elected from among the aldermen and councillors for one year, sometimes he is elected from outside the council. The aldermen are elected from among the councillors for a term of six years, and the councillors are elected by the ratepayers for a term of three years. The urban district councils consist of the chairman and councillors.

There is usually a plethora of candidates for these honorary offices, and in the majority of towns the members have held office for many years. In the boroughs the aldermen add more permanency to the membership and policy. There is much to be said in favor of aldermen and also against the institution. Aldermen act like a ballast to a ship, so long as they are sensible and progressive, but there is a tendency sometimes, for aldermen to adhere to obsolete ideas and ignore up-to-date requirements on the plea of economy.

When any English municipal authority has decided to carry out any new scheme, the engineer prepares plans, estimates and specifications, and when these have received the approval of the council, the clerk is authorized to forward a copy of the same with an application to borrow the necessary amount of money, to the Local Government Board, which is a large government department controlling almost everything associated with civic affairs.

In due time an engineering inspector holds an official enquiry in the particular town, when the clerk, mayor, aldermen and engineer place full particulars of the town's indebtedness, population, assessment, borrowing powers, necessity for the works involved, and so on. When they have presented the case the inspector calls for evidence in opposition—if any—and at the close of the enquiry he proceeds to the site to make a personal inspection. The inspector reports to the board and that body sanctions or disapproves of the schemes,

or it may consider it necessary that a poll of the ratepayers should be taken, before giving any opinion or decision.

If the scheme receives the sanction of the Local Government Board, and it has authorized the period of repayment, the council is at liberty to approach the public works loan commissioner, or any other financial concern for offers or terms.

The Local Government Board, or the L.G.B., as it is known among the officials, is a restraining factor in the control of expenditure of public funds. The borrowing powers of the councils is usually limited to twice the rateable value, which in England is based upon the rack-rent of the properties, and not on the actual values.

The councils can undertake any new work, after its authorization by the Local Government Board at any time of the year, and float so much of the loan as is necessary or deemed expedient at the most propitious moment.

The Local Government Board is a slow moving department, often much criticised, but it is acknowledged to be an excellent organization, free from political influence, and possesses great powers to force recalitrant councils to execute any necessary works. Such powers, however, are very rarely exercised. It can, nevertheless, restrain too ambitious councils in their expenditure of moneys on doubtful schemes, or when their borrowing powers are nearly exhausted. It is somewhat conservative in its methods and adaptation to new development; bacteriological treatment of sewage and reinforced concrete structures, are instances of new methods to which it was for some time not prepared to give its sanction, except for short period loans. It will not consent to radical changes without ample proofs that they are essential in the interest of the public.

Under the English method the town authorities can take the fullest advantage of the financial fluctuations and thus ensure obtaining money on the most economical terms, which must be repaid in the period prescribed by the Local Government Board.

In South Africa, the procedure is different. The council having decided to undertake certain works for which preliminary plans, specifications and estimates have been prepared, calls a ratepayers' meeting and submits the proposals. If the ratepayers present are unanimous in favor, then the works are authorized, but if a certain number rise and demand a poll, then a plebiscite of the ratepayers is taken and the schemes are either agreed to or rejected. No formidable by-laws are necessary. If the schemes are approved by the ratepayers, the council can go on the money market at any time and thus take full advantage of the financial situation. Municipal schemes are decided upon at any time, and it is rare that any of them are suspended, altered, or turned down by new members because the policy is sufficiently established by the constitution of the council. Occasionally a scheme becomes the matter of an election contest, and the decision affords a guidance to the council in that particular case.

In Canada the procedure is different to both the foregoing examples.

The council usually decides what shall be undertaken in any year, so far as is possible. Of course, some schemes require more than one year for their execution, but the council of one year does not often settle what may be done in the next year, because the members are elected for two years and it is quite possible under such conditions to find a large proportion of new members elected at any time. Aldermen are usually busy men, engaged in businesses which calls for their close attention, whilst civic administration also demands a great amount of time which many aldermen can ill-afford. The result is found in the appointment of city commissioners, or the election of controllers, who devote their whole time to civic business, and thus relieve the aldermen of some of the administration.

The new council takes office in January each year, and some time is necessary to get the organization into working order. The aldermen call for reports, plans, etc., of works to be carried out during the year, some of which have sometimes, been considered in the previous year, in which case, if the new council acquiesces, there is a certain ecenomy of time. In due course the council decides to undertake many schemes, by-laws have to be prepared and read twice at the meetings. Then the by-laws, which recite in full various particulars and different legal phraseology, are published. The poll of the ratepayers is necessary and this is taken in ordinary course, and on the result depends whether and which schemes are to be carried out.

When the routine has been carefully observed, then the by-laws are read a third time, and advertisements are issued for bids, the most acceptable of which are selected.

All this means time, if any preliminary consideration by the council of the preceding year has taken place it permits of more expedition, provided the present council agree to such proposals.

The above procedure has to be strictly observed, otherwise the work is null and void, and the correct formalities have to be gone through and more time absorbed. As this routine must be followed by every council at about the same time, it is evident that the work is complete from March to May each year.

In Saskatchewan, the authority of the commissioner of public health is necessary before any schemes relating to public health can be submitted to the ratepayers for their approval.

In Canada, therefore, the town authorities are on the market for money about the same time, with the result that the aggregate amount appears enormous. The occasion may, however, be most inopportune, owing to financial stringency, caused by political events, abnormal industrial requirements, and perhaps by popular momentary wave of preference for securities of other countries or class. It is well known, that there is a fashion in investments as in other mundane matters, and this induces a fluctuation in the value of Canadian municipal loans, etc.

The almost simultaneous demand of many Canadian cities for money, is not to be commended. It does not usually occur in any other part of the world. It constitutes a flood of investments which cause financial indigestion and takes times to overcome.

There is a need for a greater continuity of municipal policy which can probably be attained by a longer period of election, say for three years instead of two as at present. Then fewer men will retire each year and councils will have a more established programme. If the present procedure is essential for the safeguarding of public interest, then it is a question whether the election should not be held at another time so as to permit the aldermen organizing their plans earlier. This, however, will not remove the disability due to the demand for money at practically the same time.

The character of the loan is a matter deserving of careful consideration. Instead of selling debentures required for various works in one class, they would possibly yield better average returns if those required for waterworks, electric works, street railways, and other reproductive works were disposed of individually. This is the usual practice in England and South Africa. Moreover, it is worthy of consideration whether ordinary debentures are as saleable as stock.

Many cities find it profitable to obtain funds by selling stocks of $500 and upwards.

Reverting again to the matter of procedure, it would appear that something more elastic on the one hand and more rigid on the other is necessary. This may seem paradoxical, but it is not so. The procedure should be sufficiently elastic to enable the councils framing their public works programme so as to permit them taking advantage of the financial fluctuations. It should also enable the councils to decide what works should be carried out and what money is required and come on the market at any time of the year, so that not too many of the Canadian authorities will do so simultaneously. It should be elastic enough to allow the councils to submit proposals to the ratepayers, at any time of the year, if such a procedure is really necessary. The ratepayers have elected their representatives and they might be given more freedom of action in this respect.

The procedure should also be rigid so as to protect the ratepayers and investors alike. One section of the ratepayers may have sufficient influence to force a scheme which might not be essential to the general public as another one might be. Some ambitious new aldermen may want a scheme delayed so that his may have a chance. The investor also wants safeguarding, for he is usually away from the place where the money is required. At present he has documentary evidence of the city officials supplemented in some cases by the government official. It would seem that the procedure could be made more rigid by adapting the English Local Government Board method, to suit Canadian conditions. To adopt the Local Government Board plan would no doubt be too drastic, and perhaps too great a restraint on the enterprising western Canadian councils. But to the British investor, (for most of the money comes from Great Britain), some independent and impartial investigation and sanction is desirable.

The Board of Railway Commissioners of Canada is reputed to give satisfaction to the public. The Public Utility Commissioners of Manitoba and Quebec are also said to fulfil their functions impartially and have done good work. Would it not be an advantage if similar organizations were instituted to facilitate and regulate municipal loan schemes? The fact that all municipal schemes were considered, investigated and sanctioned by such boards would doubtless have a great influence on the opinions of financiers, for it would be a satisfaction to them as well as to the ratepayers to know that all schemes have to be sanctioned or rejected by independent official authorities, who shall be absolutely free from political control. If such boards were constituted the town authorities would be able to prepare and submit any scheme at any time, and having got the necessary sanction of the board, with the period of repayment fixed, the councils could then arrange to secure the funds at the most opportune moment and on the most favorable terms. The present cumbersome procedure would then be unnecessary as there would be every safeguard in the interest of the ratepayers.

With the establishment of such boards, and a revision of the constitution of the town authorities, so as to secure a greater continuity of policy, Canadian authorities would be in a better position to obtain capital and to better arrange their programme of public works. Schemes could then be dealt with individually instead of collectively at any period of the year.

In conclusion it may be instructive to describe German municipal procedure. The city council consists of deputies elected by the ratepayers for three years; they appoint the Ober-burgermeister and a Vice-burgermeister at salaries for twelve years, and a number of stadräte or councillors, some of whom are salaried and correspond to our city commissioners. The burgermeisters and stadräte have a right to vote in council. When the council of deputies and stadräte presided over by the burgermeister has decided to embark on any scheme, the same is remitted to the burgermeisters and stadräte in charge of the branch controlling that particular work. The ober-burgermeister, vice-burgermeister and stadräte first settle all details in conference—called the magistrate collegium—and a report is presented to the council of deputies, when they finally decide the matter. The money is obtained either from an "operating fund" or by loan; but if it involves a large amount it ultimately means a loan. This is arranged with financial houses and the work proceeds. It is maintained that the ratepayers having elected their representatives it is left to them to use their judgment as to what is advisable to be done in the interest of the citizens. The government has certain powers of restraining municipal authorities, where it is felt that injudicious expenditures are incurred, otherwise the city authorities have complete independence in the administration of civic affairs.

ROCK SALT IN BRITISH COLUMBIA.

An extensive bed of rock salt has been discovered on the Skeena River, about 45 miles from Prince Rupert. Five holes have been drilled, about a mile apart, and salt has been struck in every case at depths varying from 50 to 250 feet. About eight tons of salt has been raised. The product is absolutely pure and of the best quality.

The Halifax Power Co. is planning to develop two sites on the Indian River, 18 miles west of Halifax. The upper station will include two units of 1,200 K.V.A. each. One operates on 90 ft. head from the Indian River watershed and the other on 160 ft. head from the North-East River watershed; the latter water is carried over to the Indian River by means of a long pipe line. The lower station will include two units of 1,200 K.V.A. operating on 90 ft. head; in this station the step-up transformers and high-tension gear will be placed. These developments will render 5,600 H.P. available in Halifax, which will be carried over a duplicate transmission line by two separate routes. Transmission will be at 33,000 volts. It is the intention of the company to sell this power for lighting and industrial requirements in Halifax. Plans are well under way for the upper development, one transmission line and receiving station, and it is expected that this portion of the work will be proceeded with immediately.

The exhibit of Canadian Allis-Chalmers, Limited, at the convention of the Canadian Association of Stationary Engineers held at Owen Sound, included a perfect working model of 36" size Squire's trap. Water was supplied to it by a small centrifugal pump driven by an electrical motor and a great deal of interest was taken in its operation.

Announcement is made by the B. F. Sturtevant Company, of Boston, that the plant which they have purchased at Galt, Ontario, is in such a condition that they can begin almost at once the manufacturing and assembling of their more important lines. Fans, blowers, planing mill exhausters, propeller fans, heating and ventilating apparatus, fuel economizers, mechanical draft, steam turbines, vertical engines, generating sets and stokers will be built for Canadian business and also for export to England, Australia and other countries. The manufacturing, engineering and sales will be handled by men trained by the Boston company. Arrangements have been made providing for growth up to ten acres of plant.

COAST TO COAST.

Montreal, Que.—The claims of ship owners, confirmed to a certain extent by records, that the level of the river and great lakes is being constantly lowered, principally by drainage operations, is about to be subjected to a practical test which should prove convincing to the most skeptical. According to information obtained to-day, the gauges between Port Arthur and Quebec, which are to be used in making the test, are now all in position by a special commission consisting of Prof. Haskell, of Cornell University, V. W. Forneret, chief engineer of the ship-channel and W. J. Stewart, chief hydrographer to the marine department. As the United States minister of war did not grant the application made by the Chicago drainage authorities last year for permission to increase the quantity of water they are entitled to take from Lake Michigan, the results of the tests are awaited with interest in shipping circles.

Victoria, B.C.—"The most important thing which the forestry convention did when it met at Winnipeg recently, was to pass a resolution urging upon the various provincial governments the importance of making provision for the teaching of forestry in the new universities."

That is the opinion of Mr. H. G. McMillan, the chief forester of the provincial government, who has just returned to the city after making an extensive visit of the forestry station in the interior, in company with Mr. O. W. Price, consulting forester to the government, who is here in connection with his engagement to assist in the establishment of the new department.

"What the future will demand in this province is forestry engineering and the university must provide the men and the methods. We have to develop trained forest rangers and make a study of forest engineering, for by the present look of things it appears inevitable that the logging of the future will be done by machinery. That I think was the most important thing the convention did, at all events so far as this province is concerned. There were two notable subjects discussed, namely, the extension of the civil service idea as applied to forestry and the encouragement of tree planting on the prairies. The prominence given to the last mentioned subject is perhaps best explained by stating that the convention took place in Winnipeg, where tree planting is a business.

"Since attending the convention I have been making a round of the interior stations, including Vernon, Cranbrook, Nelson, Kamloops and Vancouver and I must say that everything appears to be in good shape. The fire period is now upon us; the vegetation is extremely dry in places and the danger imminent. It will require the very closest application to business to prevent losses. Pretty good work is being done all along the line in the making of permanent improvements. You must understand that our trouble does not end at this season with merely telling people that they must not light fires. Fires will exist and it is our business to keep as close to them as possible in order to prevent them from spreading over large areas. Communication is our best weapon in this work and during the past few months we have been perfecting as far as possible our system of communication."

Quebec, Que.—After many complaints of the poor condition of the road, leading from the city to Lake Beauport, the Hon. J. E. Caron, Minister of Roads and the Hon. C. Delage, Speaker of the Legislative Assembly, have gone over the road with a view of securing some improvement. Lake Beauport is a beautiful spot, but the wretched roads prevent the extensive use of carriages or motors.

Vancouver, B.C.—For the purpose of taking up the question of a municipally owned power plant, Ald. McSpadden and Ald. McMaster were appointed by Mayor Baxter to act on a joint committee of representatives from the municipalities in Greater Vancouver.

The latest of numerous resolutions from ratepayers' associations, urging civic action towards a municipal power plant, came before the city council recently, from Kerrisdale Ratepayers' Association. It suggested a committee to gather information as to the operation of such a plant and the profits that might be derived from it, from cities which had made the experiment. Ald. Crowe favored a similar commission to that taking care of the sewerage system. He later, proposed the motion that the mayor appoint two delegates to a joint committee. Ald. McSpadden was chosen as chairman of the British Columbia Electric committee of the council.

At the last meeting of the city council, when a similar resolution came in from a ratepayers' association, it was referred to Mayor Baxter, who had intimated that the government was making a survey and a record of the water powers of the province. It was said that Mayor Baxter might look out for one for Vancouver.

Calgary, Alta.—Ald. M. C. Costello has signified the intention of proposing that the city take steps to investigate the question of filtering the water so that it will be pure and clean all the year around.

"Though the medical health officer tells us that even when the water is muddy the bacteriological count is very low, it seems to me that it is a bad thing to have muddy water at all. It must make a bad impression on visitors who come here and bad impressions are bad advertising. When we were in Saskatoon at the convention of the union of Canadian municipalities we had an oportunity to look over the filtration plant of that city and it struck us as being a most excellent scheme.

"A filtration scheme is greatly needed in Calgary, I think," he continued. "There is nothing like getting pure water. Though I hardly think there is any danger from the muddy water we have at times, it is my opinion that we should take no chances. The clearer and purer the water is, the better. The dirt should be taken out. Dirty water does not look pure and visitors to the city who turn the tap and are rewarded by a flow of dirty water, carry away a bad impression. It would pay the city in a great many ways to establish a filtration plant.

"In Saskatoon they have a small plant of small capacity, but Calgary would need one five or six times as large. Calgary needs eight or ten millions of gallons of water per day, while they get along in Saskatoon on one-fifth of that.

"I believe the very best possible system should be installed, if the scheme is viewed favorably. What that system is would have to be found out. Sand, charcoal, gravel, etc., are used in such systems."

Calgary, Alta.—City Water Engineer A. Ellison Fawkes reported to Commissioner A. G. Graves that the survey which the city is running to determine the cost of a pipe line for a mountain water supply has now been completed to within two miles of the present intake on the Elbow River. Mr. Fawkes estimates that it will require about two weeks more for the survey gang to get down to the present city reservoir, when the survey will be complete.

The work of compiling the data to secure estimates of the cost of the line is already under way and when finished will be most voluminous and complete.

"It will require two or three weeks longer after the survey is finished," said Mr. Fawkes, "to complete the estimates. Then we can take up the question of whether the city desires to go into the scheme proposed by Dr. Ings and take water from the tail race of the power plant he proposes. If the city does that, it will not have to build a dam. If it decides not to, a dam will have to be built. The difference in cost would be about $300,000."

Mr. Fawkes already has figures practically complete on the alternative cost of establishing Calgary's future water supply on a pumping and filtration basis instead of running the pipe line to the city forty-four miles from the Rocky Mountains. His preliminary figures on the pumping plant and filtration plant show that such a scheme would cost less than a million dollars, speaking in round numbers. The pipe line scheme will cost much more than a million, but the cost of maintenance in years to come would not be so great. These figures are on a forty million gallon per day basis.

Toronto, Ont.—Concrete bridge construction, while progress may be made in the future, has passed into stages of standard methods and is no longer experimental in so far as assured results are concerned, states F. A. McLean, in his annual report on highway improvement in Ontario for 1912. Past discussion has centred around the relative values of broken stone and gravel; wet and dry mixtures; methods of mixing, types of reinforcement and other details which now belong to settled practice.

Whatever specification is determined upon, however, should be carried out with intelligence, and in good faith. To this end, capable inspectors are necessary. Carefully drawn plans and specifications are of little value if their interpretation is left to men who have no proper knowledge of the properties of Portland cement and its use. Inspectors should be selected by the engineer, and should be carefully instructed before being placed on the work. Inspectors appointed by Boards of Works and councils, because of their influence, can rarely be expected to develop the skill, interest and enthusiasm that properly belong to the position and which are essential to best results. The writer has in the past found young engineering students of the second or third year to be in many respects well qualified, while the experience and training is of much value to them and ultimately to the public.

Better results could in many cases be had, were engineers to give more attention to form-work. Too frequently this is left to the rule-of-thumb methods of the foreman or contractor; whereas it is of vital importance that forms of adequate strength and of exact dimensions be provided if the strength and beauty of the structure is not to be jeopardized. Economy and perfect results will be greatly facilitated by detailed drawings for well-designed centres and forms.

Victoria, B.C.—Experiments will be made, under the direction of Water Commissioner Rust, to purify the water in Beaver Lake, which at present, owing to the presence of vegetable growth, is possessed of an offensive odor and color. An effort to precipitate the algae permeating the water, to the presence of which is ascribed the trouble, will be made by Assistant Engineer Foreman and City Analyst Birch. Recently they visited Beaver Lake and made arrangements to undertake the experiments. It is proposed to treat the water with sulphate of copper, bags of this substance to be pulled through the water. The chemical action consequent upon the introduction of the sulphate into the water, will, it is expected, precipitate the vegetable substances and thus clear the water.

The city has not yet been able to secure a full supply of clean sand for the renewing of the filter beds at Beaver Lake, but a small quantity has been secured and the filters can be used to some extent. It is expected, however, that the filter beds will be cleaned and renewed, when this method of cleaning the water from Elk and Beaver Lakes will be in full working order.

With these improvements, the supply from Elk Lake will be much more palatable, and can be mixed with the supply from Goldstream without any deterioration in the water supplied to consumers.

Toronto, Ont.—A special telegram received here from Boston, says efforts are being made by the Canadian Northern Railway to gain a terminal at Portland, Maine.

It is believed here that this step is only preliminary to an attempt to bring its lines into Boston in order to take advantage of the opportunity that the Grand Trunk failed to accept.

A company has already been organized and has obtained a charter to construct a railway from Portland to South Portland and to erect whatever terminal facilities may be needed there. This location offers the only available ground for a terminal at the Maine seaport and would make it possible for a transcontinental line to acquire a Portland entry to tidewater at comparatively low cost.

It is no secret that for some time the Canadian Northern Railway has long desired to enter Portland. Its effort to gain a terminal on United States territory and a share in New England trade led them to take steps toward acquiring rights to build south through Canada from Quebec and into the State of Maine.

Montreal, Que.—According to A. P. Davis, the contractor for the sub-structure of the Quebec bridge the work will be completed by November 15th. The St. Lawrence Bridge Company, which has the contract for the superstructure, will then commence. Mr. Davis expressed the opinion that it will take another four years to complete the bridge, and that it will not be ready for operation until 1917.

Toronto, Ont.—The International Joint Commission at Washington, which is making an investigation to determine what would be the most practicable level at which the Lake of the Woods should be maintained to best serve the interests of navigation, agriculture, power development, and fishing in that region between Canada and the United States, has sent out requests for certain information, the notices having been distributed widespread through the State of Minnesota. The Commission seeks information upon the following matters: The regulation, if any, of such secondary controlling works as exist in both Canada and the United States constructed for the floating of timber to the Lake of the Woods or tributary waters. When such works were installed, and the authority for them, the areas controlled by timber interests, and the extent to which timber has yearly been taken off such lands, and generally all information that would enable a concise report as to the progress of denudation, as well as any work, if any, in the way of reforestation. Data as to operations of all corporations engaged within the watershed of these boundary waters with the history of such corporations, conservation of the fisheries, and the possibilities of the future development of the region for tourist traffic.

Col. Geo. W. Goethals, chairman of the Isthmian Canal Commission and Chief Engineer of the Panama Canal, has consented to accept the honorary presidency of the International Engineering Congress, and will preside in person over the general sessions to be held in San Francisco, September 20-25, 1915.

PERSONAL.

HON. DR. ROCHE, Minister of the Interior, will begin a western tour of investigation about August 15th for the study of irrigation developments and necessities.

ARTHUR J. CANTIN, formerly sales engineer with the German Clancey and Grindley Company, Limited, of Edmonton, Alta., has been appointed superintendent of the Electric Light and Power Department of the town of Melville, Sask.

STANLEY LIGHTFOOT has taken over the Toronto business of Lloyd, Blackmore and Company, Ottawa, patent attorneys. The business will be owned by Mr. Lightfoot and conducted under his own name. The same office will be maintained in the Lumsden building.

L. C. GRAY, Ph.D., of Wisconsin University, and at present engaged in research work at the Carnegie Institute at Washington, has been appointed to a professorship at the University of Saskatchewan, Saskatoon. The research work of the institution will be in his charge.

The following members of the staff of the Faculty of Applied Science and Engineering, University of Toronto, have attained the rank of assistant professor in the department indicated: C. R. Young, structural engineering; W. M. Treadgold, surveying; J. R. Cockburn, drawing; M. C. Boswell, organic chemistry, and E. G. R. Ardagh, chemistry.

COMING MEETINGS.

ONTARIO MUNICIPAL ASSOCIATION.—Annual Meeting to be held in Toronto, August 28th and 29th. Secretary-treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ont.

THE NEW ENGLAND WATERWORKS ASSOCIATION.—Annual Convention to be held in Philadelphia, Pa., September 10th, 11th and 12th, 1913. Secretary, William Kent, Narragansett Pier, R.I.

THE ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Sixth General Annual Assembly will be held at Calgary, Alberta, September 15th and 16th. President, J. H. G. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Third Annual Meeting in Regina, September 18th, 19th and 20th. General Secretary, Major Lorne Drum, Ottawa; Local Secretary, R. H. Murray, C.E., Regina.

AMERICAN ROAD CONGRESS.—Annual Session will be held in Detroit, Michigan, from September 29th to October 4th. Secretary, J. E. Pennybacker, Colorado Building, Washington, D.C.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—Twentieth Annual Meeting to be held in Wilmington, Del., October 7th to 10th. Secretary, A. Prescott Folwell, 15 Union Square, New York.

UNITED STATES GOOD ROADS ASSOCIATION.—Convention will be held at St. Louis, Mo., November 10th to 15th. Secretary, J. A. Rountree, Lo21 Brown-Marx Building, Birmingham, Ala.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

AMERICAN CONCRETE INSTITUTE.—First Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

THE INTERNATIONAL ENGINEERING CONGRESS.—Convention will be held in San Francisco in connection with the International Exposition, 1915.

POWER DERIVED FROM REFUSE.

Those who have not followed the more recent developments in the disposal of city refuse, will find something instructive in a paper read by E. H. Foster before the American Waterworks Association at Minneapolis, Minn., in June. They will be surprised to learn that in a number of places part, if not all, of the steam used in driving steam pumps at waterworks pumping stations is derived from burning waste material. As a result of the development in the incinerator method of disposing of mixed refuse in England and in continental cities, several plants have been installed in this country, and, in all probability, the older and less sanitary methods hitherto in vogue will gradually give way to this more modern method, particularly as our cities increase in size.

Having produced the effect of destroying refuse in a sanitary and inoffensive manner, the question of how best to utilize this heat is answered by combining a steam boiler with the furnace and producing steam at any desired pressure. Steam so produced is available for running engines to produce electricity, but, as a rule, the amount which could be produced is but a small proportion of the total amount consumed by the community, also, the operation of the destructor does not lend itself to the requirements of peak loads which are incident to all lighting and power stations. A pumping load, however, is ideal for a destructor because of its uniformity and constancy, and it is in this direction that a municipality has its greatest opportunity for conserving this energy.

It would hardly be expected that the exact amount of steam available from the destructor would coincide with the exact amount of steam required at the pumping station, but the almost invariable condition is that the destructor steam is somewhat less than required by the pumps. Therefore, the difference is made up by auxiliary boilers.

The steam may be passed direct from the destructor to the steam range of the pumping station or converted into electricity and used to drive motor-driven pumps. Instances where steam from a destructor is used directly for driving pumps are found at Montgomery, Alt.; Westmount, Que., and Savannah, Ga., while instances where the power is first converted into electricity and the current used to drive motor-driven pumps to furnish the water are found at Milwaukee, Wis., and Savannah, Ga.

RUST-PROOF COATING FOR IRON OR STEEL.

This new rust-proof coating is a paint that is applied to the surface of the article to be coated and is then baked. The ingredients are mixed in the following proportions: Linseed oil, 25 parts; calcium resinate, 36 parts; manganese borate, ½ part; lead acetate, 1 part; naphtha, 37½ parts; artificial graphite, 25 parts. These are mixed and applied to the metal by brushing or dipping or any other method. The article is then baked at 300° F. for 1 hour and 40 minutes. The coating is stated to be highly lustrous and resistant to corrosion. No other form of graphite gives satisfactory results.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for smal fee.

19900—July 25—Approving location C.P.R. station at Corwhin, E. ½ Lot 21, Con. 19, Tp. Puslinch, Co. Wellington, Ont.; provided whenever it develops that traffic on highway is blocked for more than five minutes at any one time by reason of location hereby approved, Board shall be at liberty to relocate said station.

19901—July 25—Authorizing rural municipality of Webb, No. 138, Sask., at its own expense, to construct and maintain crossings over C.P.R. at Antelope, Gull Lake and Seward, Saskatchewan.

19902—July 25—Authorizing G.T.P. Ry. to carry traffic on portion of main line east of Prince Rupert, B.C., between Beament, mileage 195, and Morricetown, mileage 205; provided trains be operated over said portion at a speed not exceeding twenty-five (25) miles an hour.

19903—July 23—Authorizing T., H. & B. Ry. to construct interlocking plant where it crosses Hamilton St. Ry., on Barton St. East, Hamilton, Ont.

19904—July 24—Authorizing C.L.O. & W. Ry. (C.P.R.) to construct across William St., town of Cobourg, Ont. (West Riding), at mileage 120.34 from Glen Tay, by means of a bridge.

19905—July 25—Directing that, within ninety (90) days from date of this Order, C.P.R. install improved type of illuminated electric bell at crossing of highway at mileage 0.91 from St. Martin's Jct., Que., and thereafter maintain bell at its own expense; 20 per cent. of cost of installing bell to be paid out of the Railway Grade-Crosing Fund, remainder by railway company.

19906—July 22—Directing that signboards be erected and maintained at crossings on farm of Charles Sherriff, Huntingdon, Que., crossed by G.T.R. and N.Y.C. & H.R.R., and words printed thereon in large white letters to effect that such crossings are not to be blocked, and crossings must not be obstructed for a longer period than 5 minutes at any one time; this Order becomes effective within ten days from its date, and that railway company be liable to penalty of one hundred dollars for each violation of or failure to comply with provisions of this Order.

19907—July 25—Directing that, within 60 days from date of this Order, Pere Marquette Ry. install and put in working order an improved type of automatic electric bell at crossing of highway one and three-quarter miles west of Kingsville, Ont., and shall thereafter maintain bell at its own expense; 20 per cent. of cost of installing bell to be paid out of the Railway Grade-Crossing Fund, remainder by railway company.

19908—July 25—Approving location of C.P.R. station at North Appin, Tp. of Ekfrid, Co. Middlesex, Ont.

19909—July 26—Approving change in location plan of Campbellford, Lake Ont. and Western Ry. (C.P.R.) so as to include extra land required for station grounds in Lot 29, and 30, Con. 2, Tp. of Pickering, County of Ontario, Province of Ontario, and approving location of station known as "Cherrywood" on same property. (Mileage 175.39.)

19910—July 26—19911—July 28—Authorizing Dominion Atlantic Railway to operate its trains over bridges over Sissiboo River, County of Digby, N.S., and over Gaspereaux River, at Horton Landing, in the County of Kings, N.S.

19912—July 25—Directing the Campbellford, Lake Ont. and Western (C.P.R.) to construct suitable farm crossing for J. D. Howden, of Whitby, Ont., where it crosses his farm in Lot 24, Con. 2, Tp. of Whitby, Co. Whitby, Ont.

19913—July 28—Authorizing G.T.P. Ry. to construct an extension of its elevator tracks across road allowance, in its station grows in Town of Biggar, Sask.

19914—July 28—Authorizing C.P.R. to construct with its second track (double track) across fourteen highways on its Broadview Subdivision, Manitoba Division. Mileage 8.75 to 18.25.

19915—July 29—Authorizing C.P.R. to construct a spur for John MacGregor Company at mileage 45.16 from Aroostook Junction, Edmundston Subdivision into Lot 2, Parish of St. Basil, Co. of Madawaska, N.B.

19916—July 24—Re protection of G.T.R. crossing over Yonge street, 1.5 miles south of Aurora, Ont., mileage 28.66. Side road to be diverted into Yonge street. Land to be deeded to the township by the G.T.R. Work to be performed by the Tp. of King. Electric bell to be installed at crossing of Yonge street within sixty days; 20 per cent. from Ry. Grade Crossing Fund.

19917—July 26—Approving location of C.P.R. station on Lot 6898, Group 1, West Kootenay Dist., at Canyon, B.C., near mileage 63, Sirdar Subdivision.

19918—July 28—Approving plan "A" showing details of interlocking plant of C.N.O. Ry. and C.N. Montreal Tunnel and Terminal Co. with Jacques Cartier and Union Railway Company, near Jacques Cartier Junction, Province of Quebec.

19919—July 31—Directing G.T.R. to construct a siding to connect with existing siding for Greenfield Conduit Company, Limited, and others who may wish to use same in the rear of Broadview avenue, Toronto, Ont.

19920—July 24—Amending Order No. 19348 of May 16, 1913, re cattle pass on C.N.O. Ry. for John Fletcher and John Wilson the following clause: "That, in respect of the cattle pass to be constructed for the said John Wilson, the railway company be not responsible for the drainage."

19921—July 25—Authorizing C.P.R. to construct spur for Revelstoke Saw Mill Co., Ltd., across Fifth avenue and Block 123, in Town of Swift Current, Sask.

19922—July 28—Amending Order 19856, dated July 12, 1913, directing Brockville, Westport and N.W. Ry. Co. to construct a cattle pass for D. H. Grey and C. S. Grey by adding following clause: "The said cattle pass to be constructed and completed within sixty days from the date of this Order."

19923—July 28—Authorizing C.P.R. to construct spur for the Saskatchewan Motor Co., Limited, Regina, Sask.

19924—July 26—Authorizing G.T.R. to construct sidings to premises of Alabastine Hard Mortar, Limited, the York Sand and Gravel, Limited, and the York Sandstone and Brick Co., Limited, Tp. of Scarboro, Co. of York, Ont.

19925—July 31—Dismissing application of G. C. Cummings, of Lyn, Ont., to compel G.T.R. to construct a subway between Lyn and Brockville, on Lot 21, Con. 1, Tp. of Elizabethtown, mileage 127.77 from Montreal.

19926—July 31—Approving agreement dated July 29, 1913, providing for proposed new viaduct and plans and profiles referred to in agreement and dated April 25, 1913, agreement made between the City of Toronto, the railway companies (C.P.R. and G.T.R.), Toronto Harbour Commissioners. Work to be completed within three years from July 29, 1913.

19927—July 31—Amending Order No. 19288, of May 12, 1913, re compensation to be paid W. B. Fee by G.B. and S. Ry. (C.P.R.) by adding after the word "diversion" in the fifth line of the operative part of the Order the following words: "Mr. W. B. Fee to be paid whatever damages he is entitled to for the land, for severance and all other damages flowing directly from that cause."

19928—July 30—Authorizing the Vancouver, Victoria and Eastern (G.N.R.) to take certain lands in the District of New Westminster, B.C., and to construct bridge over its tracks on the line of the North road, with roadway and sidewalks. Municipalities of New Westminster, Burnaby, Port Moody and Coquitlam represented.

19929—July 29—Authorizing G.T.R. to construct sidings for Harris Abattoir Company, Limited, north of St. Clair avenue, Toronto, Ont., crossing Symes road.

19930—July 29—Approving location of G.T.P. station at mileage 428.5, Prince Rupert East, Lot 3338, Cariboo District, B.C.

19931—July 29—Approving location of Campbellford, Lake Ontario and Western Ry. (C.P.R.) station at Grafton, in Lot 23, Con. A, Tp. of Haldimand (West Riding), Ontario.

19932—July 29—Authorizing C.P.R. to construct with its double tracks across highway diversion at mileage 84.99 from Moose Jaw, Swift Current Subdivision. Present road allowance to be diverted.

19933—July 29—Approving location of C.P.R. station on the N.E. quarter of Sec. 10, Tp. 8, Rge. 30, West 2nd, Sask.

19934—July 28—Authorizing C.P.R. to construct diversion of highway and cross same at mileage 77.91 from Moose Jaw on Swift Current Subdivision. Present road allowance to be diverted.

19935—July 28—Approving revised location of C.P.R. from mileage 65.94 to 68.04 and construction of additional double track between mileage 65.94 and 69.24 (zero of said mileage being at Broadview, Sask.) and to construct across three highways.

19936—July 31—Directing that C.P.R. make connection with C.N.R. spur to Government Elevator at Port Arthur, Ont., within thirty days, cost to be paid by Board of Grain Commissioners, also to be used by G.T.P.

19937—August 5—Approving G.T.P. Standard Freight Mileage Tariff C.R.C. No. 18, to apply between stations in Alberta and British Columbia, between and including Thornton, Alberta, and mileage 1189, British Columbia.

19938—July 30—Approving By-law No. 40, Hull Electric Ry., covering rules and regulations for the government of employees of the Hull Electric Company.

19939—July 19—Approving revised location C.L.O. and W. Ry. in Lot 23, Con. A, Tp. of Brighton, and authorizing the applicant company to take from the G.T.R. the extra land required for right-of-way.

19940—July 30—Authorizing the C.P.R. to construct, maintain and operate a branch line of railway or spur for the Regina Storage and Forwarding Co., Regina, from a point on the existing spur in Block 137, thence across Lots 1, 2 and 3, Block 137, City of Regina.

19941—July 29—Approving revised location C.P.R. from a point in Sec. 21 at mileage 66.7, thence to a point in Sec. 7 at mileage 69.6 from Moose Jaw on the applicant company's Swift Current Subdivision.

19942—July 30—Authorizing C.P.R. to construct spur for De-Laval Dairy Supply Co., Limited, Peterboro, Ont.

19943—July 29—Approving location Edmonton, Dunvegan and British Columbia Ry. Co. through Tps. 71-72, Ranges 1-4, West of the Fifth Meridian, from mileage 128.44 to mileage 156.11.

19944—July 30—Authorizing G.T.R. to construct, maintain and operate a branch line through the premises of the Toronto Structural Steel Co., Limited, Western Ontario.

19945—August 2—Amending Order No. 15090, dated October 11, 1911, which authorized City of Hamilton to construct a subway on T.H. and B. at Birch avenue, by striking out the words applicant company and substituting T.H. and B. Ry.

19946—July 31—Authorizing C.P.R. until August 1, 1913, to operate its trains over crossing G.T.R. at Tecumseh street, Toronto.

19947—July 29—Authorizing Kingston and Pembroke Ry. to construct spur for the Chandler Jones Lumber Co., in the Tp. of Palmerston, Ont.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

RAILWAYS—STEAM AND ELECTRIC.

+—Hope, B.C.—MACARTHUR BROS. COMPANY, engineers and contractors, New York City, has just been been awarded the contract for the construction of thirty-eight miles of railroad by the Kettle Valley Railroad Company jointly with the Great Northern Railroad Company. This work is located in the Coquehalla Canyon, British Columbia, and it is estimated that the cost of construction will exceed $2,000,000. The work consists of considerable heavy rock work and several small tunnels. Mr. F. C. Hitchcock, vice-president and general manager of MacArthur Brothers Company, is in charge of this work and has established headquarters at **Hope, British Columbia,** where he intends to sublet a portion of the work at once.

▲—St. Malo, Que.—Tenders will be received up till the 2nd of September, 1913, for the erection of locomotive and car shops. Plans and specifications may be obtained from Mr. Gordon Grant, Chief Engineer, Ottawa; Mr. A. E. Doucet, District Engineer, Quebec, and the Commissioner of the Transcontinental Railway, Ottawa. P. E. Ryan, Secretary.

BRIDGES, ROADS AND PAVEMENTS.

Calgary, Alta.—The Mineral Rubber Company has made a demand on the city commissioners that it be allowed to do 15,000 yards more paving, but it is not likely the demand will be complied with. The subject was considered at the meeting of the commissioners recently. When the paving contracts were awarded last year the Mineral Rubber Company was given 100,000 yards, but when the contracts were let certain streets were allotted to the company, the paving on which was 15,000 less than the award. The company consented to the council reducing its award to 85,000 yards when the contracts came to be drawn up. Like all the other companies to which contracts were given, with the exception of the Crown Paving Company, the Mineral Rubber Company failed to complete its contract, and was, therefore, subject to having its contract for what was left over cancelled. The commissioners, however, saw fit not to cancel it, but allowed the company to go on and finish up this season. Commissioner Samis stated at the meeting that he did not consider it advisable to do any paving except by the city plant this year. The matter was left to Commissioner Samis and the city solicitor.

Canora, North Saskatchewan.—Tenders will be received up till August 18th, 1913, for the construction of two reinforced concrete bridge abutments for a bridge over the Whitsand River. Plans and specifications may be obtained from A. J. McPherson, chairman, Board of Highway Commissioners, Regina, Sask.

Chatham, N.B.—The Department of Public Works, Ottawa, has stopped all work on the new bridge across the Miramichi River from Newcastle to a point below Nelson. This action has been taken as a consequence of not complying with the regulations which affect the building of bridges or wharves on navigable rivers. The construction will begin again when the plans are furnished and approved by the Department of Public Works, at Ottawa.

+—Jacksonville, Fla.—The DOLARWAY PAVING COMPANY have been awarded the contract for the construction of 26,141 square yards of pavements.

Kamsack, North Saskatchewan.—Tenders will be received up till August 18th, 1913, for the construction of two reinforced concrete bridge abutments for a bridge over the Assiniboine River. Plans and specifications may be obtained from A. J. McPherson, chairman, Board of Highway Commissioners, Regina, Sask.

+—London, Ont.—The City Council has awarded Messrs. BAIN & ROSS the contract for the substructure of the Wharncliffe Road bridge.

London, Ont.—Tenders will be received up till August 18th, 1913, for the construction of approximately 5,430 square yards of reinforced concrete pavements with 4,230 lineal feet of cement curb. Plans and specifications may be obtained from W. N. Ashplant, City Engineer.

Moose Jaw, Sask.—Work is proceeding rapidly on the big bridge which is being built for the Canadian Northern Railway across the South Hill Ravine, and it will be completed in a very short space of time. Already more than half of the bridge has been completed and one of the piers has been erected for the bridge, which will give the company entrance into the central portion of the town, and the pile-driver is now on the north side of the river. There is a large amount of trestle work and bridging to be done between South Hill and the point where the roadbed will strike the level, about Fairford Street East, but this will not take long, now that an active start has been commenced. Reports say the company will start work next week on a station in South Hill.

Osgoode, Ont.—Tenders will be received up till August 18th, 1913, for the building of a concrete bridge opposite Lot 22, Concession 7. Plans and specifications may be obtained from Chas. Macnab, County Clerk, Court House, Ottawa.

Ottawa, Ont.—Tenders will be received up till the 6th of September, 1913, for the construction of a substructure of a bridge at Smith Falls. Plans and specifications may be obtained from the Department of Railways and Canals, Ottawa. L. K. Jones, Secretary.

Preeceville, North Saskatchewan.—Tenders will be received up till August 18th, 1913, for the construction of two

Tarvia

Preserves Roads
Prevents Dust~

Beaurepaire Road, Beaconsfield, Quebec. New macadam road treated with two coats of "Tarvia B."

A New Principle in Road Building

IT has long been recognized by engineers that one of the greatest causes of the destruction of macadam roads by traffic has been the internal movement caused by the passage of heavy loads. The endless shifting and creeping of the lower courses of stone causes a grinding and pulverization which destroys the stone and breaks the bond.

To reduce this internal movement engineers have buried the larger stone under successive layers of finer stone. This fine stone forms dust more rapidly but the dust serves to protect the foundation of the road by acting as a cushion. Modern traffic makes the use of such dust cushions quite impracticable, for the automobiles not only stir up the dust but they create entirely new conditions by scouring the surface of the road and breaking the bond with the backward thrust of their driving wheels.

The possibility of making roads automobile-proof by using Tarvia as a binder from top to bottom of the wearing-course during the construction of the road has now been satisfactorily demonstrated. The Tarvia fills the voids and forms a tough, durable matrix in which the stone cannot shift or grind. Consequently it has become possible to use large stone in a much greater proportion of the construction. The fine screenings and stone chips are used only on the surface as a finishing coat

Traffic wearing away the surface strikes the layer of large stone in the Tarvia matrix and makes little or no impression upon it. The large stone pulverizes but slowly and cannot be torn loose by automobile wheels. It does not change contour, sheds water instantly, is free from dust, costs but a trifle more to build than ordinary macadam, costs much less to maintain.

THE PATERSON MANUFACTURING COMPANY, LIMITED
MONTREAL TORONTO WINNIPEG VANCOUVER

THE CARRITTE-PATERSON MANUFACTURING CO., LIMITED
ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

reinforced concrete bridge abutments for a bridge over the Assiniboine River. Plans and specifications may be obtained from A. J. McPherson chairman, Board of Highway Commissioners, Regina, Sask.

Regina, Sask.—Tenders will be received up till August 23rd, 1913, for the construction of grade, North Sections 21 and 22, Township 33, Range 19, West Third Meridian. Plans and specifications may be obtained from A. J. McPherson, chairman of the Board of Highway Commissioners.

Rosthern, Sask.—The Town Council has accepted an offer of 87½ per cent. and accrued interest for $10,000 sidewalk debentures from the Imperial Bank of Canada. In view of the condition of the money market the price is considered fair.

+—**Russell, Man.**—Mr. O. DANNELS, Bredenbury, has been awarded the contract for the construction of cement sidewalks here.

+—**Sandwich, Ont.**—The City Council has awarded Mr. THOS. CHICK, Windsor, the contract for the construction of 16,000 square yards of concrete pavement. The contract price is $26,000.

Saskatoon, Sask.—Work will be commenced on the new traffic bridge across the South Saskatchewan River, being erected by the Provincial Government and the city at a cost of $398,000.

+—**Springfield, Ill.**—The DOLARWAY PAVING COMPANY have been awarded the contract for the construction of 1,216 square yards of pavements.

St. Jean, Que.—The municipal council has awarded Messrs. BARABE & JACQUES, Deschailons, the contract for the construction of a bridge over the Duchem River. The contract price is $17,500.

Victoria, N.S.—Tenders will be received up till August 23rd, 1913, for the following bridges and culverts: Road Jersey Cove to Smokey, 23.2 miles, 90 culverts. Road Lower Middle River to Inverness, County Line, 13.7 miles, 72 culverts. Road Baddeck to Inverness County Line, via Nyanza, 16.6 miles, 105 culverts. Road Baddeck to Englishtown, 18.0 miles, 95 culverts. Plans and specifications may be obtained from Road Commissioner, Halifax, N.S., and also at the offices of the following: John G. Morrison, Esq., Englishtown, N.S.; M. D. McAskill, Esq., Baddeck, N.S.; A. K. MacKenzie, Esq., Nyanza, N.S.; David A. MacRae, Esq., Middle River, N.S. E. H. Armstrong, Commissioner of Public Works and Mines.

+—**Winnipeg, Man.**—The City Council has awarded Messrs. ALLOWAY & CHAMPION and the CANADA MINERAL RUBBER COMPANY equal contracts for supplying refined asphalt. The UNION OIL COMPANY, Chicago, the contract for supplying fluxing oil. The contract price is $20 per ton.

LIGHT, HEAT AND POWER.

Aurora, Ont.—The ratepayers of the town have passed a by-law calling for an expenditure of $16,000 for the purchase and installation of electrical machinery and apparatus.

+—**Carlyle, Sask.**—The John Galt Engineering Company have awarded the following contracts in connection with the $20,000 extension of the waterworks in order to supply the Canadian Northern Railway, and $10,000 for electric light and power works: Power house and reservoir and erection of compressor, BENNET DEBNAM COMPANY, Calgary, pumps, CALEDONIAN IRON WORKS, Calgary; generators, GENERAL SUPPLY COMPANY, Calgary; meters, PACKARD ELECTRIC COMPANY, Winnipeg; poles, McKINNON COMPANY, Calgary; line material, NORTHERN ELECTRIC COMPANY, Winnipeg; wire, E. F. PHILLIPS COMPANY, Winnipeg; transformer, CANADIAN MALONEY COMPANY, Winnipeg; street lighting equipment, N. E. F. PRINGLE, Winnipeg; wiring line, E. SMITH, Melville Sask.

Hamilton, Ont.—Tenders will be received up till August 28th, 1913, for the installation of a joint underground conduit system for the Hamilton Hydro-Electric, the Dominion Power and Transmission Company and the telegraph companies. Plans and specifications may be obtained from the Hamilton Hydro-Electric Department. E. I. Sifton, Consulting Engineer.

Medicine Hat, Alta.—Electric wiring in the business portion of the city of Medicine Hat is becoming inadequate, and the work has been commenced on the alteration of part of the distribution system. It is proposed to place these wires on 45-ft. poles in order to avoid danger from contact with telephone and fire alarm wires.

+—**Winnipeg, Man.**—The City Council has awarded the FORT GARRY CONSTRUCTION COMPANY the contract for the new terminal power station for the light and power department. The contract price is $35,000.

GARBAGE, SEWAGE AND WATER.

Fort William, Ont.—The report on sewage disposal in the township of Neebing, adjoining this city, has been completed by Engineer William C. Sample, and will be presented at the August meeting of the council of the municipality. This report deals with a scheme for adequate drainage for the site of some five hundred houses to be erected.

Medicine Hat, Alta.—During the month the water distribution system of Moose Jaw has been extended by 6,413 feet of 6-inch and 213 feet of 8-inch pipe. In all, 27 new 6-inch valves were installed and 62 new connections made. In addition to this, the work of connecting the new main from the standpipe to the new power house was completed and a temporary connection to the pump was finished. In connection with this some 624 feet of 8-inch pipe were laid between the well and the end of the 20-inch main.

Port Arthur, Ont.—The council of the corporation intends to construct sewer and water mains on Secord Street from Pearl Street northwards to Armory Building, and intends to specially assess a part of the cost upon the land abutting directly on the work. The estimated cost of the construction of the sewer is $300 and of the water main $220.

+—**Regina, Sask.**—The City Council has awarded the CANADIAN IRON CORPORATION, Fort William, the contract for supplying 4,000 cast-iron pipe to be used for waterworks construction.

+—**The Pas, Man.**—The Town Council has awarded the HURST ENGINEERING AND CONSTRUCTION COMPANY, Winnipeg, the contract for sewer pipe. The contract price is $76,920.

Toronto, Ont.—Tenders will be received up till August 26th, 1913, for the supply and erection of three motor-driven centrifugal sewage pumps, automatically controlled. Plans and specifications may be obtained from R. C. Harris, Commission of Works, City Hall, Toronto. H. C. Hocken, Mayor.

Victoria, B.C.—The following tenders have been received in connection with the Sooke water supply. These were referred to the Water Commissioner and Consulting Engineer Meredith. For the concrete pipe line of 27½ miles long from Sooke Lake to Humpback Reservoir: M. P. Cotton & Company, $2.38 a foot, $342,720; Ross Nichols & Company, $2.38 a foot, $342,720; Pacific Lock Joint Pipe Company, $2.29 a foot, $329,760; Graff Construction Company, Limited, Seattle, $214 a foot $308,160; Arthur S. Bent, $2.38 a foot, $342,720; Reinforced Concrete Pipe Company, Limited, $3.25 a foot, $468,000. For riveted steel pipe for the pressure line, ten and quarter miles long: Cumming & Kiehl, $529,730.50, divided into sectional bids for excavation, pipe-laying, filling, concrete piers, riveted steel pipe of 5-16 of an inch, and also of ⅜ of an inch in thickness, construction of gate-house, and other oddments. McDonald, Godson & Company, $444,988; Jones & Rant, Limited, $398,263; Andrew Grey & Company, $477,296. There were also four tenders for the steel trestles, the figures varying according to the class of material to be used, and tenders also for various minor materials required in the prosecution of the contract. In connection with the concrete pipe the Union Contracting Company wrote withdrawing a bid, and stating they did not wish to tender. Only two of the contractors who bid on the original specification in December, 1911, are again in the field after business.

INDUSTRIAL WORKS.

Cascades Point, Que.—Tenders will be received up till August 20th 1913, for rebuilding head of Guard Pier, lower entrance, Soulanges Canal. Plans and specifications may be obtained from the Chief Engineer of the Department of Railways and Canals, Ottawa, and also at the office of the Superintending Engineer, Quebec Canals, Birks Building, Montreal. L. K. Jones, Assistant Deputy-Minister and Secretary.

Gravelburg, Ont.—Tenders will be received up till the 25th of August, 1913, for the interior fittings of a post-office. Plans and specifications may be obtained from H. T. Mollard, Regina, and the Department of Public Works, Ottawa. R. C. Desrochers, Secretary.

MANNESMANN TUBES

Six Hundred Authorities Are Using Mannesmann Tubes

in Great Britain in varying quantities up to 15 miles; in Canada, to 17 miles.

Seven hundred miles of weldless steel spigot and faucet tubes —quite apart from flanged tubes and lapwelded spigot and faucet tubes—are in use in the United Kingdom, as well as large quantities in Canada, Australia, South Africa, South America, India, China, New Zealand and Europe.

We are constantly adding new customers to our list, and, what is of even greater significance, more frequently still receiving repeat orders.

Solid drawn tubes are used in places where it is impossible to use cast-iron pipes or lapwelded tubes, as well as in places where the conditions are more normal.

In the past five years the sale of Mannesmann weldless steel spigot and faucet tubes (home trade alone) increased one thousand per cent., and during the last financial year reached the figure of about 5,000 tons, equal to 15,000 tons of cast-iron, in addition to a large export business.

MANNESMANN TUBE CO. LIMITED

59 Victoria Square, MONTREAL

BOOKLETS ON REQUEST

Guelph, Ont.—The city has disposed of $8,396 of waterworks debentures, and expect to sell $72,448 more directly.

Levis, Que.—A contract has been let by the Transcontinental Railway Commission for a considerable amount of dredging in connection with the new car ferry dock at Levis.

+—Montreal, Que.—The Dominion Government has awarded the J. T. SCHELL COMPANY, Alexandria, Ont., the contract for the interior fittings of postal station "B."

Ottawa, Ont.—Tenders will be received up till the 18th of August, 1913, for the cutting of dead timber in Alberta. Plans and specifications may be obtained from the Department of the Interior, Ottawa. L. Pereira, Secretary.

Ottawa, Ont.—The Cabinet Council has awarded the following contracts: To the PACIFIC DREDGING COMPANY at Pitt River, B.C., $158,220; to BROLEY & MARTIN, New Westminster, B.C., for completion of the jetty at Steveston, B.C., $83,500; to PIERSON U. BAR COMPANY, for greenhouses and hot water heating in connection with experimental farm, $19,447. The Government has also passed an order-in-council purchasing from Hugo Carstairs a site in Winnipeg for a postal station, $35,000.

Quebec, Que.—Tenders will be received up till the 25th of August, 1913, for the installation of hot water heating apparatus in the citadel armory. Plans and specifications may be obtained from the Department of Militia and Defence, Ottawa. Eugene Fiset, Deputy Minister.

+—Sault Ste. Marie, Ont.—The Dominion Government has awarded the SOO DREDGING AND CONSTRUCTION COMPANY the contract for dredging. The contract price is $162,000.

South Vancouver, B.C.—Sonth Vancouver is discussing the question of indnstrial sites and the prospects of a municipality-owned gas plant.

St. Malo, P.Q.—Tenders will be received up till September 2nd, 1913, for the construction and erection, complete, of a locomotive and car shop repair plant. Plans and specifications may be obtained from Mr. Gordon Grant, Chief Engineer, Ottawa, and also at the office of Mr. A. E. Doucet, District Engineer, Qnebec, P.Q. P. E. Ryan, Secretary.

The Pas, Man.—Tenders will be received up till the 20th of August, 1913, for the construction of a sedimentation basin and foundations for a power house. Plans and specifications may be obtained from Murphy & Underwood, Saskatoon, and H. H. Elliott, Secretary-treasurer.

+—Toronto, Ont.—Messrs. C. W. WOOD & SONS, LIMITED, have been awarded the masonry contract on the Dominion Glass Company's factory on Dovercourt Road by Mr. J. Francis Brown, Board of Trade Building.

+—Vancouver, B.C.—The Hudson Bay Company has awarded the WHINSTONE MACADAM QUARRIES COMPANY the contract for supplying 10,000 cubic yards of crushed rock.

Victoria, B.C.—The City Commisssioners have received the following tenders for a telephone service in connection with the Sooke water supply: For the telephone service: Jones & Rant, Limited, $635 a mile, $15,875; Hinton Electric Company, $270 a mile, $18,000; Ocean Accident and Guarantee Company, through W. B. Morgan & Company, $13,425; Frank H. Folsom, $345 a mile, $8,625; P. E. Sommers, $488.50 a mile, $12,212.50. These were referred to the Water Commissioner and Consulting Engineer Meredith.

Victoria Harbor, Ont.—Tenders will be received up till September 8th, 1913, for the construction of a wharf at Victoria Harbor. Plans and specifications may be obtained from the Toronto Builders' Exchange, Toronto.

▲—Welland, Ont.—Tenders will be received up till the 27th of August, 1913, for the third section of the Welland ship canal. Plans and specifications may be obtained from the Department of Railways and Canals, Ottawa. L. K. Jones, Secretary.

MISCELLANEOUS.

Albert County, N.B.—Tenders will be received up till September 2nd, 1913, for construction of an extension to the breakwater at Upper Salmon River. Plans and specifications may be obtained from R. C. Desrochers, Secretary, Department of Public Works, Ottawa, and at the offices of F. C. Goodspeed, District Engineer, Chatham, N.B.

+—Beauport, Que.—The Dominion Government has awarded Mr. CELESTIN PARENT the contract for the erection of a drill hall. The contract price is $30,000.

Brampton, Ont.—Tenders will be received up till August 18th, 1913, for the construction of a clock tower, public building. Plans and specifications may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, Secretary.

+—Brampton, Ont.—W. A. THORN, of Collingwood, has been awarded the contract for a drill hall. The contract price is $16,000.

+—Edmonton, Alta.—The school board has awarded Messrs. BROWN & HARGREAVES the contract for the erection of a school building. The contract price is $160,000.

+—Edmonton, Alta.—The Canadian Consolidated Rubber Company has awarded the CANADIAN STEWART COMPANY the contract for the erection of a warehouse. The contract price is $120,000.

+—Fort William, Ont.—The CANADIAN STEWART CONTRACTING COMPANY has been awarded the contract for the erection of the new Whalen building. The contract price is $450,000.

+—Fort William, Ont.—The McDonald Wholesale Company has awarded Messrs. G. W. ALEXANDER & COMPANY, Winnipeg, the contract for the erection of a large wholesale house. The contract price is $50,000.

+—Greenwood, B.C.—The Dominion Government has awarded Messrs. JOHN BEMIS & SON the contract for the construction of a public building. The contract price is $41,000.

+—Hampton, N.B.—The Dominion Government has awarded the BRITISH AMERICAN CONSTRUCTION COMPANY, LIMITED, St. John, the contract for the erection of a post-office. The TRUSSED STEEL COMPANY, Halifax, were awarded the contract for the reinforced concrete.

+—Kemptville, Ont.—The Dominion Government has awarded Mr. JOHN DILLON the contract for the erection of a drill hall. The contract price is $11,800.

+—Millbrook, Ont.—R. SHEEHY has been awarded the contract for a drill hall. It will cost $11,000.

+—Montreal, Que.—The WHITE CONSTRUCTION AND REALTY COMPANY, have been awarded the contract for the erection of a moving picture theatre. The contract price is $15,000.

+—Montreal, Que.—The Dominion Government has awarded the following contracts for the erection of Grenadier Guard armory: General contract, concrete, plastering and painting, D. G. LOOMIS & SONS; steel and metal lockers and electric not let; roofing, CAMPBELL, GILDAY COMPANY, LIMITED; heating and plumbing, HICKEY & AUBUT.

+—Montreal, Que.—The Dominion Government has awarded Mr. C. E. DEAKIE the contract for the erection of postal station "H." The contract price is $200,000. The ARGENTEUIL GRANITE COMPANY the contract for supplying the granite.

Nelson, B.C.—Tenders will be received up till August 25th, 1913, for the erection and completion of a vault for the land registry at Nelson, in the Ymir electoral district. Plans and specifications may be obtained from Mr. W. F. Teetzel, Government Agent, Nelson; J. E. Griffith, Public Works.

New Westminster, B.C.—Tenders will be received up till August 19th, 1913, for the erection and completion of addition to the Land Registry office. Plans and specifications may be obtained from S. A. Fletcher, Government Agent, New Westminster; J. Mahony, Government Agent, Vancouver, and also J. E. Griffith, Department of Public Works, Victoria, B.C.

+—North Battleford, Sask.—The Dominion Government has awarded Messrs. PIGOTT & HEALEY Picton, Ont., the contract for the erection of a drill hall.

Ottawa, Ont.—Tenders will be received up till the 25th of August, 1913, for the erection of two residences on the experimental farm. Plans and specifications may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, Secretary.

Ottawa, Ont.—The contract for the piers at Carleton Head has been awarded to ROGER MILLER, of Toronto. The price is $949,250.

Manufacturers of Boilers, Castings, Condensers, Elevators, Engines, Filters, Forgings, Hydraulic Machinery, Pumps, centrifugal and reciprocating, Steam Turbines, Tanks, Water Wheels, Water Works Plants.

The Hampton Sedimentation Tank

Used in connection with an electrolytic hypochlorite treatment, the process is **ABSOLUTELY ODORLESS** and the effluent is free from disease germs.

Nine years of operation in large and important installations in England have demonstrated that an effluent exceptionally low in suspended solids and as free from odor as the entering sewage may be obtained with The Hampton Tank.

The Hampton Tank reduces the cost of any subsequent treatment.

Write for leaflet showing construction of the tank and explaining the special features of its design which make it particularly successful. This tank is not an experiment. It has been used for nine years with most satisfactory results, and has **PROVED** its efficiency and economy.

Leaflet on request.

specifications may be obtained on application to Mr. James Johnston, Chief Electrician, Department of Public Works, Ottawa. R. C. Desrochers, Secretary.

+—**Prince Albert, Sask.**—The Bank of Nova Scotia has awarded Mr. R. CLUNIE the contract for the erection of a new bank building.

Prince Albert, Sask.—The building permits for the month of July amounted to $171,000. For the same month last year they amounted to $300,550. This is a decrease of $129,550.

+—**Prince Rupert, B.C.**—The Premier Hotel Company has awarded Mr. C. L. WILLIAMS the contract for the erection of a five-story hotel. The contract price is $50,000.

+—**Red Deer, Alta.**—The Dominion Government has awarded Messrs. NESBITT & MILLER the contract for the erection of a drill hall. The contract price is $36,000.

+—**Red Deer, Alta.**—NESBITT & MILLER have been awarded the contract for a drill hall. The contract price is $36,000.

+—**Regina, Sask.**—The Tenn Manufacturing Company has awarded SMITH BROTHERS & WILSON the contract for the erection of an implement factory. The contract price is $40,000.

+—**Simcoe, Ont.**—The Dominion Government has awarded ROBERT E. GUNTON the contract for the erection of an armory. The contract price is $30,000.

Steelton, Ont.—Tenders will be received up till September 9th, 1913, for the construction of a public building. Plans and specifications may be obtained from Thomas R. Wilks, 612 Queen Street Sault Ste. Marie.

Toronto, Ont.—At a recent investigation into a large number of serious fires that have occurred in Toronto lately, Fire Chief Thompson recommends the expenditure of $100,000 on additional motor equipment. He recommends steam fire engines equipped with tractors for the mid-level districts. The opinion of the chief was against motorizing the whole department at once, but he recommends a partial installation of motor-drawn equipment.

Welland, Ont.—The building permits for the month of July this year amounted to $89,710. For the same month last year they amounted to $46,241. This is an increase of $43,469.

+—**Winnipeg, Man.**—The following contracts have been awarded in connection with the Manitoba Medical College: General contractors, masonry and carpentry, BLOW BROS.; iron and steel, VULCAN IRON WORKS; roofing, A. B. ORMSBY COMPANY; painting, R. CRAWFORD; heating, G. L. STEPHENSON; electrical, WM. McDONALD & WILSON.

Winnipeg, Man.—Tenders will be received up till the 25th of August, 1913, for new rifle range. Plans and specifications may be obtained from the Department of Militia and Defence, Ottawa. Eugene Fiset, Deputy Minister.

PATENTS.

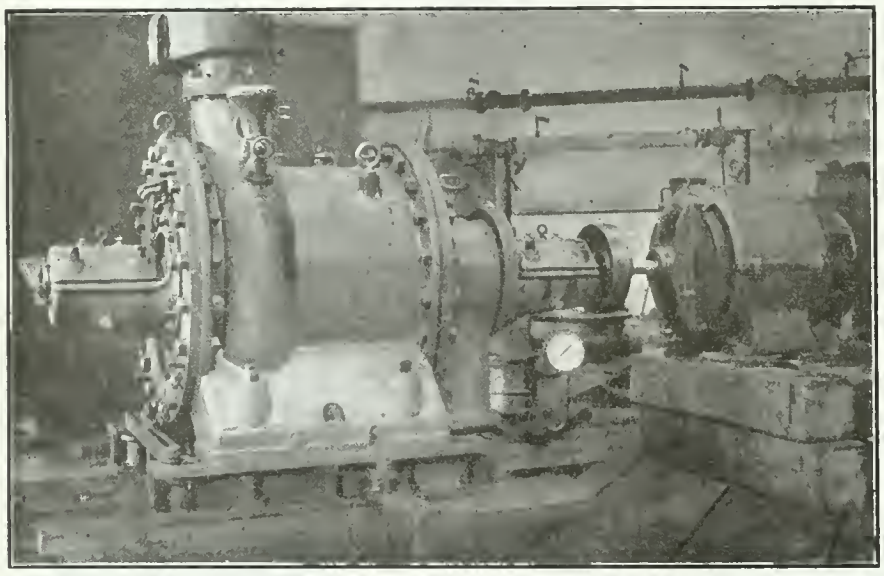
The following is a list of patents recently issued through the agency of Messrs. Ridout & Maybee, 59 Yonge Street, Toronto, from whom further particulars may be obtained:—

Canada.—Thos. Clarkson and W. J. Morrison, reducing valves; Alex. H. Welker, motor-winding mechanism; Thos. Clarkson and W. J. Morrison, metal wheels; Wm. Gibbs, disk-straightening and truing apparatus; John Fox, grain picklers; E. A. Bolton, steam superheaters; John C. Jackson, concrete poles; Thos. W. Brown, weather strips; Wm. P. Evans, shaft bearings; Lambertus Elfrink, fillers for caoutchouc and processes for manufacturing same; Geo. Cropper and H. E. Ritchie, suspension of motors and like road vehicles; Robt. McFarlane, windmills; Koolman and Ponndorf, hop-extracting apparatus; Harry Hudkins, plough trucks, and Woods, Gilbert and Little, dressing of stone.

United States.—Jethro Hoskyn, hammers.

Argentina.—Massey-Harris Company, Limited, harvesting machines.

Australia.—Fred. M. Bawdon, improvements in tire treads.



"BON-ACCORD" CENTRIFUGAL PUMPS

Illustration shows 12" pump designed for direct connection to a water-turbine running at comparatively low speed. It is consequently built with four stages. Photograph was taken in the testing bay. The normal speed for domestic supply is 520 r.p.m., when the pump delivers 1,100 Imperial gallons against 200 ft. head, requiring 92 h.p. When speeded up to 590 r.p.m. the pump gives a pressure of 260 ft., with the same quantity, for fire purposes, consuming 124 h.p.

MACK

What Motor Trucks will do for You

Would you like to know what motor trucks have done for other engineering and contracting concerns—how they use trucks?

What size and kind of body? What is the difference between motor-trucks and horse-drawn vehicles in the engineering and contracting business under exactly the same conditions?

7½ Ton Mack Automatic Dump Truck
used by the Metropolitan Coal Company for long distance heavy coal deliveries.

What the saving is in time and money, the increased area of business operations, etc.?

We shall be pleased to answer these questions for you and to furnish you data, without obligation on your part, showing what motor-trucks have done in your line.

We are Canadian Sales Agents for the Mack Truck manufactured by The International Motor Company.

MACK

"Leading Gasoline Truck of the World"

The first Mack Truck, built in 1900, is still in active service at Tucson, Arizona.

That fact should be full of meaning for you. In order for a truck to be profitable it must last long enough to pay back the original investment with a good big profit.

The Mack has proven its reliability, economy and long life by 12 years of real service in every line of transportation.

When you buy Mack Trucks you do not buy THEORY but HISTORY.

Mack Trucks are built in 1, 1½, 2, 3, 4, 5 and 7½ tons capacity, with any load distribution and any style of body.

Let us make an analysis of your requirements—what truck equipment, the cost, and what it would do for you.

TENDERS CALLED FOR

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

WELLAND SHIP CANAL.

SECTION No. 3.

NOTICE TO CONTRACTORS.

SEALED TENDERS, addressed to the undersigned and marked, "Tender for Section No. 3, Welland Ship Canal," will be received at this office, until 2 p.m., on **Wednesday, August 27th, 1913.**

Plans, specifications and form of contract to be entered into can be seen on or after this date at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Engineer in Charge, St. Catharines, Ontario.

Copies of plans and specifications may be obtained from the Department on the payment of the sum of fifty dollars. To bona fide tenderers this amount will be refunded upon the return of the above in good condition.

Parties tendering will be required to accept the fair wages schedule prepared or to be prepared by the Department of Labor, which schedule will form part of the contract.

Contractors are requested to bear in mind that tenders will not be considered unless made strictly in accordance with the printed forms, and in the case of firms, unless there are attached the actual signature, the nature of the occupation, and place of residence of each member of the firm.

An accepted bank cheque on a chartered bank of Canada, for the sum of $400,000.00, made payable to the order of the Minister of Railways and Canals, must accompany each tender, which sum will be forfeited if the party tendering declines entering into contract for the work at the rates stated in the offer submitted.

The cheque thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque of the successful tenderer will be held as security, or part security, for the due fulfilment of the contract to be entered into.

The lowest or any tender not necessarily accepted.

By order,
L. K. JONES,
Asst. Deputy Minister and Secretary.

Department of Railways and Canals,
Ottawa, 2nd August, 1913.

Newspapers inserting this advertisement without authority from the Department will not be paid for it.—46052.

CAYUGA, ONT.

Sealed tenders will be received up to noon on the 16th day of September, 1913, by the undersigned at Cayuga, Ontario, for the construction of twenty-six and one-half miles of stone macadam road in the county of Haldimand.

The work will be let in three separate and distinct contracts, not necessarily to the same individual.

Tenderers are required to examine the localities of the work and are requested to be present at the opening of the tenders at 2 p.m., on Wednesday, the 17th day of September, 1913.

Plans and specifications may be seen at the office of the County Engineers, Messrs. Jackson and Kyd, Dunnville, or may be had from them on the payment of $10, which sum will be refunded on return of the documents.

Lowest or any tender not necessarily accepted.

T. A. SNIDER, K.C.,
County Clerk,
County of Haldimand,
Cayuga, Ont.

THE COMMISSIONERS OF THE TRANSCONTINENTAL RAILWAY.

NOTICE TO CONTRACTORS.

TENDERS FOR LOCOMOTIVE AND CAR SHOPS AT ST. MALO, P.Q.

SEALED TENDERS addressed to the undersigned, and marked on the envelope, "Tender for Shops," will be received by the Commissioners of the Transcontinental Railway at Ottawa, Ontario, until 12 o'clock noon of **Tuesday, 2nd September, 1913,** for the construction and erection complete, in accordance with the plans and specifications of the Commissioners of a Locomotive and Car Shop repair plant at St. Malo, P.Q.

The plans, details and specifications, which will include the locomotive and car shops, the yard sewerage system and drainage system, yard water system, and the yard grading and track-laying, may be seen at the office of Mr. Gordon Grant, Chief Engineer, Ottawa, Ontario, and at the office of Mr. A. E. Doucet, District Engineer, Quebec, P.Q.

Persons tendering are hereby notified that tenders must be made on the printed forms supplied by the Commissioners. These may be had on application to Mr. W. J. Press, Mechanical Engineer, Ottawa, Ontario, or to Mr. A. E. Doucet, District Engineer, Quebec, P.Q.

Each tender must be signed and sealed by all parties to the tender, and witnessed, and be accompanied by an accepted cheque on a chartered bank of Canada, payable to the order of the Commissioners of the Transcontinental Railway for the sum of ($50,000.00) Fifty Thousand Dollars.

The cheque received from the party whose tender is accepted will be deposited to the credit of the Receiver-General of Canada, as security for the due and faithful performance of the contract, according to its terms.

Cheques received from parties whose tenders are rejected will be returned within ten days after the signing of the contract.

The right is reserved to reject any or all tenders.

By order,
P. E. RYAN,
Secretary.

The Commissioners of the
Transcontinental Railway.
Dated at Ottawa, Ont., July 28th, 1913.

Newspaper inserting this advertisement without authority from the Commissioners will not be paid for it.—45825.

MAIN DRAINAGE WORKS.

Sealed tenders addressed to the Chairman of the Board of Control, City Hall, Toronto, will be received by registered post only, up to noon of Tuesday, August 26th, 1913, for the supply and erection of three motor-driven Centrifugal Sewage Pumps, automatically controlled.

Plans, specifications, forms of tender and other information may be obtained at the office of the Commissioner of Works, City Hall, Toronto.

H. C. HOCKEN (Mayor),
Chairman, Board of Control.

City Hall, August 9th, 1913.

(For further Tenders see page 86.)

Consider the Cost

of always paying high insurance rates—of always running the risk of your business being stopped by disastrous fires—of always feeling the dread of possible fatal consequences to your employees should a fire suddenly occur.

The time to consider is before you build—before the plans are finished. We have a staff of engineers and inspectors who are specialists in fire-proof construction and insurance ratings. Without charge we will place our highly specialized knowledge of these matters at your, or your engineer's or architect's disposal. Our brokerage department will then be able to obtain for your structure the lowest possible insurance rate.

TENDERS CALLED FOR

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

TRENT CANAL.

PORT SEVERN SECTION—SEVERN DIVISION.

NOTICE TO CONTRACTORS.

SEALED TENDERS, addressed to the undersigned and marked, "Tender for Port Severn Section—Severn Division, Trent Canal," will be received at this office until 2.00 o'clock p.m., on **Monday, August 25th, 1913.**

Plans, specifications and form of contract to be entered into can be seen on or after July 26th at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa; at the office of the Superintending Engineer, Trent Canal, Peterborough, Ont.; at the office of the District Engineer, Public Works Department, Midland, Ont., and at the office of the Postmaster, Orillia, Ont.

Parties tendering will be required to accept the fair wages schedule prepared or to be prepared by the Department of Labour, which schedule will form part of the contract.

Contractors are requested to bear in mind that tenders will not be considered unless made strictly in accordance with the printed forms, and in the case of firms, unless there are attached the actual signature, the nature of the occupation, and place of residence of each member of the firm.

An accepted bank cheque on a chartered Bank of Canada, for the sum of $10,000, made payable to the order of the Minister of Railways and Canals, must accompany each tender, which sum will be forfeited if the party tendering declines entering into contract for the work, at the rates stated in the offer submitted.

The cheque thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque of the successful tenderer will be held as security, or part security, for the due fulfilment of the contract to be entered into.

The lowest or any tender not necessarily accepted.

By order,
L. K. JONES,
Asst. Deputy Minister and Secretary.

Department of Railways and Canals,
Ottawa, 29th July, 1913.

Newspapers inserting this advertisement without authority from the Department will not be paid for it.—45677.

SEALED TENDERS addressed to the undersigned, and endorsed, "Tender for East Pier, Eastern Entrance, Toronto Harbour, Ont.," will be received at this office until 4.00 p.m., on **Tuesday, September 2nd, 1913,** for the reconstruction of part of superstructure of East Pier of Eastern Entrance to Toronto Harbour, in the County of York and Province of Ontario.

Plans, specification and form of contract can be seen and forms of tender obtained at this Department and at the offices of J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto, Ont., and H. J. Lamb, Esq., District Engineer, Windsor, Ont.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honourable the Minister of Public Works, equal to ten per cent. (10 p.c.) of the amount of the tender, which will be forfeited if the person tendering declines to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, August 1, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—43525.

(For further tenders see page 84).

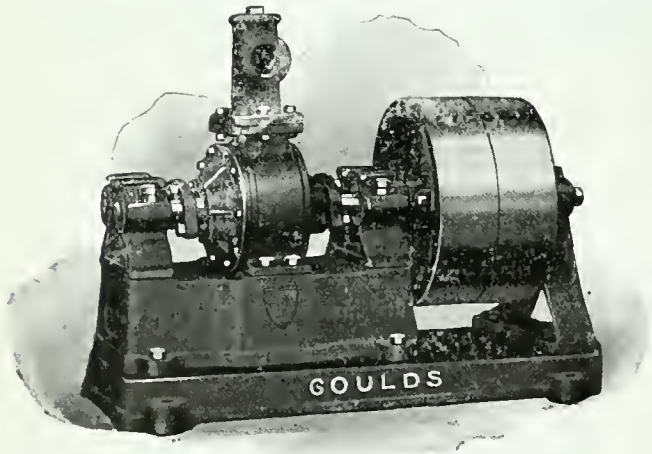
TRADE ENQUIRIES.

The following inquiries relating to Canadian trade were received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W.: A Vancouver firm desire to dispose of a modern stiff-mud shale brick plant and a 50-acre shale deposit near Vancouver, and invite inquiries from interested parties in Great Britain.

NEW ROTARY POWER PUMP.

A new type of rotary power pump has just been developed by the Goulds Manufacturing Company, Seneca Falls, N.Y., This pump differs from the rest of the line of pumps of the same capacity in that gear-style cams have been substituted

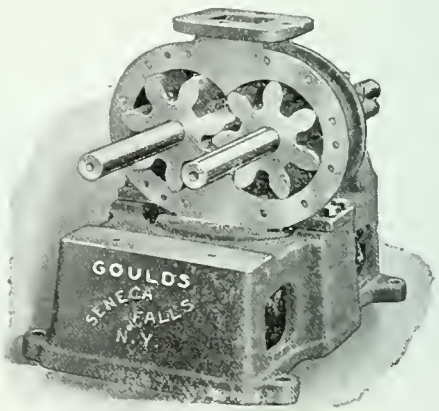


The Goulds Rotary Pump.

for the three-toed cams used in the remainder of the line (as shown by one of the illustrations), and the gears on the end of the cam shafts have been eliminated.

Two sizes are built. No. 1 has a capacity of 25 to 50 gallons per minute at 225 to 450 revolutions, and No. 2 has a capacity of 50 to 100 gallons per minute at 225 to 450 revolutions. Both pumps are suitable for pressures up to 100 pounds, or 230 feet elevation.

They are mounted on a cast-iron bedplate, fitted with an outboard bearing and tight and loose pulleys for belt-drive. The suction connection is made within the base, directly beneath the case, and is reached through hand-holes in the base. No. 1 has two discharge openings, one tapped for



Section Showing Unique Design of this New Type.

pipe and the other threaded for hose couplings. No. 2 has three discharge openings, two fitted the same as No. 1, and the third fitted with an interchangeable blank flange.

The suction is 3-inch on No. 1 and 4-inch on No. 2. The discharges are for 1½ and 2-inch pipe or hose, respectively.

The Goulds line of pumps are for sale in Canada by the Canadian Fairbanks-Morse Company, Limited.

PATENT NOTICE.—Notice is hereby given in regard to Canadian patents 100,707, 100,980 and 129,756, steam turbines, and 135,000, 135,001, 136,321 and 137,222, classifiers, that Canadian Allis-Chalmers, Limited, Toronto, owner of rights under said patents, is prepared to supply devices covered by these patents.

NOTICE.—Any one desiring to obtain the invention covered by Canadian patent No. 134660, granted on October 8th, 1911, to Jules Blanc, for process and apparatus for destroying rats by purified sulphur dioxide, may do so upon application to the undersigned who are prepared to supply all reasonable demands on the part of the public for the invention, and from whom full information may be obtained. Fetherstonhaugh and Smart, Castle Building, 53 Queen Street, Ottawa; Russel S. Smart, resident.

NOTICE.—Any one desiring to obtain the invention covered by Canadian patent No. 127846, granted on August 30th, 1910, to Alexander Albert Holle, for fluid turbines, may do so upon application to the undersigned who are prepared to supply all reasonable demands on the part of the public for the invention, and from whom full information may be obtained. Fetherstonhaugh and Smart, Castle Building, 53 Queen Street, Ottawa; Russel S. Smart, resident.

HAYES' DERAILS

Derailing devices and operating mechanisms for derails made according to the well-known HAYES' designs.

The undersigned are prepared to furnish the above devices at moderate cost under Canadian Letters Patent 106,831 and 106,832.

All communications regarding these should be addressed to

Canadian Hart Wheels Limited,
HAMILTON, ONT.

NEW INCORPORATIONS.

Berlin, Ont.—Berlin Industrial Centre, $40,000. A. Millar, H. J. Sims, W. H. Gregory.

Sarnia, Ont.—Harrow Canners, $40,000. A. T. Gahan, M. E. Oxenham, N. L. LeSoeur.

Tillsonburg, Ont.—Universal Paint and Varnish Remover Company, $50,000. J. H. Teall, G. W. Tillson, W. H. Bennett.

Elora, Ont.—John C. Mundell and Company, $300,000 (furniture dealers). J. C. Mundell, J. A. Mundell, both of Elora, J. S. Allan, Guelph.

Hamilton, Ont.—Saskatchewan Farm Land and Development Company, $250,000. C. W. Linnenbank, L. Bercowitz, C. S. Walters. Goodwin Park, $40,000. G. W. Tinlin, F. H. Jory, G. A. Tinlin. Hamilton Tailors, $40,000. M. Silverman, S. C. Harris, L. Silverman. Strathearn Park, $40,000. J. B. Weir, A. B. Crearer, Mrs. E. M. Weir.

MARKET CONDITIONS

Montreal, August 9th, 1913.

Bar Iron and Steel.—Trade is reported active. Bar iron, $2.10 per 100 pounds; best refined horseshoe, $2.35; forged iron, $2.25; mild steel, $2.20; sleigh shoe steel, $2.20 for 1 x ¼ base; tire steel, $2.30 for 1 x ¼ base; toe caulk steel, $3; machine steel, iron finish, $2.25.

Cement.—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1.40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re-purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain.—The market is unchanged, being now per 100 lbs., as follows:—¼-in., $5.30; 5-16-in., $4.70; ⅜-in., $3.90; 7-16-in., $3.65; ½-in., $3.55; 9-16-in., $3.45; ⅝-in., $3.40; ¾-in., $3.35; ⅞-in., $3.35; 1-in., $3.35.

Explosives and Accessories.—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron.—The market is steady. Prices, basis, 28-gauge, are: Queen's Head, $4.35; Colborne Crown, $4.25; Apollo, 10¼ oz., $4.25. Add 25c. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¼ oz., and English 28-gauge.

Galvanized Pipe.—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $22.50 per ton; selected Summerlee, $22; soft Summerlee, $21.50 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron, number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19.25 to $19.50 per ton, on track.

Lath.—See Lumber, etc.

Lumber, Etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph Poles: seven-inch top, cedar poles, 25-ft. poles, $2 each; 30-ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce, 4-ft x 1½-in., mill run, $3 to $3.25; pine, 4-ft. x 1½-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2.10; XX, $2.40; XXX,, $2.80.

Pipe.—Cast Iron.—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 4o-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe.—Wrought and Galvanized.—Demand is fair and the market steady:—¼-inch, $5.50, with 64 per cent. off for black, and 49 per cent. off for galvanized; ⅜-inch, $5.50, with 64 per cent. off for black, and 49 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent. off for black, and 59 per cent. off for galvanized. The discount on the following is 73½ per cent. off for black, and 63½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 73½ per cent. for black and 63½ per cent. for galvanized:—2-in., $36; 2½-in., $57.50, and 3-in., $75.50; 73½ per cent. off for black, and 63½ per cent. off for galvanized; 3½-inch., $95; 4-inch, $1.08.

Toronto, August 13th, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double hitted, $6 to $10; single hitted, per dozen, $7.50 to $9.

Bar Iron.—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel.—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates.—¼-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes.—Orders continue active. Lap-welded, steel, 1¼-inch, 10c.; 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Brick.—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $13 to $15 per M., three grades.

Broken Stone.—Lime stone, good hard, for roadways or concrete, f.o.h., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto, 60 cents.

Cement.—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot.—The market is lower at 15½ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps.—75c. and $1 per 100; case lots, 5,0000, 20 per cent. off.

Dynamite.—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¼ cents pound, 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1½c. per hundred. For 10-case lots and over deduct ½ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1½ cent.

Fuses.—Electric Blasting.—Double strength, $3.50 per hundred, advance 5c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 5c. per hundred for each 2-in. wire additional.

Iron Chain.—¼-inch, $5.75; 5-16-in, $5.15; ⅜-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3.55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe.—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.34; 1¼-inch, $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40.60; 6-inch, $52.64. Galvanied Pipe, ¼-inch, $2.86; ⅜-inch, $2.86 ½-inch, $3.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead.—Firmer, $5.25 to $5.50.

Pig Iron.—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar.—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate.—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green, $8, with a prospect of advance. Dealers are fairly busy.

Sand.—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe.—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0.25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00
Double junctions	1.25	2.00	3.25	5.00	16.25
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. H. traps	2.00	3.20	6.50	13.00	.....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes, 9 inches and under or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels.—Active.—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2.75 to $3 per 100 pounds. Extra for smaller sizes of angles and tees.

Sheet Copper.—22c. per lb.

Sheet Steel.—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized.—Apollo Brand.—Sheets, 6 or 8 feet long, 30 or 36 inches wide; 10-gauge, $3.00; 12-14-gauge, $3.00; 16, 18, 20, $3.30; 22-24, $3.40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 pounds. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin.—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel.—Jowett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates.—3-16-inch, $2.40 per 100 lbs.

Zinc.—Spelter.—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, August 12th, 1913.

Anvils.—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¼ to 10¾c.; anvil and vise combined, each $5.50.

Bar Iron.—$2.50 base.

Bars.—Crow, $4.50 per 100 pounds.

Beams and Channels.—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick.—Kiln run per M, $13; sewer per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland.—$2.40 to $2.50 per barrel.

Chain.—Coil, 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7-16, $4.75; ½, $4.50; 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5¾c. Tie out, 70 and 10 per cent.

Copper.—Tinned, boiler, 26½c., planished 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent discount.

Dynamite.—$11 to $13 per case.

Galvanized Iron.—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20, $4; 18, $3.95; 16, $3.90; Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30; 22, $4.30; 20, $4.10 per cwt.

Iron.—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26-gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American, $5.15; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe.—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7.80; 1½-inch, $9.35; 2-inch, $12.50; galvanized—½-inch, $4.35; ¾-inch, $5.20; 1-inch, $7.35; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch.—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled.—3-16-in., $3.35 base; machinery, $3 base; share, $4.50 base; share crucible, $5.50, cast share steel, $7.50; toe calk, $4.50 base; tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel.—8½ to 15c. per pound.

The Canadian Engineer

A weekly paper for engineers and engineering-contractors

THE NEW WELLAND SHIP CANAL

THE THIRD AND GREATEST WATERWAY TO JOIN LAKES ERIE AND ONTARIO—ITS GENERAL DESIGN AND COURSE—HISTORICAL NOTES RELATING TO OLD WELLAND CANALS.

AMONG the big engineering undertakings started during the present season there are few that excel in size the structure which is to replace the canal which connects Lakes Erie and Ontario. The Welland Canal now in use has, since its construction, been known as the "new" canal, in distinction from the original waterway which is now historically referred to as the "old" canal, the work under contemplation therefore constituting the third. The original and present canals followed a route from Port Colborne across the Niagara peninsula, practically paralleling each other at the northern end, entering Lake Ontario at Port Dalhousie. The original canal was commenced in 1824, and completed in 1833, the line following very closely certain water courses, to facilitate construction, making the length 27½ miles. This canal contained 27 locks, 24 of which were 150 by 26½ ft., and the other three, 200, 230 and 270 by 45 ft., respectively. The depth of water on the sills was 10¼ ft., with a total lift of 326¾ ft. The initial construction of these locks gave a depth of 8 ft., the increase of 10¼ ft. being a subsequent change. The present canal was commenced in 1872, and completed in 1887. The route at the northerly end was slightly changed to the east near St. Catharines, the canal coming out into Lake Ontario at the same point as the original one. The locks are 26 in number, 270 by 45 ft., with a depth of 14 ft. over the sills.

The route to be followed by the proposed canal, beginning at the southern terminus, i.e., at Port Colborne, is the same as that of the present canal as far as Thorold, from which point it will deviate to connect with a harbor which will be constructed at the Lake Ontario end, some three miles east of the present Port Dalhousie outlet, this diverging portion being about eight miles in length, and passing in almost a straight line through Merritton to the lake. The section of the existing canal between Thorold and Merritton will, therefore, be abandoned, but it is the intention to use the portion of the present canal between that point and Port Dalhousie as an auxiliary.

The present canal is made up of twenty-five locks each 270 ft. by 45 ft. with some 14 ft. of water over the sills. The total length of this canal is 26¾ miles.

The new canal will have seven locks each of 42½ ft. lift, 80 ft. width, and sufficiently long to accommodate a vessel of the length of 800 ft. It will be 25 miles from lake to lake and will cope with a difference of level of 325½ ft. between them. The minimum depth of water over the miter sills of each lock will be 30 ft. The bottom of the canal will be 200 ft. in width, and although the depth will ultimately reach 30 ft., the present excavation will stop when 25 ft. is reached, further deepening being looked after when occasion arises by dredging out the reaches to the required depth, according to design The lock walls will be 82 ft. high above the top of the gate sills, and including the necessary foundation work required below this level two of the locks will have walls 100 ft. high. The lock gates will be of the single-leaf type, swinging on a hinge at one side of the lock and resting in a notch cut in the opposite wall, a single leaf thus spanning the whole width of the lock chamber. The gate at the foot of each lock will be 83 ft. high and 88 ft. long, and will weigh about 1,100 tons. The valves and culverts in the walls will be of large dimensions and will permit of the lock being filled in less than eight minutes. This will mean that the time of passage through the canal will be reduced much below that required at present. The time of lockage of the present canal is from 10 to 20 minutes per lock. In the new canal there will be 18 fewer locks, and the saving in locking time will be in the neighborhood of three hours.

Port Colborne Development.

In Fig. 1 will be noted a proposed new breakwater off Port Colborne, to prevent a disturbance of harbor water, with which the present conditions have to contend, as the present breakwater is insufficient in effect owing to size and location. The new breakwater will consist of an immense rubble mound of stone from the excavation north of Port Colborne, and will terminate in a timber-and-concrete headblock located some 2,000 ft. farther out in the lake than the present breakwater.

The outer harbor at Port Colborne has now a 22-ft. depth of water at ordinary stages of the lake, which is as much as is available at most of the other lake ports and in the channels connecting the lakes at the present time. The deepening of this portion of the harbor may be left for a few years until the connecting channels in the lakes allow deeper navigation. The inner harbor will be excavated to the new depth proposed, and the old locks and regulating weir now in the centre of the village will be entirely removed.

From Port Colborne to Humberstone the rock cut will be deepened and widened on the west side, and just below Humberstone a new cut will be made across the

point now forming Ramey's Bend, materially straightening the canal. The excavation from this cut will be principally rock, and will form suitable material for the breakwater in Port Colborne harbor.

A guard lock will be built in the rock cutting a short distance below Humberstone, and when this new cutting is ready for navigation a regulating weir will be built across the abandoned portion of the present canal, which will be used as a by-pass to furnish water to the canal. This lock and regulating weir will control the elevation of the summit level of the canal, which it is proposed to keep at the level of extreme low water in Lake Erie, viz., 568 ft. above sea level.

The Welland River Crossing.

From Ramey's Bend to Welland the present canal will be enlarged by an extended excavation along the western bank. It crosses the Welland River by an aqueduct at Welland, as indicated in Fig. 1, but in the new structure it is proposed to raise the level of the river to that of the summit level of the canal by means of a dam across the river at Port Robinson. This dam will be provided with a large overflow and regulating weir, which will control the elevation of the summit level, allowing any surplus water to overflow into the old Welland River and pass out into the Niagara River at Chippawa, as at present. A sufficient quantity of water will be allowed to run constantly to keep the river clean.

The present aqueduct at Welland will be dredged out, as well as the bank between the canal and the river. The river will be utilized between Welland and Port Robinson instead of the present canal, being somewhat more direct and entailing considerably less excavation. At Port Robinson a cut will be made through the present bank between the canal and the river, enabling vessels to re-enter the canal prism. Between Port Robinson and Allanburg what is known as the "Deep Cut," which has a maximum depth of 66 ft., will be enlarged by cutting a slice off the western bank.

In raising the Welland River above Welland some 1,600 acres of low land adjoining the river will be flooded. This land is not of any great value, as it is flooded every spring by the river overflow, limiting its agricultural value to pasturage only. The township of Wainfleet, adjoining the Welland River on the south side, consists principally of low-lying ground which drains into the Welland River, and to prevent damage to this land on account of the raising of the river it will be necessary to open up most of the ditches from the point of their present entrance to the river, to the intended high-water mark.

Turning the Welland River into the canal will pollute the waters which are at present used by the towns of Welland, Thorold and Merritton and the city of St. Catharines for domestic purposes. This may necessitate the construction of extensive filtering plants, although

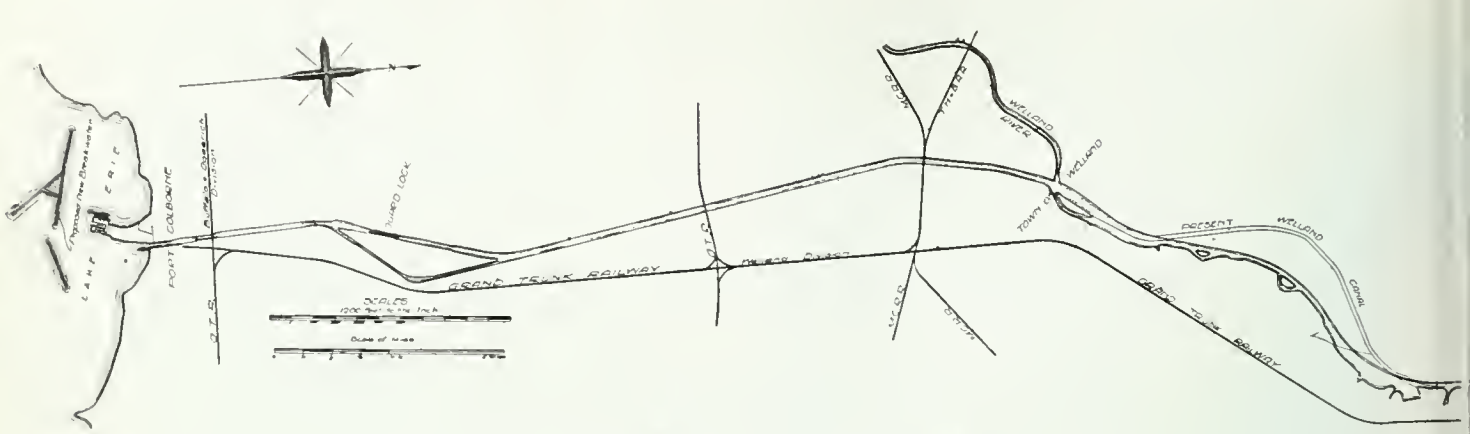

Fig. 1.—Course of New Welland Ship Canal, 25 Miles in Length.

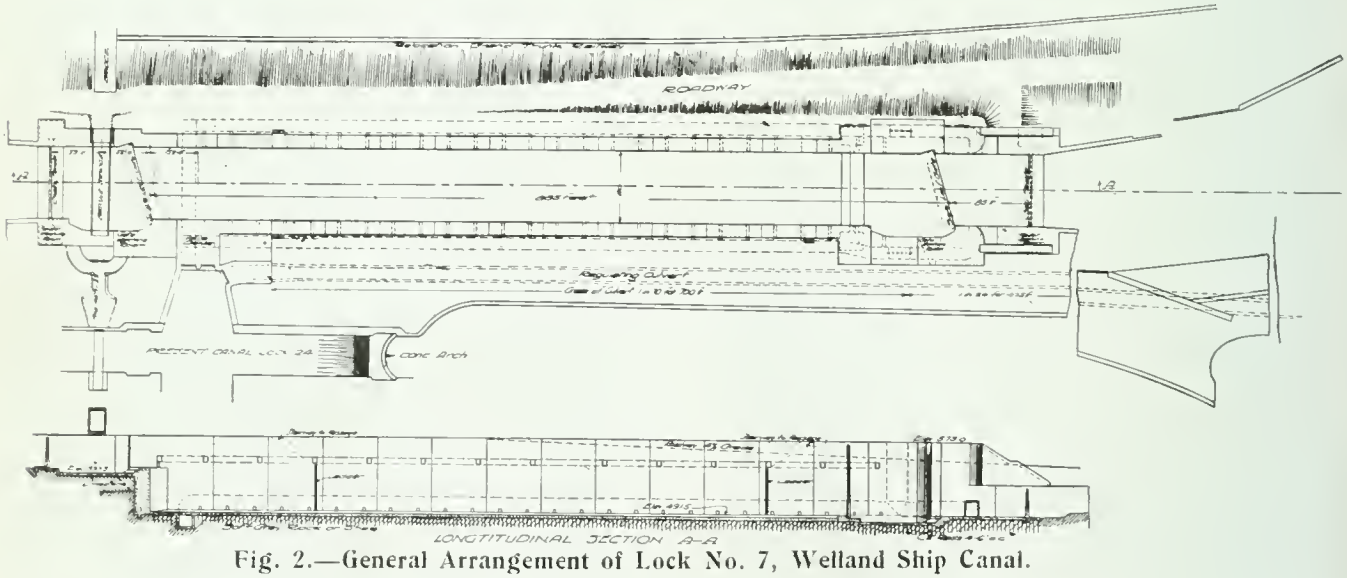

Fig. 2.—General Arrangement of Lock No. 7, Welland Ship Canal.

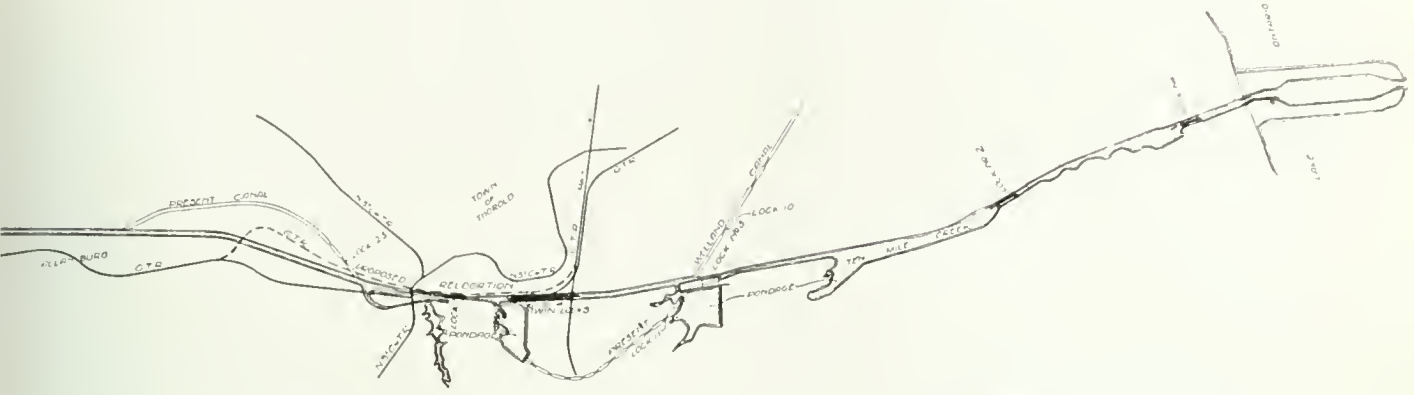
this scheme is not looked upon with favor by those interested. An alternative scheme to lay a pipe line from Lake Erie to the reservoirs of the different municipalities, through which clean water would be continuously pumped, is under consideration and appears to be the most feasible scheme available.

Allanburg is now the junction of the present and old

dumping ground, and the old canal will become more self-contained, as at present the entrance works are situated at an inconvenient distance from the remainder of the canal.

If it is desired to continue navigation on the old canal, entrance may be had to it through lock 25 of the present canal (a little south of the town of Thorold) when



It is Equipped With Seven Lift Locks, Each 800 Feet in Length, With 46½ Feet Lift.

Welland Canals, and the water required for the latter, which is quite considerable, on account of the numerous power developments along it, is taken into the canal through a weir at this point.

In connection with the construction of the new canal, it is proposed to close the present old canal entirely between Allanburg and Marlatt's Bridge, near Thorold, first building a new weir at the head of lock 25 of the present canal, to supply the above mentioned water. A dam will then be thrown across the old canal at Allanburg, and the old bed of the canal between the dam and Marlatt's Bridge will be utilized as a dumping ground in which to place the material removed from the above water in widening the deep cut. This will form a very convenient

the new canal is completed, by making a short cut through the bank separating the two waterways.

New Lock No. 7.

Between this point and Thorold will be located a pair of twin guard locks, just at the southerly limits of the town, and a short distance north of them will be located lock 7, the head of this lock being directly opposite the head of lock 24 on the present canal. Fig. 2 shows its general design. The portion of the present canal between locks 25 and 24, together with a pond of about 27 acres, formed by flooding the upper valley of the Ten Mile Creek, will be utilized as a regulating basin from which water to fill lock 7 will be drawn. This method of drawing water from a side pond, instead of directly from the canal above, avoids the formation of objectionable currents and surges in the canal and locks, and is the method adopted for filling all of the locks.

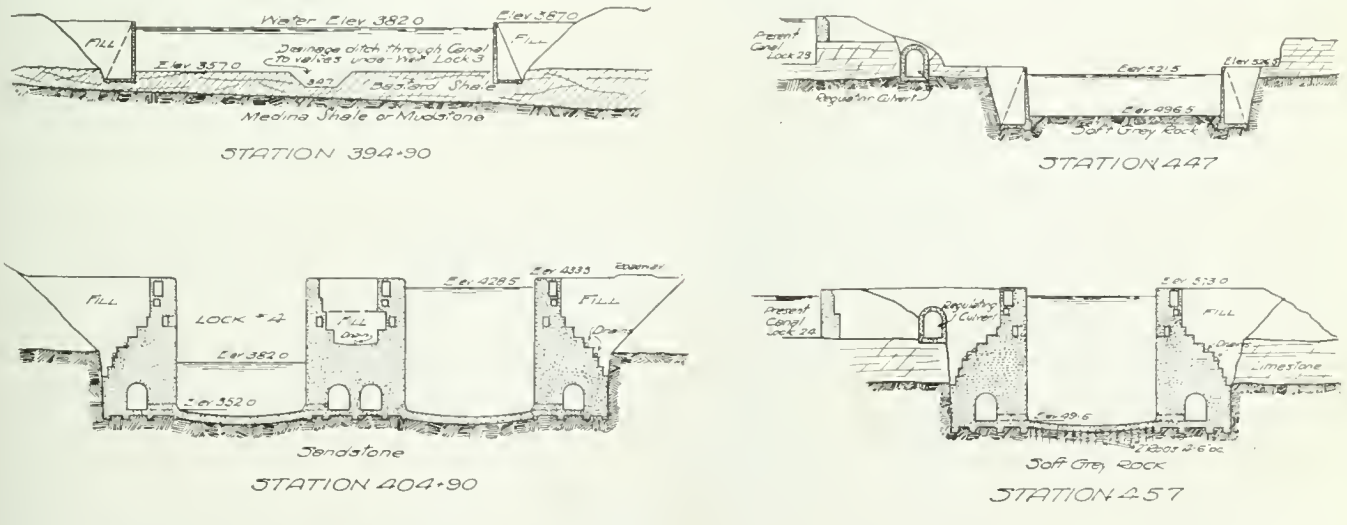


Fig. 3.—Typical Cross-Section of Earth-Works at Various Points.

Below lock 7 will be a short reach of canal, with an adjacent pondage or regulating basin having a surface

area of about 84 acres (see Fig. 1), and immediately below will be located twin locks 6, 5 and 4 in flight. These three locks will overcome a descent of 139½ ft. One flight will be used for down bound vessels and the adjoining flight for up bound, a double flight being required to save long delays in the passage of vessels through the canal.

The main line of the G.T.R. between St. Catharines and Niagara Falls will cross over the foot of twin locks 4, by means of two short bascule lift bridges.

The Port Dalhousie-Welland branch of the G.T.R. is situated just where the new locks are to be built, and it will be necessary to divert it some distance to the west. The diverted line will bear the same relation to the new canal as the present line does to the present canal, following upon the west side of the locks, but remaining on the west side of the canal for some distance above the present lock 25, when it will cross the new canal by means of a bascule lift bridge.

From lock 4 the proposed waterway will run northwards, following in part the bed of the Ten Mile Creek until it crosses the present canal at the foot of lock 11, at an elevation of 382 ft. above sea level. This is the level of the present canal at that point, and small vessels may, if desired, use the Port Dalhousie entrance, as at present, as far as lock 11. (See Fig. 1.)

Lock 3 will be located immediately north of the present canal, and at its head on the east side will be situated an equalizing basin or pondage with an area of 150 acres. Below lock 3 a heavy cut will be required through the village of Homer to a point where the bed of Ten Mile Creek is again reached, and below this point lock 2 will be built, as shown. It was difficult to find a location for this lock on account of the lack of rock for a foundation, but eventually a suitable foundation was found at this site. The canal at the head of lock 2 will be at an elevation of 335½ ft. above sea level and will flood about 200 acres of land along Ten Mile Creek. Below lock 2 the canal will follow the bed of the creek to the lake, lock 1 being situated just below the Lake Road. The pond at the head of lock 1 will cover an area of 107 acres.

Some typical cross-sections of several locks are shown in Fig. 3.

The Entrance Into Lake Ontario.

The outer entrance piers in Lake Ontario will be placed about a mile and a half from shore, where the depth of water is 30 ft. A wide channel will be dredged from these piers to lock 1. The sides of this channel will be protected near the shore end by reinforced concrete cribs, with concrete superstructures, alongside which vessels may lie. This arrangement is illustrated in Fig. 1. From the shore line of the lake to the outer entrance piers an embankment about 500 ft. wide will be formed on either side of the channel, from material excavated from the canal between the lake and Thorold. For the purpose of conveying this material from the different contracts to the lake, the Department of Railways and Canals will build a double track railway along the west side of the canal from the foot of the flight locks near Merritton to the lake, and temporary trestles will be built out in the lake on either side of the harbor, from which to start the dumps. The railway will also be utilized to haul crushed stone from the site of the flight locks to locks 1, 2 and 3, for making concrete. The contractor for the rock excavation from the site of the flight locks will, under his contract, be obliged to crush a sufficient quantity of the good rock taken from his excavation to supply all the crushed stone required for making all the concrete for the different locks and structures.

The construction of the new canal is under the direction of the Department of Railways and Canals. It will cost approximately fifty million dollars. The engineer in charge of the entire construction is Mr. J. L. Weller, M. Can. Soc. C.E.

The contract for the first section of the work, a length of about three miles, including lock 1, and the pier works at the Lake Ontario entrance, was awarded early in July to the Dominion Dredging Company, Limited, Ottawa, the contract price being about $3,500,000. Other sections are following closely, and contracts for them will be awarded before the close of August.

MONEL METAL.

A synopsis is given by R. H. Gaines in Chemical News, of the methods of manufacture of this new alloy, the reduction of which has now been so perfected as to give a product of very uniform composition, different analyses of different varieties only varying betyeen the limits: Nickel, 67.55 to 69.54 per cent.; copper, 26.25 to 27.53 per cent.; carbon, 0.17 to 0.44 per cent., and iron, 2.07 to 3.33 per cent. In forged or rolled metal the manganese varies from 1.26 to 1.82 per cent., and the silicon from 0 to 0.37 per cent., while in cast metal the manganese varies from 0.09 to 0.49 per cent., and the silicon from 1.08 to 1.41 per cent. Variations in mechanical properties have little relation to variations in composition. Carbon appears to strengthen the alloy; iron hardens, whitens, and increases the strength, but appears to reduce the elastic limit. Silicon and manganese do not materially affect the physical properties, but manganese may correct the action of sulphur, which is probably present. The alloy resembles nickel in color, it machines well, and takes a high polish and retains it indefinitely. It melts at 1,360° C.; has a specific gravity of 8.87 and a hardness number of 20 to 27 on the Shore scale. It is magnetic and absorbs carbon, which can exist in it both free and combined. Compared with nickel and copper its mechanical properties are:—

	Copper, rolled.	Nikel, rolled.	Monel metal. Cast.	Rolled.	Annealed.
Tensile strength, pounds per square inch	34,000	75,500	85,000	100,000	110,000
Elastic limit, pounds per square inch	18,000	21,000	40,000	50,000	80,000
Elongation, per cent. in 2 inches	52	43.9	25	30	25
Contraction, per cent.	57	57	25	50	50
Modulus of elasticity.	....	.....	22,000,000 to 23,000,000		

Monel metal resists corrosion by sea-water, superheated steam, and chemical solutions about as well as Parson's manganese bronze, phosphor bronze, and Tobin bronze. There is no difficulty in forging and rolling it, but on account of its high melting-point and power of dissolving gases special precautions are needed in making sand castings, somewhat similar to those necessary for making steel castings. These uses are suggested: pump cylinders for sea-water, propellers, rudders, mining screens, valves, and plumbing fixtures subject to corrosive influences. Sheets of monel metal are largely used in America for roofing purposes.

THE DETERMINATION OF INTERNAL TEMPERATURE RANGE IN CONCRETE ARCH BRIDGES

BULLETIN No. 30 of the Iowa State College, engineering experiment station, contains a treatment of this subject by Messrs. C. S. Nichols, assistant director of the station, and C. B. McCullough, assistant engineer, Iowa Highway Commission. The experimental data from which their conclusions were deduced, relates to observations on a number of concrete structures, taken by themselves and others during the past four years. The report contains the results in detail, while only the introduction and the conclusions arrived at are published herein.

The use of the arch in bridge construction dates back over two thousand years, although it was not until the latter part of the nineteenth century that reinforced concrete was used for such structures. The invention of this type of construction is generally conceded to Joseph Monier, of Paris, the date of the building of his first arch bridge usually being given as 1867. In the year 1894 F. Von Emperger introduced the "Melan" system of reinforced concrete arch construction into this country, and built the first reinforced concrete bridges of considerable span. Edwin Thatcher was also a pioneer in this work, building bridges as early as this date.

While it is thus seen that the use of reinforced concrete in arch bridges is of comparatively recent date, yet the growing sentiment in favor of it, because of its peculiar esthetic value, is so great as to warrant the belief that this type of structure as a highway bridge will not be replaced by staticly determinate structures, at least not within the lifetime of the present generation of bridge builders.

One of the main arguments used against the adoption of this type of construction is our present limited knowledge of the actual internal forces for which the structure should be designed. Particularly is this true of the range of internal temperature. The immediate necessity for an investigation of this temperature range in arch bridges was therefore manifested in two ways:

(1) There is at present a very great diversity of practice among our western bridge companies in allowing for internal temperature variation in their arch bridge design. It has been ascertained, from good authority, that several of the prominent construction companies of the West are designing their structures to withstand temperature variations of from 15 degrees to 30 degrees F. each way from normal. Others are allowing a fixed percentage of the dead load stresses, this generally being, in highway construction, from 10% to 20 %, while analysis according to the elastic theory for the range to be expected in this latitude gave temperature stresses (in the case of one arch) as high as 206% of the dead load stresses at the crown, and 123% of the dead load stresses at the spring time.

One of the prominent concrete engineers of the east wrote: "We allow, in this latitude, (New York) or anywhere in the northern states, a range of 40 degrees in temperature, or 20 degrees each way from the mean. This may or may not be sufficient."

(2) There are scarcely any available experimental data on the range of temperature in concrete having a direct bearing upon the design of reinforced concrete arch bridges. The replies to a large number of letters sent out prior to the beginning of the tests, brought out very strikingly the fact that, while there were considerable available data and many theories concerning the expansion and contraction in concrete, yet very little was known concerning the actual internal variation of temperature in concrete structures.

Conclusions.—From the results, the writers draw the following conclusions:

I. The yearly range in temperature in a reinforced concrete arch structure, typical of the highway arch construction in this State, is, in this latitude, not far from 80 degrees F.

II. The relation between the depth of concrete covering at any point and the yearly temperature range may be obtained from a curve plotted from the results obtained on bridges under test. The curve that most nearly passes through the centre of the results can be represented by the equation

$$y = 90 - \frac{53}{100} x$$

wherein y = the yearly temperature range in degrees Fahrenheit, and

x = the distance from the nearest exposed surface in inches.

However, the effect of the different factors, such as the presence of a water surface, direction of prevailing winds, etc., so modify the results that the writers prefer to state their conclusions as in I., giving an average value for points throughout a structure of this type.

III. The amount of direct sunlight modifies somewhat the actual temperature in the concrete for a considerable distance into the interior of the mass, although, on account of the meagre nature of the data gathered, no definite conclusion can be stated.

IV. The data seem to show that in structures of this type the minimum temperatures are attained in time intervals anywhere from less than one day to four days after the atmospheric minimum. This interval depends upon the position of the portion of the structure considered, and is roughly proportional to the distance from the nearest exposed face.

V. Because of the high temperature in the concrete when it attains its set, and the effect of atmospheric temperature upon this maximum, other conditions being equal, the pouring of an arch ring at a temperature near the atmospheric mean annual operates to materially lower the stresses in the ring induced by temperature variation.

VI. When uninfluenced by other factors than atmospheric variation, the rise and fall of an arch ring agree quite closely with theory.

VII. The shrinkage of concrete, if unrestrained by reinforcing, amounts, in 100 days after placing, to about 4/1000 per cent. This induces bending stresses analogous to those produced by a temperature drop, but these are so modified by the initial stresses due to shrinkage that the chief effect is to cause a high compression in the steel on the compression side of the bending. When, due to other forces acting on the structure, a high compressive stress in the steel is encountered, the effect of this shrinkage should be carefully studied.

VIII. To render an arch ring structurally safe, provision should be made, in this latitude (Iowa) for stresses induced by a temperature variation of at least 40 degrees F. each way from an assumed temperature of no stress. Particular circumstances may demand that a greater variation be used for drop in temperature to prevent the appearance of cracks. This will always remain largely a matter of judgment with the designing engineer.

A MAINTENANCE-OF-WAY DEPARTMENT RAILROAD TESTING PLANT.*

By B. B. Milner.

SOME time ago the writer was asked to assist a maintenance-of-way engineer in the investigation of a problem which involved a study of track design and the stresses imposed upon its various members. Consultation with several men of recognized experience and authority, as well as an investigation of all experimental work performed in this connection, and a search through the literature of the subject, revealed the fact that dependable data upon which to base definite conclusions upon various points raised were lacking.

The same revelation was made by Mr. O. E. Selby, bridge engineer of the Cleveland, Cincinnati, Chicago & St. Louis Railway, in a paper, entitled "A Study of the Stresses Existing in Track Superstructure and Rational Design Based Thereon," which was published in Bulletin No. 80, American Railway Engineering and Maintenance-of-Way Association, October, 1906. This paper elaborated upon the statement that "railroad track has grown in strength as heavier loads have made increased strength necessary, but such growth has been entirely along empirical lines, and not one single detail of track superstructure bears marks of engineering design."

Mr. Selby, after careful consideration of such factors as rail loading and stress therein, tie bending, bearing of tie upon the ballast, depth of ballast and its bearing upon the subgrade, developed the track design shown in Fig. 1. The sizes on the drawing are for 60,000-pound axle loads. The principal sizes for 50,000-pound loads, using various weights of rail, are given in Table I.

Table I.

Rail	80 pounds	90 pounds	100 pounds	Rail with Sec. Mod. 20
Axle load	50,000	50,000	50,000	60,000
Size of ties	7″x 8″x 8½′	7″x 8″x 8½′	7″x 8″x 8½′	7″x 9″x 8½′
Spacing of ties	16½″	18″	20″	20″
No. of ties 33-foot rail	24	22	20	20
Depth of ballast	14″ stone	16″ stone	18″ stone	12″ stone 12″ gravel
Width of roadbed	21′	21′	22′	24′

From this table it is at once seen that the number of ties per 33-foot rail, as well as the depth of ballast, is much greater than that found in standard track to-day, and, since the figures in the table are the result of a careful consideration of the strength of the materials involved,

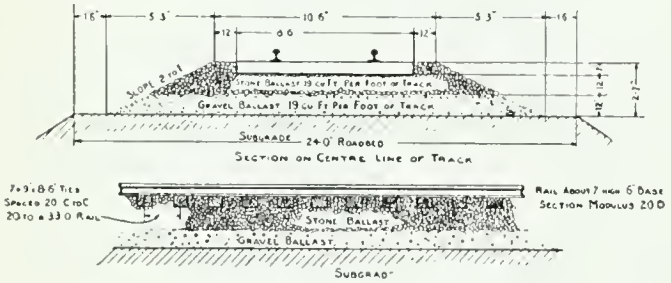

Fig. 1.—Track Superstructure for 60,000 lb. Axle Loads.

it is not surprising that the question of strengthening our present standard tracks is becoming such a live one, especially with our heavier trunk lines.

*Abstract from paper as presented to the Franklin Institute and published in the Journal of the Institute for August, 1913.

The depth of ballast, computed by Mr. Selby, was obtained from formulæ for the thickness of ballast necessary to produce equal distribution of axle loads on the surface of subgrade beneath the ballast, for which Mr. Thomas H. Johnson, consulting engineer of the Pennsylvania Lines West of Pittsburgh, was responsible. Mr. Johnson deduced these formulæ after studying a report, made by Railroad Director Schubert, of Berlin, in 1899, of observations extending over a period of over three years, on the action of ties actually in track. This report was translated and published by Mr. W. C. Cushing, chief engineer, maintenance-of-way, Pennsylvania Lines, and appeared in Bulletin No. 76 of the American Engineering and Maintenance-of-way Association, June, 1906.

In Mr. Johnson's formulæ the two following premises are made:—

1. "That the width of distribution of the load is equal, for stone ballast, to the width of the tie plus the depth of the ballast, and, for gravel ballast, to the width of the tie plus half the depth of the ballast."

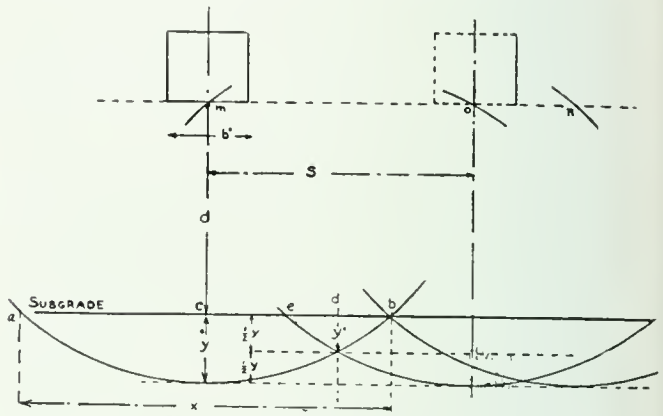

Fig. 2.—Width of Load Distribution Graphically Expressed.

From Fig. 2 this premise may algebraically be expressed thus:—

For gravel, $x = b' + \frac{1}{2} d'$.....(1)

For stone, $x = b' + d'$.....(2)

where x is the width of ballast pyramid carrying the load.

2. "That the intensities of pressure within that width are proportional to ordinates to an arc of a circle whose radius and chord are equal to the width of distribution of the load."

The deduction of the formulæ is as follows:—

If the circular arcs be considered as approximate parabolas, the intensities of pressure may be assumed to be proportional to the ordinates of the curves. The area of the parabolic segment = $\frac{2}{3}xy$, hence the mean ordinate = $\frac{2}{3}y$, or the mean pressure = $\frac{2}{3}$ the maximum.

The pressure at b is o, hence, to obtain an approximately uniform distribution of pressure over the surface of the subgrade, the tie-spacing S must be such that the curves overlap and have a common ordinate y′ equal to $\frac{1}{2}y$. This will obtain when db = $\frac{1}{4}$ cb; eb = $\frac{1}{4}$ ab or mo = $\frac{3}{4}$ mn.

Hence, the tie-spacing $S = \frac{3}{4}x$.

Therefore, from (1), for gravel, $S = \frac{3}{4}(b' + \frac{1}{2} d')$ and from (2), for stone $S = \frac{3}{4}(b' + d')$ from which the required ballast depths d′ are obtained by transposition:

For gravel, $d' = 8/3\ (S - \frac{3}{4} b')$

For stone, $d' = 4/3\ (S - \frac{3}{4} b')$

both of which give values of d′ much greater than exist in practice.

The question whether, in order to strengthen our tracks for the increased loads imposed, the number of ties or the depth of ballast, or both, should be increased, is one upon which opinions vary widely among those concerned. The following is here presented in this connection.

Fig. 3 shows a diagrammatic section of the ordinary standard main line track, in which 7-inch by 8-inch ties are spaced 22 inches apart, or 18 per 33-foot rail, and laid upon 6 inches of ballast. The slopes of the ballast pyramids, transmitting the load from bottom of tie to subgrade, are determined in accordance with Mr. Johnson's premises for the distribution of pressure at the bottom of stone ballast. It will be noted that the width of the base of the ballast pyramid under each tie is 14 inches and the width of the strip of subgrade unloaded and lying between adjacent ties is 8 inches. As shown by Director Schubert's experiments, and in line with the experience of all trackmen, the subgrade line, originally straight, will be disturbed, as AB in Fig. 4, the amount of disturbance being proportional to the weakness of the subgrade and to the ratio of the area of subgrade between the loaded ballast pyramids and that of subgrade beneath the ballast through which the load is transmitted.

By changing the tie-spacing to 20 inches, or 20 per 33-foot rail, as shown dotted in Fig. 3, the ratio of loaded to unloaded width of subgrade at the 6-inch depth of ballast becomes 14/6 instead of 14/8, an increase of 33⅓ per cent. The subgrade is more nearly confined, a condition which, of course, materially increases its carrying capacity. Maintaining the 22-inch tie-spacing and increasing the depth of ballast from 6 inches to 8 inches changes the ratio of loaded to unloaded width of subgrade from 14/8 to 16/6, an increase of approximately 52½ per cent.; while the combination of the decreased tie-spacing and increased ballast depth increases the original ratio from 14/8 to 16/4, or approximately 128.6 per cent.

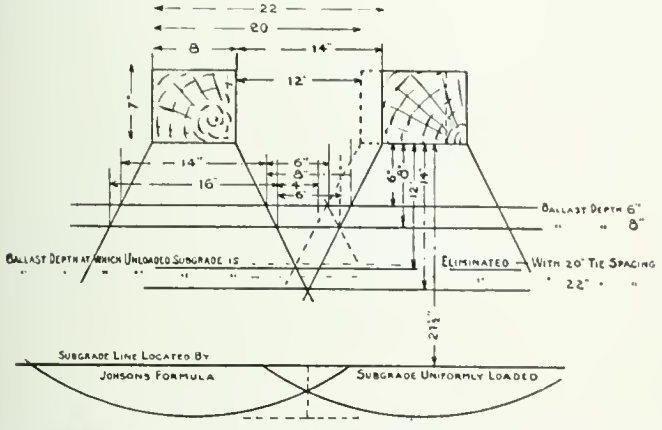

Fig. 3.—Section of Standard Main Line Track.

In the diagrammatic plan of track shown in Fig. 5 it is assumed that the rail load is spread by the tie 18 inches on each side of the rail centres, or, for an 8-inch tie, over an area of 36 times 8 = 288 square inches of the lower face of the tie under each rail, and over somewhat less than the 36 + 6 times 8 + 6, or 588 square inches of the subgrade. The corresponding area of unloaded subgrade is 42 times 8, or 336 square inches, and the ratio of loaded to unloaded subgrade areas is 588/336. Decreasing the tie-spacing to 20 inches will increase this ratio to 558/252, or 33⅓ per cent., while combining with this decrease, an increase of ballast depth of 2 inches, will increase the ratio to 588/168, or 100 per cent.

Fig. 5 also shows that with 18 ties per 33-foot rail the unloaded area of subgrade between adjacent ties becomes zero when the depth of ballast is increased from 6 inches to 14 inches, while with 20 ties per 33-foot rail it becomes zero with a ballast depth of 12 inches.

According to Johnson's formula for stone ballast, uniform distribution of subgrade loading will be obtained with 21⅓ inches of ballast for 18 ties per 33-foot rail and with 18⅔ inches of ballast for 20 ties per 33-foot rail.

Any consideration of the relief to be expected from decreasing the tie-spacing, increasing the depth of ballast or otherwise, should take into account the cost, and in this connection Table II. is presented.

From this table it is seen that a reduction of tie-spacing from 22 inches to 20 inches increases the ratio of width of loaded to unloaded subgrade by 33⅓ per cent. at a cost of $464, $928, and $1,856 per mile for single, double, and four-track lines respectively, while an increase of ballast depth of two inches (from 6 inches to 8 inches) increases this ratio by 52½ per cent. at the respective cost of $256.90, $507.23, and $1,006.51 per inch additional inches of additional ballast. Whether the first or the second or a combination of both is best is therefore somewhat of an open question.

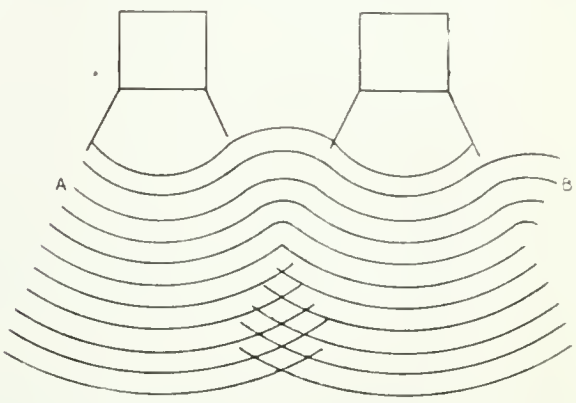

Fig. 4.—Lines of Distortion of Ballast Under Loaded Ties

Some individuals and committees have recently recommended a ballast depth greatly in excess of previously existing standards and still greater than the ballast depths actually obtaining even on our densely travelled lines, without qualification dependent upon either the subgrades or the characteristics of the imposed loads.

Table II.

Statement Showing Comparative Cost of Increasing Number of Ties per Rail Length (33 Feet) from 18 to 20 and Cost per Inch Depth of Putting Additional Ballast Under Standard Track of One of Our Larger Lines.

Ties per mile spaced	Single track.	Double track.	Four-track.
18 per rail length	2,880	5,760	11,520
20 per rail length	3,200	6,400	12,800
Additional ties	320	640	1,280

Cost per tie:

1 tie	$0.90	Volume of 1 tie, 3.3 cu. ft.
2 plates	.28	Cost of ballast, 75cts. per cu. yd.
8 spikes	.11	Cost of laying ballast, 40 cents per cubic yard.
	$1.29	Total cost of ballast in track, $1.15 per cubic yard.

Credit account ballast displaced	$0.14		
Net cost per tie	$1.15		
Labor placing tie in track	.30		
Cost per tie in track	$1.45		
Cost of additional ties in track.	$464*	$928*	$1,856*
Full width of ballast base.....	164½"	324½"	644½"
Cubic yards per square inch section per mile equals 1.35			
Cubic yards ballast required...	223.39	441.07	875.23
Cost of required ballast in track, at $1.15	$256.90	$507.23	$1,006.51

To the writer it appears that the design of railroad track must be approached in the same way as the design of any mechanical parts. As a foundation it should be treated like any other foundation, and a study of its requirements, purposes, construction, and maintenance should be made. It must be designed to carry loads of certain individual magnitude, density and speed, etc., and must do this upon subgrade of given conditions. With a sufficient amount of the right kind of data, it should be possible to combine the knowledge of the loads to be imposed with that of the subgrade conditions, and prescribe the most efficient and economical track construction, which, if it cannot be immediately provided, can be approached from year to year in connection with regular track maintenance work. Subgrade conditions vary materially within short distances, but with these conditions properly charted it should be a very easy matter, in bringing the condition of the track up to a desired standard, to concentrate effort upon those sections which are farthest from that standard and which will be located from tabulated or charted data or from the frequency of service failure.

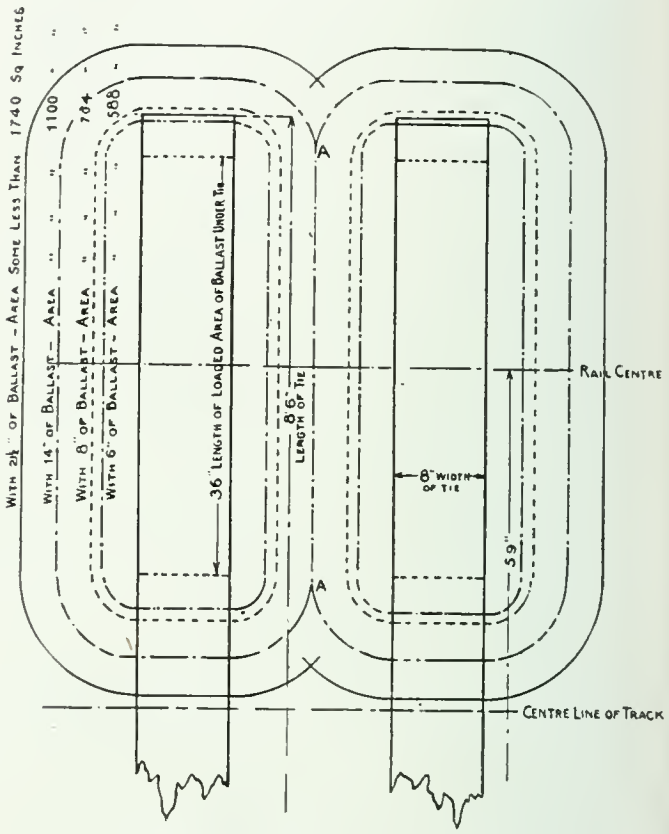
Opinions of maintenance men vary greatly upon a majority of questions relating to track and track superstructure design, and practically none of these opinions is supported by such conclusive test or experience as will make early agreement or reconciliation possible. In the maintenance-of-way department dependable data are not being collected as in the motive power department, in which department much money has been, and is continually being, profitably spent to settle questions pertaining to the design and operation of both locomotives and cars, many of which questions are of less importance than some of those relating to track construction.

The writers upon maintenance-of-way subjects will have served a useful purpose if they succeed in focusing attention upon the comparative deficiency of experimental work in this field, for as soon as this deficiency is realized then work will be inaugurated which will, in a few years, elevate the science of track construction to its proper level. The condition of our tracks is now lagging behind requirements, and we cannot consistently hope for a better state of affairs unless some move along scientific lines is soon inaugurated. In the meantime, locomotive and car designers must "mark time," so far as increased loads and speeds are concerned.

*Does not include labor cost of respacing present ties to make the insertion of additional ties possible, nor the cost of distributing the ties and ballast to point where placed in track.

While some investigations should necessarily be made under regular service, many can, nevertheless, be (and a few have been) carried out upon an experimental track of significant proportions. An experimental track was constructed a comparatively short time ago by the Prussian State Railroads at Oranienburg, Germany, and is being used to determine experimentally the best construction. Dr. H. K. Hatt, of Purdue University, who visited this installation a few years ago, reported:

"It consists of an oval track two miles in circumference over which runs a train consisting of electric locomotive and cars. At about every fifty feet two vertical rail ends were sunk in the ground on each side of the track and clips riveted onto them to serve as a reference



With 21½" of Ballast – Area Some Less Than 1740 Sq Inches
With 14" of Ballast – Area 1100 "
With 8" of Ballast – Area 704 "
With 6" of Ballast – Area 588 "
36" Length of Loaded Area of Ballast Under Tie

7" x 8" x 8' 6" ties spaced; 22" or 18" per 33' rail. Showing outlines and areas of loaded sections of subgrade with 6", 8", 14" and 21½" of ballast under the ties.

line, for measurement of track deformation. The service is considered as severe in one year as eight years on the main line. The cost of the roadbed and equipment is stated to have been $40,000.

"About a year before my visit the first track had become worn out and a new track consisting mainly of steel and beech ties had been set under service.

"Some of the elements which were being experimented with at Oranienburg may be listed as follows: Prussian standard steel ties with side ribs have been down one year in different forms of ballast. The evidences of derailment of cars were visible, but the steel ties were not sprung. The modern double steel tie was used at the joints. Various forms of anchorage of rails to ties were under experimentation. These anchors are found more necessary in steel ties than in the case of wood. The

various forms of anchors seemed all to be effective, although the track as a whole had not been down long enough to give final results.

"The scarf joint appeared to be unsuccessful, inasmuch as the inner edge of the scarf sheared off at the edge, due to the wave motion in the rail. The records of traffic passing over this experimental track show that in 369 working days the number of kilometre tons was about six million. In the months of January, February, March and April, in 1909, there were nearly seven million kilometre tons. The locomotive weighed 59½ tons and would pull a train of from 240 to 375 tons. The speed of the train was 60 kilometres per hour."

The loads imposed upon this experimental track are insignificant in comparison with those which, for the results obtained to be of service, would have to be placed upon such a track in this country.

The writer would suggest that an experimental track be designed and constructed in the form of a figure 8, so that one loop could be operated while the other was being prepared for test. On this track, properly enclosed by fencing, etc., a motor, hauling any desired combination of cars, loaded with any desired axle loads, could be controlled from the office of an engineer of maintenance-of-way tests located in the centre of either of the loops, and in this way any combination of rails, fastenings, ties, joints, ballast, frogs, switches, signals, and safety devices could be tested. The value of an ability, by this method, to rapidly test rails of different steels, under more scientific conditions, must be apparent when the amount of work done in settling rail questions during the last ten years is considered.

CANADIAN PETROLEUM.

The petroleum industry in Canada has been marked during the past four years by a rapidly decreasing output, the production in 1911 being only a little more than one-third that of 1907, according to statistics contained in the annual report on mineral production of Canada, by John McLeish, B.A. The total production of crude petroleum in 1911 was 291,092 barrels of 35 imperial gallons each, valued at $357,073 or an average of $1.22½ per barrel, as compared with a production of 315,895 barrels valued at $388,550, or an average of $1.23 per barrel in 1910, and 420,755 barrels valued at $559,604, or an average of $1.33 per barrel in 1909. With the exception of 86,139 gallon in 1911, 51,975 gallons in 1910, and 3,328 gallons in 1909, produced in New Brunswick, the output was entirely from the Ontario oil fields.

The above statistics of production are based on the claims made for the bounty paid by the Dominion Government, which was first provided for in 1904 by an Act passed by the Dominion Government authorizing the payment of a bounty of 1½ cents per gallon on crude petroleum produced from wells in Canada. The bounty was continued during 1910 under the "Petroleum Bounty Act, 1909," which provides for the payment of bounty on crude petroleum produced from oil-shales mined in Canada, as well as on oil from wells in Canada. Payments are made on claims submitted by the producers of crude oil to the Minister of Trade and Commerce. These claims have to be substantiated as to quantity by the certificate of the receiving stations, tanking companies refiners or other purchasers, as well as by the supervising officers of the Department of Trade and Commerce.

The bounty paid on the crude petroleum produced gives, therefore, as accurate a basis as is available for a reliable statement of the annual production.

A FEW COMPARATIVE COSTS IN ROAD AND PAVEMENT WORK.

By Fred. L. Macpherson, A. M. Inst. C.E.
Municipal Engineer, Burnaby, B.C.

ALTHOUGH the cost of roads and pavements naturally varies greatly in each city, or district, depending on local conditions, labor and materials, a comparison of the average prices obtaining in the vicinity of Burnaby, B.C., may be interesting.

Macadam Road.—Initial cost, 80 cents per sq. yd.; annual cost of oiling, .02 cent per sq. yd.; average annual cost of maintenance during the first three years of life, 11 cents per sq. yd.; cost applied over three years, $1.19 per sq. yd.; cost of scarifying and resurfacing usually necessary at the end of three years, 32 cents per sq. yd.

This means that in the fourth year of its existence an ordinary macadam road under average conditions has cost $1.50 per sq. yd., and even then it is far from being a permanent structure, being still susceptible to patching, scraping, oiling and resurfacing continually, thus increasing the cost of the road until, at the end of the fifth year or so, the macadam road has cost as much, if not more than, the initial cost of a bituminous pavement for which a usual five years' guarantee is given, and which is likely to last twice that time with comparatively little maintenance cost.

Further figures may be conclusive evidence of the extravagant construction of ordinary macadam roads. During the last three years there has been spent on our two principal highways, Douglas Road, 6¼ miles in length, $110,000, and Kingsway, 4¼ miles in length, $60,000. The latter is now being reconstructed at a total estimated cost of $400,000, for which the maintenance (except the cost of cleaning) of the actual pavement will cost the municipality practically nothing during the next ten years. Had this road not been paved, the repairing, resurfacing, oiling, etc., during that time would have cost $50,000—a very conservative estimate. Unless for purely residential streets, where it best fulfils its purpose, the ordinary macadam road should be a thing of the past. The present policy of borrowing money for 40 years for building roads with an average life of three years, and maintaining such roads out of revenue expenditure, seems to be radically wrong. An ordinary macadam road, far from being an asset, is nothing short of a burden, under such conditions.

The average cost of other pavements dealt with are:

Concrete pavements	$2.00 per sq. yd.
Hassam pavements, thickness, 6 ins.	2.25 per sq. yd.
Granitoid pavements, thickness, 7 ins.	2.65 per sq. yd.
Brick on city streets on 6-in. concrete	3.75 per sq. yd.
Brick on rural roads on 4-in. concrete	2.75 per sq. yd.
Dolarway pavement	2.20 per sq. yd.
Bituminous pavements—	
On concrete base	2.60 per sq. yd.
On old macadam base	1.25 per sq. yd.
On new macadam base	1.80 per sq. yd.

Based on an average cost of $25,000 per mile, 100 miles of bituminous pavements built on existing macadam or gravel roads in Burnaby would cost $2,500,000. While the initial cost of such work seems alarming, the investment should be a sound one if spread over a period of about five years, inasmuch as the work would be per-

manent, the average annual cost of maintenance, say, $50,000, at the end of that period would be practically eliminated and the needs of every district amply served.

Although on first consideration such an undertaking would appear to be stupendous and financially impossible for any ordinary municipality, the issues at stake are so serious, and the necessities so imperative as not only to deserve mature consideration but also to demand prompt action. Permanent initial construction is the proper policy for any municipal or government authorities to adopt. Municipal bodies are active in the permanent road policy, but unfortunately the action is not concerted enough and the results are therefore disappointing and ineffective.

The proper administration of highways is a prominent feature of road economics which has not had the earnest consideration locally which its great importance deserves. In view of the increasingly urgent demands for the opening up of new roads for settlers, and the improvement of existing residential roads, a municipality should not altogether be saddled with either the construction or the maintenance of through highways. Such roads and the roads to which they link up should be under a highway commission, composed of engineers and representatives of some more permanent public bodies, such as is in vogue in England and in portions of Eastern Canada and United States. The adoption of such an administration would assuredly make for uniformity and continuity of construction, and result in a more even and equitable assessment of expenditures involved.

The provincial governments appear to be alive to the situation and have adopted progressive permanent measures in their road construction policy. Financial assistance is now given chiefly for permanent work, and, locally, Burnaby and South Vancouver have reason to be greatful for the material assistance received in the permanent paving of Kingsway.

There are many other interesting and important features associated with the question of semi-permanent and permanent roads and pavements, but the above remarks may serve to prove that progress towards the better highway and the better street, in which we are all so intimately interested, must be along lines that are utilatarian, logical and aesthetic, and further, that the wish for a more permanent highway will be visionary until the need for it is created and its claims urged upon the powers that be.

The total value of the sales of sewer pipe in 1911 statistics as contained in the annual report on Mineral Production of Canada by John McLeish, B.A., was $812,716, as compared with a value of $774,110 in 1910, and a value of $645,722 in 1909. Nearly 50 per cent. of the production in 1911 was made in Ontario. Following is a list of firms that reported production of sewer pipe in 1911: Standard Drain Pipe Company, St. Johns, Que., and New Glasgow, N.S.; Ontario Sewer Pipe Company, Toronto, Ont.; Dominion Sewer Pipe Company, Toronto, Ont.; Hamilton and Toronto Sewer Pipe Company, Limited, Hamilton, Ont.; Clayburn Company, Limited, B.C.; British Columbia Pottery Company, Victoria, B.C. The imports of drain pipe and sewer pipe during the calendar year 1911 were valued at $382,029, of which $338,644 worth was imported from the United States, $44,278 from Great Britain, and $7 from other countries. The production of drain tile as reported was not as large in 1911 as in 1910 or 1909. The total sales in 1911 were valued at $339,812, as against $370,008 in 1910, and $408,440 in 1909.

FOREST DEVELOPMENT AND PRESERVATION.*

By R. H. Campbell, Esq., Director of Forestry, Ottawa.

IN considering the forest and its development, it is necessary to have clearly fixed in our minds the fact that the forest is a living thing, and that it grows and develops according to natural laws. In order to understand the forest, therefore, it is necessary to study the habits of life of the tree. The four great requirements for tree life are water, light, air and soil. The tree carries on its functions of life and growth very much in the same way as animals do. One of the great differences, however, is that the tree is in a fixed position and therefore cannot go to find its food or requirements where they may be. It is therefore necessary for it to adapt itself to the conditions as they exist where it is located. We will look at the materials which the tree requires for its growth, and then consider some of the adaptations that are necessary so that the tree may make use of them.

Water is the most important constituent for the use of the tree. The tree is continually drawing up from the earth through its roots, large quantities of water which pass up from the trunk and are exhaled from its leaves. In order to keep the tree in a healthy condition this flow of water must be kept constant, and the more freely the water passes through the tree the more vigorous will be its growth. We see this very clearly by following different characteristics of the tree growth in different portions of the Dominion. On the coast of British Columbia, in a moist climate, the growth of the tree is very vigorous and we have the immense Douglas firs and cedars that form one of the most magnificent forests in Canada. In the forests of the Selkirk Mountains in the central part of British Columbia where the rainfall is still heavy, there is a vigorous growth of white pine, cedar and fir. In the dry belt in the province of British Columbia, the mountains which receive the most of the precipitation are covered with a dense forest of lodgepole pine and fir, but in the lower portion of the dry district, where the rainfall is scanty, the forest thins out and there is a scattered growth of yellow pine. In the prairie country the Rocky Mountains carry a stand of lodgepole pine, Englemann's spruce and fir, which is more or less of a mountainous character, and therefore not so large in size as the forests of the Selkirk Mountains or the coast of British Columbia. The reason for this is that ascending the mountains or going northward in latitude the soil is cold for a longer period during the year, and this has a considerable effect on the rate of growth of the trees.

The trees are not directly affected by the lowness of the temperature, as some specimens of trees are found growing in the barren lands to the north, away beyond the general line of tree growth. The effect of the cold is, however, to keep the ground frozen for a great portion of the year, and therefore to prevent the tree from obtaining a supply of water with the result that is cannot continue its functions. In the muskegs of the north country the trees are very slow in growth and stunted. This is partly the result of the fact that the ground is kept very cold by the covering of moss, and therefore the growth is slow, but it is also partly due to the fact that there is considerable acid in the water of the muskegs and consequently

*Read at the Seventh Annual Meeting of the Association of Dominion Land Surveyors, Ottawa, March 5th, 1913.

the tree cannot make use of the water as it could if it were pure. The method by which the water passes from the outside of the rootlets to the inside is a physical one dependent on chemical composition. If the water outside is a stronger solution than that inside the root, the water will not pass in and consequently the tree cannot get the use of it.

As you reach the northern latitudes or the alpine elevations of the mountains, the tree growth becomes more stunted until finally it lies almost like a mat on the surface of the earth, as illustrated by the view of the white barked pine at an altitude of 6,000 feet on the Porcupine Hills in Alberta. This flattening out of the growth is partly due to the fact that the water supply is not sufficient, and that it is difficult to get the water pumped up if the tree grows to a greater height than the ordinary level, and partly to the fact that the drying wind increases so largely the transpiration that the supply of water cannot be obtained quickly enough in a soil which is so cold for such a great part of the year.

To counterbalance the great extent of the tree above ground, it is necessary also that the root should extend deep and wide in the earth in order that the tree may not be overthrown by the wind. The growth of the tree in this manner is not, however, the most satisfactory for producing lumber, as the lumber produced will be knotty and will have a very small proportion of clear stuff. In order to produce the best quality of lumber the tree should be grown in a close stand. Where the trees have been sown close together and are reaching upward toward the light, each one tries to get its crown where it can get the most light. As a result the trees grow rapidly upward and the inside branches dry off and gradually drop from the tree, leaving a long, clear trunk. Many of the trees in such a stand will finally become suppressed by the more vigorous ones and will gradually die out completely. In the forests of Europe such trees would be taken out by a thinning process, but in this country the market conditions do not make such thinnings possible, although in a district like the Cypress Hills, of Alberta, where there is no other timber within one hundred miles, there seems to be reason why thinning might be done profitably.

The soil has considerable influence on the growth of trees. We find that on the light, sandy soils the pine will grow readily, particularly the red pine and the jack pine. As a rule, however, trees will grow best in a fairly good soil, and the forest floor covered by leaves and debris from the trees finally forms a bed of humus which provides excellent nourishment for tree growth. The province of Ontario is now taking active steps to replant pine on some of the sandy areas in the western part of the province, which have been entirely denuded and left bare of trees or any other useful growth.

In order to meet the different conditions as explained above, the tree has to arrange various adaptations. Sometimes the tree is in a location where water can be obtained plentifully, and in such case it is arranged that water will pass through the tree rapidly and escape. Such trees usually have broad leaves with thin coverings and numerous openings called stomata from which the moisture may escape. Trees or plants growing in dry situations, on the other hand, have devices for retaining the water as long as possible. One of the clearest examples of this, is the cactus growing in the deserts of the western United States, and even in the dry districts in the southern part of the prairies. The cactus has thick leaves containing a great many water vessels, and these leaves are covered with a close covering through which water cannot pass very easily. As a consequence all the water which the plant draws up from the earth is retained in the plant with almost no loss.

While the tree draws up water from the earth, bearing a few mineral salts, its chief sustenance is the carbon drawn from the air through the leaves. The fact that the tree is largely composed of carbon can be seen in any burnt district. The carbon is supplied largely from carbon dioxide in the air. In order to carry on its process of obtaining the carbon from the air, which process is carried on by assimilation in the leaves, it is necessary that light should play upon the leaves as fully as possible. Consequently the leaves are spread out so as to catch as much light as they possibly can. This is illustrated by the broad, flat leaf of the maple, arranged upon the stem so that the broad, upper portion of the leaf should always be exposed as much as possible to the sun. In the case of the coniferous trees the leaves are small, but this deficiency is made up by their leaves being very numerous.

The stem is so arranged as to provide for the water supply from the root passing up readily, and it is a very interesting process to investigate. It is not yet clearly understood how the force is supplied which will drive up the water required for one of the giant trees on the Pacific Coast two or three hundred feet through vessels of microscopic size. Various theories in regard to the matter have been put forward, and it was thought at one time that the matter was settled by an explanation that the pulsations of the living cells of the trees resulted in a pumping process which gradually forced the water upward. This theory is not, however, accepted as final at the present time.

Each year of growth adds a distinct ring to the woody tissue of the tree. In the spring the cells of wood are large with thin walls, and late in the summer are small with thick walls, and this makes the distinction between the growths of different years. The growth of a year may be larger or smaller according to the season. The favorable season will make the ring of growth larger, and a dry season will make it considerably narrower. Trees which are suppressed will also make slower growth than those which are open to light and air.

The bark gives protection to the growing parts of the trees, and as the tree increases in size the outer bark dies and is split open by the pressure from the inside, resulting in the corrugated bark which is so characteristic of many trees. The rough bark is characteristic of the white pine, elm and many other species. The bark in other cases, like the spruce, strips off in flakes, and that of the white birch exfoliates in thin sheets.

There is added to the natural conditions which have to be considered in the growth of the trees, an artificial condition caused by fire. Fires have occurred in all our wooded districts, and the evidence of their destructive power is clear to any person who has travelled through the timbered districts. Fires make the condition more difficult inasmuch as they make it harder to carry out the protection of a forest, and that they have made the conditions for reproducing the forest more difficult than they would be naturally. Where a tract is well covered with forest trees the cutting can be done so as to favor natural production, but where a forest fire sweeps through, the conditions are changed without regard to what is to follow, and we have to try afterwards to bring about the conditions that would have been considered and provided

for if the removal of the forest had been done in a regular way. The vast stretches of forest that have been destroyed by fire mean a great loss to the capital and industry of the country, and means for combatting them are of prime importance.

The methods taken for handling the forest on better principles are:—

1. The provision of a fire patrol. We have a large number of fire rangers patrolling the forests by foot, by horse, by canoe or boat, during the dangerous season in the summer. These men put up notices warning people of the danger of fire, and instruct every person that they meet as to the necessity of taking care in the use of fire. On the Saskatchewan River, and one or two other places, we have put on a patrol boat. In such cases there are large stretches of water from which the forest can be reached and in this way a very much larger area can be patrolled than can be done in any other way. The work of the fire patrol may be illustrated by the work that is done in the portion of Manitoba north of Lake Winnipeg. This district is in charge of Mr. Jas. T. Blackford, with headquarters at Norway House. The canoe routes for the country to the north and down towards Hudson Bay all start from Norway House, and here he has an opportunity of meeting the parties that are travelling and warning them in regard to the danger of fire when they are starting out. Fire notices are posted at all the portages along the canoe routes, so that the matter is brought immediately to the attention of any parties when they go into camp. Mr. Blackford has also been successful in interesting the Indians in the matter of fire protection. He has talked to them about the matter when they are gathered for treaty payment and has induced them to promise to put out their own fires and have others do the same. Every one of the Indians who promises to do this receives a small fire ranger's badge in the shape of a maple leaf, and they are very proud of these badges and wear them all the time.

On the forest reserves where matters are more fully under control, and the line between agricultural and forest lands is permanently settled, we take further steps for fire fighting by making permanent improvements of various kinds. In a tract like the Cypress Hills, where the prairie comes immediately in contact with the forest, plowed fire guards are made so as to prevent prairie fires sweeping into the timber. Such fire guards have been found of great advantage in holding back fires. Telephone lines have been erected in order to have communication through the forest with the object of getting word about the fires out quickly and getting help in to fight them. In the forests of Europe the telephone is being largely used, and it is also being used very considerably on the forest reserves of the United States. It is one of the most useful adjuncts to the fire preventive work that can be had. The work of fire prevention in the forests is on the same principle as the work of fire prevention in the city; that is, the fire must be located quickly; notice of it must be given without delay; and help must be got to it speedily. This means the opening up of communication of all kinds—trails, roads, telephone lines, etc.

Another matter that has to be dealt with in order to meet the fire difficulty is the disposal of slash resulting from lumber operations. The condition of the forest after lumbering operations is such that the ground is covered with the debris of tops and branches forming fuel for a fierce fire and one which it is almost impossible to fight. The methods proposed for disposing of this debris is to have it piled and have it burned at a season when there is no danger of its spreading. Another method is to have the lower and upper branches of the top lopped so that the top will fall flat on the ground and rot away more quickly. This reduces the time of the danger by a few years, but until the tops rot it leaves a dangerous situation. On the whole the best method will be to pile the tops and burn them, and in Minnesota it has been found that this work can be done for 25 cents per thousand feet board measure. In Europe, all material produced by the forest is of value so that the question of the disposal of slash is not a difficult one there. It will be many years before that condition is reached in Canada.

In order to provide for replacing cut over forest by a new growth there are two main methods; one is to do the cutting so as to leave seed trees or groups of seed trees so that a supply of seed may be furnished for the reproduction of the trees. In Canada the natural reproduction is good, as a rule, and as the method of artificial reproduction is somewhat costly, the former method will be followed generally. However, in some cases the forest has been so depleted on lands that are non-agricultural that it is necessary to make arrangements for reforestation. Such a tract is that in the Spruce Woods Forest Reserve in Manitoba, and we have started a nursery there with the object of growing young trees and replanting the denuded areas from the nursery. The method used is that of establishing seed beds in the nurseries and transplanting the trees into the larger beds before they are finally ready to plant out in the forest at the age of about three years. When the trees have reached that age they are planted out in the place where they are to grow finally. In the western prairie district the trees are usually planted about four feet apart in order to give them as much protection as possible. Planting at this distance will mean that considerable thinning should be done at a later stage, and possibly by the time the trees have reached that stage thinning will be a commercial possibility. In many cases, however, the trees are planted as much as eight feet apart.

The whole object of the work that is being undertaken is to finally produce forests where there is a regular stand of clear timber producing a large quantity of wood regularly every year. The danger of not looking after the tree growth is in evidence on the bare and denuded mountain sides of many places in China where forests once flourished; on the bare, rocky hillsides in the Holy Land where a few small shrubs and grasses are gathered for fuel; and on the bare mountain sides of several districts in France where millions of dollars had to be spent for works to control the flow of torrential mountain streams and to replace the forests which have been destroyed by fire and close grazing.

The American Bar Association and the American Bankers' Association have each authorized special committees to co-operate with the management of the American Road Congress in the holding of sessions at Detroit to deal respectively with road legislation and the financing of road improvement. An effort will be made at the legislative session to bring about the formation through official channels of a national committee to codify State road laws and recommend simple and uniform legislation for each State and the elimination of the great accumulation of conflicting and confusing road laws. The finance section will endeavor to have adopted in all parts of the country simple and effective methods of road accounting and a record of such cost data as may be essential to the proper conduct of road work, and will also deal with the important subject of bond issues.

PREVENTION OF WASTE OF FLOWING OIL AND GAS.

METHODS for the prevention of the tremendous waste that usually accompanies the "coming in" of wells producing large quantities of oil or gas by natural flow fall naturally into two classes, preventive and remedial. The first have to do with keeping under control whatever gas or oil may be encountered in the process of drilling; the second relate to the capping or subduing of wells that have "gone wild." Both are dealt with fully in a bulletin prepared by R. Arnold and V. R. Garfias, and recently issued by the U.S. Bureau of Mines. Of these the preventive methods are likely to be of interest in the Canadian field, and are outlined here with that in view.

A few general conditions affecting flowing gas and oil wells are as follows:—

1. The gas from gas wells and the gas that generally accompanies the oil is not injurious to health, hence workmen may labor near the well without being harmed.

2. Owing to the usual tremendous velocity of the stream of gas, the part immediately over the casing head is like a smooth column, and may be approached with safety.

3. The sand usually expelled under tremendous force with the oil or gas often wears out the casings, but this wearing action generally takes place only throughout the uppermost 30 or 40 feet and opposite or near the place where the gas enters the well, thus leaving the main part of the entire length of the strings practically sound.

4. The great volume and tremendous pressure of the gas and oil make the use of the best fittings a necessity. Some of these, being of special sizes, are made to order.

For convenience, and in accordance with common usage, the flowing oil wells and the gas wells discussed herein are designated respectively as "gushers" and "gassers."

With the present state of our knowledge regarding the situation of the "gusher" and "gasses" strata in the developed fields, there is no excuse for the general lack of precautions taken before the depth is reached at which the flow is expected. Furthermore, if the well is being drilled in a new or prospective field, adequate precautions should be taken so as not to jeopardize in advance the possible profits of such an uncertain and expensive undertaking. The additional cost of the safety devices is insignificant in comparison with the total cost of drilling such wells and with the amount that can usually be saved if their rate of production is regulated. It may be safely stated that practically all of the great waste resulting from the unrestricted flow of gassers and gushers can be prevented easily by known means which generally are within reach.

Controlling the rate of production of the well has a direct bearing on the returns to be derived from the product. There are times when, owing to the market conditions and the transportation and storage facilities, the "bringing in" of the well might be an unwelcome event, as was strikingly shown in the case of the Lake View gusher. Experience also shows that a gasser or gusher will yield a greater total production if allowed to flow only a fraction of its capacity, the famous Huasteca No. 7 well in the Mexican oil fields affording a most remarkable example. This gusher has been flowing under perfect control for about 2½ years, yielding about 23,000 barrels per day under a pressure of about 285 pounds.

One of the most successful apparatus devised with a view to controlling whatever flow of oil or gas is encountered is the blow-out preventer, which has given general satisfaction, particularly in drilling by the rotary method.

Description of Apparatus.—The blow-out preventer is a modified type of a stuffing-box casing head, which in turn is an addition to the four-way **T**. The immediate object of the preventer is to control the flow of oil or gas between two strings of casing, and naturally its use is better adapted to drilling by the rotary method in which the circulating water keeps an open space between the inner casing and the wall of the hole. An idea of its operation may be gained by imagining a four-way **T** attached to the top of the last casing set or landed and the inner casing passing through the **T**, the flow of oil or gas between the casings being deflected to the lateral openings of the **T** by closing the annular space between the inner casing and the upper part of the **T** by means of a stuffing box. In the preventer the stuffing box can be removed or put in place by turning adjuster screws which operate slips provided with hydraulic packing that fit around the inner casing as an adaptable split valve. To the lower opening are bolted interchangeable screw flanges to fit standard casings from 6 to 12½ inches in diameter, and to the opposite opening are attached suitable guide plates to prevent the wearing of the inner parts of the apparatus by the revolving inner casing. These guide plates are made to fit casings from 8 to 2¼ inches in diameter. The lateral openings are threaded to fit pipe 6 inches in diameter. The apparatus is manufactured of cast steel and lined with babbitt metal, being tested to stand a pressure of about 2,000 pounds per square inch.

Mode of Operation.—To insure the successful operation of the preventer, careful attention must be given to all the details, such as welding the bars, fitting the small pins that secure the wrench to the screws, and providing a suitable place outside the derrick for the man who is to operate the wrenches, etc., as soon as the apparatus is put in place.

The preventer, when used, is always placed on the last string of casing set or landed, thus controlling the flow between that string and the drill pipe or casing that is being lowered. The slips should be in a position to be clamped around the drill pipe, but should not be kept too near it, in order to avoid possible damage to the hydraulic packing. If the well is being drilled with a rotary rig, the back-pressure valve inside the drill pipe will effectively prevent any flow upward through this casing, and if the standard rig is used, a heavy gate valve, which can be closed after removing the drilling tools, is placed on top of the inner casing. The only outlet left is the space between the casings, and the flow through this opening can generally be controlled by clamping the split valve of the preventer around the drill pipe and closing the gate valves on the pipes connected to the two lateral openings.

It sometimes becomes necessary to exclude from the drill hole water or gas found in an overlying sand in order to control the well or to recover or test the oil below. This end can be easily accomplished in drilling with a rotary rig by forcing muddy water to the bottom of the well through one of the lateral openings of the preventer, the pressure being regulated by closing the valve connected to the other opening. A back-pressure valve in the drill pipe will prevent the flow of the mixture through this casing. By drilling a short distance and forcing as much mud as possible into the porous sands penetrated, a

plastered wall of clay is built throughout the gas-bearing or water-bearing strata. After the entire thickness has been penetrated and the casing landed in an impervious bed, another string may be used to tap the oil sands below. The gas thus excluded can be recovered afterwards by drilling shallower wells to the upper sands.

This method can also be employed in drilling the entire thickness of a gas or oil sand under tremendous pressures, an operation that might otherwise prove troublesome. The mud can easily be removed by releasing the pressure or bailing down the water in the hole, a strainer or perforated casing being placed in the sand to prevent the wall of the well from caving when the pressure is released.

Testing of Supposed Oil or Gas Sands.—It is often advisable before drilling is continued to ascertain whether certain beds carry oil. The work involved is often accompanied by accidents and loss of time, as the material may collapse and pack around the casing, thus preventing its removal or further lowering. Many such accidents can be avoided and the required tests made by using a preventer or a stuffing-box casing head in the following manner.

After the preventer has been attached to the last casing set, a special shoe about 8 feet long is attached to the bottom of the inner casing, and this is lowered to the bottom of the hole and driven down into the formation, making a water-tight joint. The split valve of the preventer is then closed. A pump is connected to one of the lateral outlets, the valve on the other being kept closed to control the pressure in the well. Muddy water is then pumped in, and the pressure between the casings is increased in order that the formation will not cave in and "freeze" the inner casing. While the pressure is maintained the column of fluid in the inner casing is bailed out. This fluid being a representative sample of that which came from the formations passed through should show the presence of oil if any has been encountered. Great care should be exercised in bailing, as the casing may happen to be in such condition that it will not withstand the outside water pressure.

Precautions Against Fires.—Perhaps the greatest individual losses in connection with flowing oil and gas wells have been caused by conflagrations which in most instances could have been avoided by proper precautions. In such conflagrations the gas, owing to its lower flash point, is generally set on fire before the oil. Ignition may be caused by fires under boilers or in forges, by unprotected lamps, burning matches, or spontaneous combustion at the bearings of the calf wheel, bull wheel, headache post, or band wheel in the engine house. It is also claimed that the friction of pebbles striking each other or rubbing against the casing as they are expelled with great force with the gas or oil may cause sparks that will set on fire the more inflammable hydrocarbons. In certain oil fields fires caused by lightning are comparatively numerous.

The prevention of these fires depends on the proper control of the flow of gas and oil, the ventilation of the space immediately above and near the well so that no gas will accumulate, and the keeping of boiler fires, forges, lamps, burning matches, poorly insulated electric wires, etc., at such a distance or in such a position as to eliminate danger.

The most effective means employed for subduing gas or oil fires has been the use of steam discharged in great quantities and under high pressure against the lowest part of the flame. Well cappers have also been used successfully. Nature at times comes to the rescue by temporarily stopping the flow when the well "sands up." On the other hand, the flow may render human ingenuity powerless by destroying the casing and forming a veritable oil volcano, as was the case in Mexico with the famous Dos Bocas well.

UNITED STATES CEMENT PRODUCTION, 1912.

The United States Geological Survey will shortly issue a bulletin, "The Mineral Resources for 1912," which will contain the following data concerning the quantities and values of cement produced in that country during the past three years:—

Class.	1910. Quantity (barrels).	1910. Value.	1911. Quantity (barrels).	1911. Value.	1912. Quantity (barrels).	1912. Value.
Portland	76,549,951	$68,205,800	78,528,637	$66,248,817	82,438,096	$67,016,928
Natural	1,139,239	483,006	926,091	378,533	a 821,231	367,222
Puzzolan	95,951	63,286	93,230	77,786	a 91,864	77,363
Total	77,785,141	$68,752,092	79,547,958	$66,705,136	83,351,191	$67,461,513

a Shipments.

Prices.—According to reports made to the Geological Survey by the manufacturers, the average price by districts of Portland cement per barrel in 1912 in bulk at the mills ranged between 67.4 cents in the Lehigh district and $1.358 on the Pacific coast, as compared with 71.5 cents and $1.406 for the same districts in 1911. The average price for the whole country was 81.3 cents in 1912, as compared with 84.4 cents in 1911, a decrease of 3.1 cents a barrel. The average price in 1912 reached the same level as in 1909, and is the lowest point recorded for Portland cement. The lowest average price reported to the Survey was 62 cents a barrel, received at several plants in Pennsylvania, and much cement was sold as low as 65 cents, not only in the east, but in the middle west. The highest figure reported was $1.65 a barrel, reported by a California plant.

A subject which will be taken up at the contractors' session of the Road Congress, at Detroit, which should prove of special interest to road contractors is the "Protection and Upkeep of Road Equipment." An immense amount of money is lost through failure to protect and properly maintain costly road machinery and equipment. Another subject which will be presented by a trained specialist is the "Organization and Arrangement of Working Forces." It is quite a problem to place the road hands of a big force so as to avoid waste of time and money, and this subject should bring out much useful discussion. A special committee of three of the most prominent engineers and contractors identified with contract work, of which Mr. J. R. Wemlinger, secretary American Society of Engineering Contractors, is chairman, will have charge of the programme of the contractors' session.

FOUNDATION WORK ON C.P.R. BRIDGE AT MUD LAKE, ONTARIO.

THE Canadian Pacific Railway Company's low-grade freight line, now building between Toronto and Perth, Ont., crosses Mud Lake some 150 miles north-west of Toronto, and foundations for a single-track bridge at this place are now nearing completion. The bridge, when constructed, will have a length between the parapet walls of the abutments of 953 ft. 7½ ins., and an extreme height above rock foundations of 105 ft. Fig. 1 is a general diagrammatic sketch showing design. It will be supported upon four piers, two sets of pedestals of four each, for column support, and two abutments. The bridge site is some six miles from the railway station. This signifies that the entire plant as well as supplies has had to be transported over land by wagon over hilly country, and since the main plant, aside from such auxiliary plants as are ordinarily used on such work,

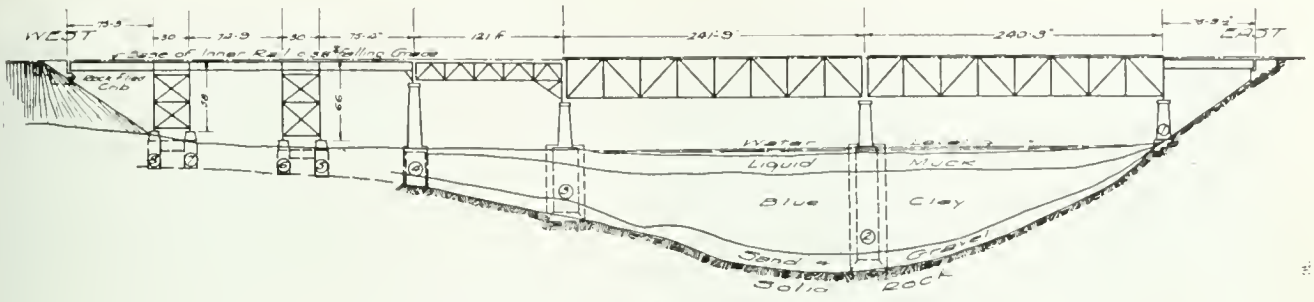

Fig. 1.—New Canadian Pacific Railway Bridge Over Mud Lake, Ont.

Fig. 2.—General View, Showing Piers No. 1, No. 3 and No. 4 Completed.

consisted of three 90-h.p. Loco boilers weighing some 20 tons each, and two air compressors of practically the same weight, the difficulty attending the installation of plant may be understood.

Geological Condition of Site.—Mud Lake lies in a pocket surrounded on three sides by high hills. It derives its name from semi-liquid ooze lying in a mass almost from the surface of the water to the hard-pan some 86 feet below it at the lowest point, which is where Pier No. 2 is located, presenting a formidable opposition to the sinking of caissons under air on account of its low bearing value both in friction and in compression, while in density it could well be classified as soft, blue clay. Despite all its depth of mud to be contended with, the route across Mud Lake chosen by the railway engineers presented to them fewer difficulties than an alternative location among the granite hills surrounding it; and besides, it enabled them to maintain that distinctive feature of the new route, i.e., its low-grade line.

Active work was begun late in March of this year and was continued night and day since then until the beginning of August.

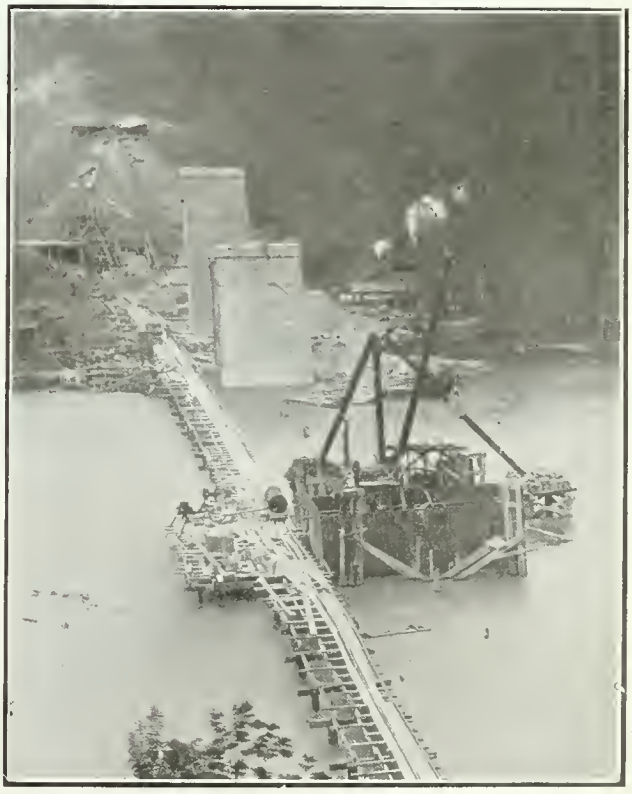

Fig. 3.—Caisson for Pier No. 2 Being Sunk.

Of the four piers, Nos. 2, 3 and 4 were sunk under air pressure; No. 2 to a depth of 103 feet 4 inches, No. 3 to a depth of 59 feet, and No. 4, 40 feet. Except for the last thirteen feet, which consisted of quicksand and

boulders running into hardpan, the materials which these piers replaced were liquid muck and solf, blue clay. The foundations for Pier No. 1 and pedestals Nos. 5, 6, 7 and 8 were sunk in open sheet-piling cofferdams.

All foundations and piers are being constructed on concrete in proportions of 1:2:4 and 1:3:5 and rest upon solid rock. Sand for the concrete is procured from a pit some two miles from the bridge site and is delivered by wagon. Stone is quarried and crushed at the bridge site.

The mixing plant consists of a one-yard steam mixer located near the west end of the bridge. The concrete is transported in dump buckets on cars over a track supported by a pile trestle reaching across the lake, and is handled into the work by means of stiff-leg derricks.

Figs. 2, 3 and 4 show general arrangement of plant, shore conditions, and progress of the work up to about three weeks ago. The massiveness of the concrete piers is well indicated.

The deepest of the two caissons sunk by pneumatic method, viz., Caisson No. 2 was 34 x 20 feet outside dimensions, provided with two dredging wells 8 ft. 8 in. by 9 ft. inside dimensions. Owing to the soft nature of the material and the despatch with which it was necessary to sink these caissons, they were sheeted and braced like an ordinary wood caisson with steel cutting edge, the walls of the working chambers being reinforced with rods. The elimination of forms thus enabled the sinking to be carried on continuously night and day.

After the caisson was dredged to a depth of 40 feet, it was deemed advisable to place the reinforced concrete deck, which was accomplished under water, being by no means an easy task, the remaining 63 feet being sunk under air. In this deck the shafting was embedded and carried to the surface above water level, on the top of which the air lock was placed.

Caisson No. 3 was the same size, only the depth being so much less makes description of its progress unnecessary.

Sinking a caisson to a depth of 103 feet 4 inches, as in the case of Pier No. 2, requiring a maximum air pressure of 47 lbs. to the square inch, is an undertaking that does not permit of methods other than those well tried and proven. Particular care was exercised for the safety of labor employed on the work. Only men with previous experience on caisson work were engaged. The time interval to which they were subjected to this excessive air pressure was forty-five minutes, and in spite of all precaution, careful attention and surgical aid, the "sand hogs" were not all the time immune from the "bends" and paralysis. A hospital lock was in commission at Mud Lake, and those afflicted during the sinking of the caissons were speedily treated by the usual air method.

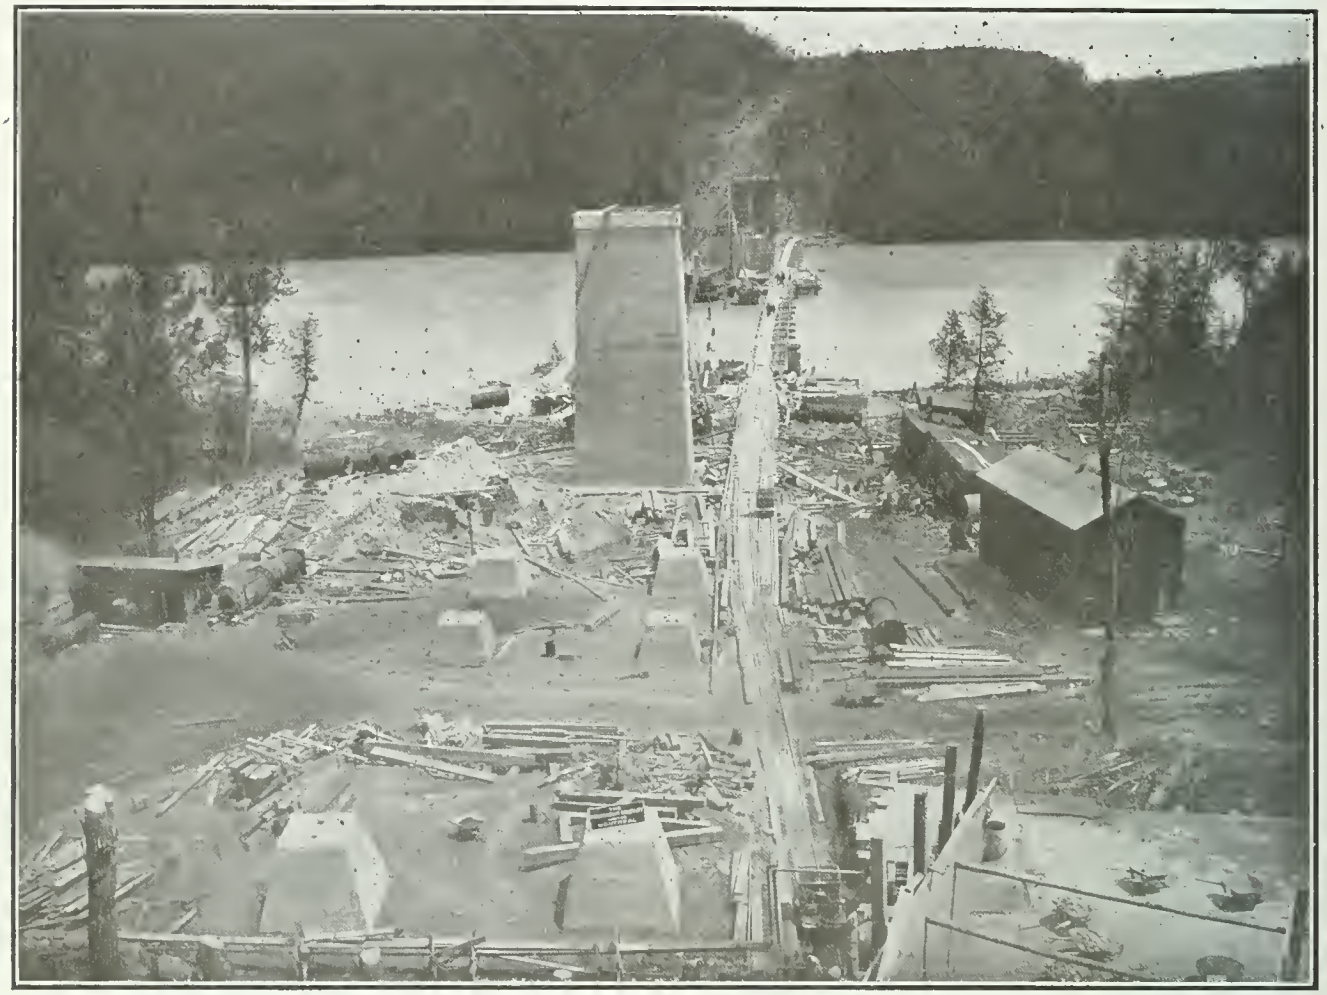

Fig. 4.—Bird's Eye View Looking East, Showing Pedestals for Steel Work, and Pier No. 4 in the Foreground.

The work at Mud Lake was carried out under the direction of C. W. P. Ramsay, Esq., engineer of construction, from design of P. B. Motley, Esq., engineer of bridges, for the Canadian Pacific Railway. The foundations for Mud Lake bridge were built by The Foundation Company, Limited, of Montreal and Vancouver, Mr. A. I. Campbell, superintendent.

MUNICIPAL ENGINEER AND EMPLOYER.

The uncalled-for subordination which some members of civic boards would like to see their engineers exhibit, is, to the unprejudiced and fair-minded observer, an apt illustration of the fact that engineering and its problems are but minor details, in comparison with other difficulties with which the municipal engineer is confronted. A case was recently cited in the Western press. It relates to the indignant tone of a committee meeting at which the engineer's report upon a certain phase of construction work was being read. A point, with which the engineer had apparently taken for granted that every member of the board was familiar, required further elucidation. The engineer being absent and efforts to locate him failing, an alderman abruptly declared that it was about time to call for the engineer's resignation, and for a general cleaning-up of his department (the latter being a favorite phrase among some aldermen).

Inquiry was rewarded by the information that the engineer had taken suddenly ill and was removed to a health resort. Prior to his departure his deputies were carefully instructed in the matter of their work during his absence, and the department was experiencing no cessation of activities as the result of his personal misfortune. With the promise of his medical adviser to acquaint the Board of Works of his necessary suspension of duties, the engineer had obeyed the strict instructions, thereby occasioning the debate already referred to, in which more than one alderman is quoted to have endorsed the statement, "If a man in his position (the engineer's) goes away without our instructions and without our knowing when he is coming back, it is about time to call for his resignation."

The scene changes. More recent press reports state that during the comparatively short period of twelve months, six working months of 1911 and 1912, this engineer has established a record in development and improvement work in that city which has not been equalled in any other Canadian city, his record including over 32 miles of block pavement, over 56 miles of sewers, about 95 miles of cement sidewalks, some 74 to 80 miles of streets cleared and rough-graded, 30 to 40 miles of rocking, and about 90 miles of water mains, the aggregate cost of this gigantic achievement being in the neighborhood of $8,000,000. In addition to this successful endeavor, through bringing down recommendations for greater yardages of pavements than had hitherto been attempted, and thereby inducing keener competition, he saved the city something like $130,000, as compared with the cost of the pavements which had previously been put down.

The engineer was not fired, thanks to the discrepancies in the point-carrying ability of some individuals, but his discharge was under consideration without an appearance of good grounds.

The case is just another example of the absolute lack on the part of civic councils of the elementary principles of fairness in dealing with municipal officials. Other examples have been previously given in *The Canadian Engineer*. Each example endorses the opinion that city councils have outgrown their usefulness, that the qualifications which bring about the election of many of the members are far removed from those of knowledge and ability which the responsibilities of their positions warrant, and that so long as the present method of election is entertained, these governing bodies will not measure up to a much higher standard than the one that is being

referred to here. As already mentioned time and again in this journal, the trouble lies in the city councils and the remedy is there also.

It is against such contingencies as these that some municipal engineers are obliged to carry on a single-handed strife. It is very doubtful whether the existence and powers of a professional association on their behalf, to whose consideration they might refer such occurrences as these, would have much weight, considering the idiosyncrasies of many members of present-day municipal governing bodies.

ENGLISH FOR ENGINEERS.

Much has been written at one time and another about the utility of English as part of the engineering curriculum. *The Canadian Engineer* has always held that there is a need for some training for engineers along this line, in addition to that which the high school course supplies. Perhaps this need could not be better summed up than in the following paragraph, which we take the liberty of quoting from an article by Benjamin P. Kurtz in the California Journal of Technology:

"When facts of iron and steel, of girders and trusses, are turned into a written report, they are presented no longer in their own tangible, objective medium or material, but in the new and subjective medium of words. Now, in the first place, it is to be noted that in this passage from the realm of objective reality to written representation there is ever present the dangerous chance of deflection of facts and even of their actual transformation—in a word, the danger of error. This, merely because of the sudden transition to a new and unaccustomed medium. More narrowly regarded, however, the difficulty arising here is that of accuracy of statement plus the adaptation of technical facts and information to the laws and economy of mental attention. In order to gain and hold the attention of the reader, in order to present facts in such fashion that they may be easily and thoroughly understood, and that the general proposition may be seen to be supported at every point by its details, so that there is the mutual proof of a complete harmony between parts and the whole—in order to accomplish this successful communication with another mind, it at once becomes necessary to marshal the objective facts or material in such fashion that they will find a ready, orderly and emphatic entrance into the mind of the reader. Facts without grouping dissipate the attention; poor grouping, overlapping division, insufficiently marked separation confuse the attention; diffuse, wandering connections weary the attention; neglect to distinguish between division and implication, or between fact and hypothesis, muddle the conception of the reader; tortuous and nebulous sentences befog the conception of the writer; insufficient recognition of the necessity of exemplification and illustration, and ignorance of their difference, leave the reader too much to do or undo; the very lack of knowledge of what constitutes a definition, and of the fundamental methods of expanding a logical definition, lay the entire argument open to objection or render its outlines amorphous. In two words, the necessity of being understood, not the achievement of truth; the necessity of presenting groups of facts in accordance with the habits of trained thought-attention, not the accuracy of turning one fact into one phase;—this is that new labor and skill required of the technician when he expounds his facts and thoughts to other minds in the medium of words."

This very clearly states the newer conditions to be met. We regret that the value of what Mr. Kurtz calls "expository composition" has not been as fully recognized by the engineering faculties of some of our universities as to provide for a course in English of as great a length as can reasonably be expected in their already-crowded curriculums.

CANADIAN PUBLIC HEALTH ASSOCIATION.

The third annual congress of the Canadian Public Health Association will be held in Regina, Sask., on September 18th, 19th and 20, 1913.

The following papers will be presented at the sectional meeting of engineers and architects, of which Mr. L. A. Thornton, B.A., B.Sc., city commissioner of Regina, is chairman:—

(a) "Municipal Loans and Municipal Works," R. O. Wynne-Roberts, M. Inst. C.E., M. Can. Soc. C.E., consulting engineer, Regina.

(b) "Hygiene of School Buildings," J. H. Puntin, L.R., I.B.A., architect to the Regina School Board.

(c) "Results of Water Filtration at Saskatoon," Geo. T. Clark, B.A., A. M. Can. Soc. C.E., city engineer, Saskatoon.

(d) "Sanitary Surveys of Rivers," J. R. Malek, C.E., assistant sanitary engineer, Bureau of Public Health, Regina.

(e) "Sunlight in Cities," Theo. Brockmann, Dipl. Ingr. (Berlin), city engineer's office, Regina.

(f) "The Effect of Water Filtration—Biological and Chemical," H. W. Cowan, C.E., Toronto.

(g) Paper—title to be announced later—J. Antonisen, C.E., superintendent, Brandon Municipal Railway.

(h) "Canadian Conditions Affecting the Design, Construction and Operation of Sewage Disposal Works," R. H. Murray, A. M. Inst. C.E., A. M. Can. Soc. C.E., resident sanitary engineer, Bureau of Public Health, Regina.

In addition to the above, the following papers of particular interest to engineers will be presented at the general sessions:—

"The Smoke Problem," R. N. Blackburn, Wh.Sch., chief inspector of steam boilers for Saskatchewan.

"Standards With Reference to Sewage Treatment," T. Aird Murray, M. Can. Soc. C.E., consulting engineer, Toronto, Ont.

Engineers and public health officials intending to be present at the congress should notify the local secretary, R. H. Murray, C.E., Bureau of Public Health, Regina.

LETTER TO THE EDITOR.

A Question of Stability.

Sir,—The following account of how a large brick arch is standing at the present time, with parts of its abutments entirely cut away, is a very good illustration of the remark once made by a great engineer who, in response to a query as to why a certain structure stood up replied, "By the grace of God and the force of habit,"

and for this, if for no other reason, the following description should be of interest to all engineers and contractors.

Extensive alterations are being made to a church situated on the west side of the city of New York. These alterations, in so far as they have been carried out up to the present time, consist in entirely wrecking one wing of the church, in order to make way for a new addition. The wrecked wing was separated from the main body of the church by a 28-inch brick bearing-wall, which has been left in position, except as hereinafter described. Communication between the two parts of the edifice through this wall was by means of a large opening about 18 feet wide, spanned by a four-rowlock brick arch. This arch not only carries the 28-inch wall extending for about 15 feet above the crown of the arch, but also carries a small portion of the roof of the main part of the church.

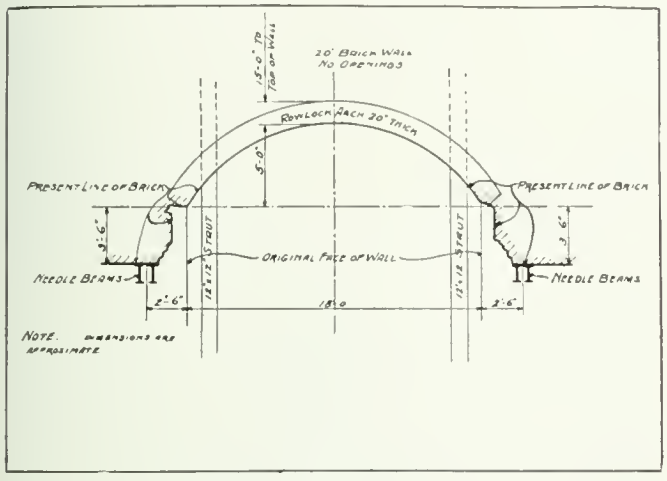

Fig. 1.

Part of the new work to be installed consists in placing steel columns in this wall, and in order to do this, the contractor has braced up part of the roof of the main building resting on the arch with long 12-in. by 12-in. strut timbers extending to the main floor of the church, has run needle beams through the wall at various points, two sets of which are shown in Fig. 1, and then has cut away the wall under the needle beams, and also under the ends of the brick arch. In Fig. 1, the original face of the wall is indicated, and the present line of the brickwork shown in a heavy line.

Why this arch stands, is something of a mystery, but the explanation, as far as any can be given, is as follows: The brickwork above the arch is acting as a false arch and, aided by the temporary struts supporting the roof, is carrying the load above, the true arch really being supported by this false arch, and the bricks of the arch are held in position solely by the adhesion of the mortar. It is a question in the writer's mind how far such a risk should be taken, with a span of this size, even with first-class brickwork. He strongly condemns this particular case, and, indeed, expects any day to pass by and find this arch in ruins. It is such work as this that, when a failure occurs, brings engineers and engineering into disrepute, although if the facts were known, it would probably be found that no engineer had anything whatever to do with this particular piece of work.

J. H. GANDOLFO,
Assoc. M. Am. Soc. C.E.

New York City, August 7, 1913.

CUTS IN NEWLY PAVED STREETS.

By James E. Barlow,
Assistant City Engineer, Cincinnati, Ohio.

THIS paper appears in the Proceedings of the American Road Builders' Association, and deals with the problem of underground services with which all cities have to contend. A cross section of a downtown city street shows car tracks, electric ducts, telephone conduits, water mains, gas mains, sewers, etc., and, of course, leading from these to the different buildings, are the necessary service branches. These all constitute a network which honeycombs pavement foundations, and it is the repair, renewal and extension of these which give rise to the problem which forms the subject of Mr. Barlow's paper.

It is a matter of common observation that an opening repaired is never as good as the original undisturbed pavement. In addition to the general disturbance of the subsoil there is usually left a slight hummock or a slight depression in the pavement which the pounding of traffic accentuates, causing a more or less endless chain of repairs. Eminent authorities have estimated that in some cities the useful life of the pavement is decreased 25 per cent. by these cuts. The reduction in the life of the pavement in a city such as Cincinnati is probably not as great as this, but nevertheless, the damage is very real. Some idea of this damage in dollars and cents may be had when one realizes that the cost of pavements, including maintenance, interest and renewals in a modern city like Cincinnati, exceeds $2,000,000 per year, i.e., if our pavements were laid and maintained by a public service corporation, a fair annual rental would exceed the figure mentioned. Now, aside from shortening the life of the pavement, these openings cause danger and annoyance to traffic, wear and tear to vehicles; they render cleaning more difficult, they are unsightly in themselves until repaired and they are costly to restore and they later become the source of additional repairs. Thus the importance of properly controlling such openings and reducing them to a minimum is really seen.

As a complete solution of this problem some have suggested subways or pipe galleries under the streets with laterals to property lines. Others have suggested subways under the sidewalks, necessitating double lines of mains. However, the investments tied up in the present form of underground construction, the enormous expense necessary for subways and the fact that much of the sidewalk space where subways are most needed is used privately for buildings as areaways, all tend to throw this solution, for most cities, into the somewhat distant future. The problem thus becomes one of best controlling the present cuts and reducing the number to a minimum.

When a street is to be improved notices of the two final steps in the legislation are sent to all the public service corporations, and again when bids are received, and again when the contractor is ordered to begin work. The object of these notices, of course, is to keep the companies informed of the status of the proposed improvement and allow them ample time to plan repairs, renewals or extensions. At the outset, however, it may as well be admitted that the franchises of these local public service corporations are such that we have little or no control over what they shall do along these lines.

As an additional lever, early this year a city ordinance was passed which virtually prevents any opening in a

newly laid pavement for a period of three years, except in regular emergencies. Notices calling attention to this ordinance are sent to all public service corporations and to property holders about three months before the actual work of construction begins.

The topography of Cincinnati is such that often the heavy cuts and fills practically prohibit the laying of mains until the street is graded. On all contacts now let, if the street does not already contain water and sewer mains, they are included in the street improvement contract. We only wish we might include gas in the same way.

To prevent, in so far as possible, openings for house connections, we are now serving notices on all property owners along a proposed improvement to make water and sewer connections to their lots, whether occupied or vacant. If these are not made in 20 days, the city makes such connections to the curb line and assesses the cost thereof against the individual property. This calls forth considerable objection, but it must be borne in mind that half the owners gladly make all connections and it is only just, that we should take such steps to prevent the other half from damaging the pavement.

The preceding may all be classed as preventive measures. There is also to be considered the proper control and restoration of the necessary openings.

An important step in an intelligent control of street openings is to know what you have under the pavements and where these structures are. This primary information is not always in the hands of cities. In connection with an investigation for a comprehensive sewer layout, a complete underground survey is being made to locate all of the subsurface structures. These plots will be made on a scale of 40 and 50 ft. to the inch. There will be possibly 1,000 sheets, 24 by 34 ins., in the complete set. When compiled these will be kept up-to-date as a basis for our underground records and we can then more intelligently direct future underground construction.

There is, of course, also to be considered the actual making of the restorations. Several years ago a city ordinance was passed making it unlawful for any person other than the street repair department to open any pavement without a permit therefor. This ordinance further provided that the application for this permit should state the location and size of the opening and the kind of pavement. Before the permit is issued a deposit is required, based on the published sliding scale of prices for the restoration of different sized openings in the various kinds of pavements. No persons other than the employees of the street repair department are allowed to permanently restore these openings.

The party making the opening does the backfilling and makes a temporary restoration of the pavement; if the backfilling is not properly done the street repair department does it over and bills it to the party responsible.

The street repair department handles the issuing of all permits and, of course, makes all rules in accordance with which such openings can be made. The control of the openings and the responsibility for their speedy and adequate restoration is thus centralized.

This outlines the principal steps taken here to control street openings. Some of these measures cause much friction and delay, especially those involving serving of legal notices which require definite periods of time before action can be taken. However, it is felt that the end justifies the means.

SIXTY-TON ELECTRIC CANTILEVER CRANE.

A large cantilever crane constructed for loading blocks for building the harbor at Valparaiso was described in a recent issue of Engineering (London). The crane lifts the full load of 60 tons at 52 ft. from the centre of the crane, and is intended for raising the blocks from the railway trucks and transporting them to a barge lying alongside the jetty. The load is carried on a travelling jenny, and the machine is fitted with three independent lifts—viz., one lift for the maximum load of 60 tons operated by a 40-brake-horse-power motor, and two separate lifting motions, each capable of dealing with loads of 7½ tons, and operated by two 20-brake-horse-power motors. This arrangement was fitted so that the crane could deal with tipping-skips, the intention being that the skip and its contents, weighing 15 tons, might be lifted by the two 7½-ton motions operating synchronously and tipped as desired by working them separately, each lift being fitted with an independent brake. The lifting barrels are capable of coiling sufficient rope to allow the hook to descend 25 ft. below the quay level. All the gear wheels, with the exception of the large barrel-wheel and pinion, are machine-cut from the solid. For the heavy lift there is a powerful solenoid brake, as well as rheostatic brakes, and a mechanical emergency brake is also fitted. The auxiliary brakes are fitted with both solenoid brakes and rheostatic brakes, and there is also a solenoid brake fitted to the reversing motion.

PEAT POWDER AS FUEL FOR LOCOMOTIVES.

A consular report announces that a Swedish engineer, has perfected a process for utilizing peat powder as fuel for locomotives. The news has awakened interest in the possibility of developing the extensive peat bogs of Sweden.

The powder is manufactured by the Ekelund process. A factory has been in operation for several years in Sweden, under the management of the inventor of the powder process. It does not appear that the Ekelund process has made much headway as yet, but it is now predicted that in connection with the new discovery, the use of peat powder will in time become extensive.

In this system the peat powder is fed by an automatic process into the furnace of the locomotive, which is especially arranged to consume it. The Ekelund process is on the market in various countries, including the United States, but little has been made public concerning the new method. According to Mr. Von Porat, the inventor, the results obtained with peat powder may be summed up as follows:—

Substantially the same results can be had from 1½ tons of peat powder that one ton of coal will produce. Peat powder may be burned with an admixture of about 5 per cent. of coal. As to firing with peat powder, the work is almost nothing in comparison with firing with coal, because the powder is forced into the furnace by automatic process. No change had to be made in the boiler and none in the firebox, except installing the special apparatus. There is no difficulty in bringing the powder from the tender to the firebox, as it passes through a conveyance pipe. Another advantage in using peat powder is that no cold air can get into the firebox and neither smoke nor sparks escape from the smoke-stack.

As a result of engineer Von Porat's invention, it is reported that a number of the Swedish railways are preparing to use peat powder instead of coal.

MECHANICAL HANDLING OF MATERIALS

CLASSIFICATION OF APPARATUS — FLIGHT CONVEYERS — THE FIRST OF A SERIES OF ARTICLES ON INSTALLATION, MAINTENANCE AND OPERATION OF CONVEYING MACHINERY.

By REGINALD TRAUTSCHOLD, M.E.

CONVEYING and elevating machinery, though indispensable in almost any modern industrial operation or enterprise, is of comparatively recent development; the manufacture of such apparatus not commencing much before the beginning of the last quarter of the nineteenth century. To-day, fuel for the power house, the disposal of ashes, the handling of materials in cement mills and of ores at the mines and smelters, etc., raw materials to and through mills and factories, the handling of finished products, distribution of merchandise, dredging and excavating operations of all kinds, etc., etc., all require some kind of conveyer or elevator if such operations are to be performed with the economy and efficiency demanded by modern conditions. Though apparatus for the mechanical handling of materials is comparatively new, much progress has been made in this branch during the past twenty years or so and the requirements for power, capacity, etc., and the cost of operation, of equipment, etc., are now pretty well standardized, and it will be the aim of this discussion to describe the more common types of conveying and elevating machinery with such data as will permit a conservative and reliable opinion to be formed as to the economic value of each class of apparatus. Tables, charts and formulæ will be interposed wherever practical and illustrations of typical installations inserted throughout the text. The tables and charts, giving costs of apparatus, operation, maintenance, etc., will be conservative and refer to *good practice* in the Dominion. Their reliability will therefore depend on the proper care and attention to all machinery, for the results attainable can only be realized with apparatus that is not subject to abuse or neglect.

Conveying machinery may for convenience be distinguished from elevating machinery by considering the first to include all apparatus for carrying material along a horizontal plane or raising it from one plane to another through a comparatively gradual incline, and the second all apparatus that elevates material in a vertical plane or raises it through a comparatively steep incline. Naturally these two classes cannot be rigidly adhered to for much machinery for the mechanical handling of materials performs both operations of conveying and elevating. However, the division will facilitate a comprehensive discussion. Conveying machinery may be again subdivided into three general classes: 1st, apparatus that pushes or pulls the load, the moving parts not carrying the weight of the load; 2nd, apparatus that carries the load on moving parts; and 3rd, conveyers which depend for their operation on other than mechanical forces. Elevating machinery is classified in only the two last subdivisions for elevating operations by apparatus that drags or pushes the load are performed by conveyers at comparatively slight inclination, pumps not being considered in this discussion of mechanical handling of materials.

Flight (Scraper) Conveyers.—The oldest type of conveyer and one that is in common use to-day, in somewhat modernized form, consists of an endless chain to which are attached at intervals plates, or flights, which scrape the material handled along a trough in which are gates through which the load is discharged where desired. These conveyers may have simply one chain attached at the centre of the flight or else have two chains, one attached to each end of the flight. In the latter type of flight conveyer—double chain conveyer—the flights are usually equipped with wearing shoes that slide along guides on the sides of the conveyer and carry the weight of the moving parts preventing the flights themselves from coming in contact with and dragging along the trough, or else the flights are furnished with small wheels, or rollers, that run on rails or guides on the sides of the trough and perform the same functions as the shoes in the cruder type. Naturally the roller flight conveyer consumes rather less power than does a shoe flight conveyer under similar service, but the roller flight conveyer is somewhat more expensive. The balance of apparatus required for a flight conveyer consists simply of the trough, which is usually of steel, or some other material that will resist abrasive wear or of wood lined with a suitable wear-resisting metal; sprockets over which the conveyer chain runs; suitable driving mechanism, consisting usually of a system of gears by means of which the speed of the power unit is reduced to the proper amount; the gates and chutes through which the material is discharged from the conveyer, and chutes for loading the conveyer.

Three conditions govern the capacity of flight conveyers—the weight of the material to be conveyed being neglected—1st, the speed at which the conveyer is run; 2nd, the area of the flights presented against the material dragged along the trough; and 3rd, the distance between flights (intervals). The advisable speed of conveyer depends largely upon the nature of the material to be conveyed and may be anywhere from 100 to 200 feet per minute. The flights are usually rectangular in shape with a length (slightly less than the width of the trough) about three times as great as their width (the dimension at right angles to the plane of the trough) and are spaced from one to two feet apart. Two other conditions effect the capacity of this type of conveyer, however, which depend upon the nature of the material conveyed more than upon the conveyer itself. They are, the weight of the material and its angle of repose. The first effects the capacity of the conveyer directly; that is, the capacity of a given conveyer at a given speed varies directly with the weight of the material handled. The second condition has little effect on horizontal conveyers—the angle of repose of the average class of material handled by flight conveyers not varying to any very great extent—but does effect the capacity of inclined conveyers. For all practical purposes, however, the reduction in capacity of an inclined flight conveyer depends directly upon the inclination of the conveyer. For instance, the capacity of a flight conveyer inclined 10 degrees to the horizontal is but about 80 per cent. of that of a similar horizontal conveyer; a conveyer inclined 20 degrees, about 66 per cent.; while a flight con-

veyer, inclined 30 degrees to the horizontal, about the limiting inclination for such a conveyer, would have a capacity about one-half as great as that of a conveyer running in a horizontal plane. Flight conveyers carrying a load from one elevation to a lower one has increased carrying capacity, the limit being that point at which the angle of repose of the material is equal to the angle of declination. These latter conveyers, those running down hill, are so rare, however, that they may be overlooked in this discussion, any such installation being quite special and presenting a distinct engineering problem. Flight conveyers, though depending directly upon the weight of the material handled for their capacity, should not always be run at the same speed nor is there any other rule but experience for ascertaining the most advisable speed of conveyer. Efficient speeds for certain materials handled by this type of conveyer are given in Table I., together with the average weight of such materials per cubic foot. Table II. gives the capacity of some of the common sizes (width x length of flights) of horizontal flight conveyers carrying material weighing 100 pounds per cubic foot at a speed of 100 feet per minute, conveyer being uniformly and continuously loaded. The capacity of similar conveyers carrying material of other weight and at different speed varies directly with both the weight and speed. For instance, a conveyer carrying material weighing 50 pounds per cubic foot at a speed of 200 feet per minute would have a capacity the same at that given in Table II., conveyer handling material weighing 100 pounds at a speed of 100 feet per minute. Inclined conveyers have their capacity reduced from 1⅔ to 2 per cent. for each degree of angle of inclination. The approximate capacity of any flight conveyer may also be ascertained through the use of formulæ. (See Formulæ I. and II.).

Table I.—Economic Speeds of Flight Conveyers for Various Materials.

Material	Weight per cubic foot	Advisable Speed
Coke	32 to 35 pounds	100 ft. per min.
Broken Stone (course)	160 to 170 pounds	125 "
Lump Coal—R/M	50 to 60 pounds	125 "
Ashes	About 45 pounds	150 "
Lime and Cement	50 to 80 pounds	150 "
Ore	About 125 pounds	175 "
Crushed Stone	150 to 170 pounds	175 "
Sand and Gravel	100 to 120 pounds	175 "
Fine Coal	About 50 pounds	200 "

Table II.—Capacity of Flight or Scraper Conveyers.

Horizontal Conveyers.

Capacity in tons per hour at a conveyer speed of 100 feet per minute. Material weighing 100 pounds per cubic foot.

Size of Flights	Flights Spaced			
	12"	16"	18"	24"
4" x 10"	90	67	60	45
4" x 12"	114	85	76	57
5" x 12"	138	103	92	69
5" x 15"	186	139	124	93

8" x 18"	360	270	240	180
8" x 20"	420	315	280	210
8" x 24"	540	405	360	270

$$W_h = \frac{0.0002443\ AVw'}{S} \qquad \text{Formula I.}$$

$$W_i = W_h - \frac{0.016285\ L'W_h}{S} \qquad \text{Formula II.}$$

Where:—

W_h = Weight of maximum load in tons per hour—Horizontal Conveyer.

W_i = Weight of maximum load in tons per hour—Inclined Conveyer.

V = Velocity (speed) of Conveyer in feet per minute.

A = Area of Flights in square inches (width x length).

S = Spacing of Flights (intervals) in feet.

W' = Weight of material conveyed in pounds per cubic foot.

L' = Inclination of Conveyer in degrees—Inclined Conveyer.

The consumption of power in running a flight conveyer or any other similar piece of mechanism may be divided into that required to run the conveyer itself and that required to drag the load. In the case of flight conveyers, however, the latter operation is so much more severe that the power required to run the empty conveyer is but a comparatively small percentage of that required to run one fully loaded. The power required for moving the load depends upon the load handled and is relatively so great, compared with the requirements of the unloaded conveyer, that the latter may be taken, for all practical purposes, as also depending upon the load handled. This simplification of the power question has led certain manufacturers of such equipment customarily to figure the power requirements of conveyers with shoe flights and those with roller flights as identical. These two refinements of the old-fashioned drag conveyer have considerably reduced the power consumption of such conveyers, one to an appreciably greater extent than the other, however, and this fact is taken into account in the derivation of the following formula for ascertaining the horse-power required properly to drive a flight conveyer that is continuously and uniformly loaded—Formula III. Conveyers without shoe or roller flights are now limited to small sizes and to those that are relatively short, so that, while Formula III. is not exactly applicable to such conveyers, the error (lack of power) is so slight that the formula may be used by making an allowance of small percentage in cases of conveyers without the refinements of shoes or rollers. In fact, the choice of the power unit depends so largely upon the sizes of standard motors, engines, etc., that the most convenient size of power unit has usually an abundance of power to care for the slight error. For instance, a conveyer requiring 8½ horse-power would probably be equipped with a 10 horse-power motor which would have a capacity more than sufficient to care for any additional power required. The use of Chart I., which of necessity cannot be read as accurately as the results attainable by the use of the formula, will obviate the necessity of making any such corrections, the chart readings being sufficiently conservative to cover any small error.

Horsepower:—

W = Weight of load conveyed in tons per hour.

V = Velocity (speed) of Conveyer in feet per minute.

H = Height to which load is elevated in feet.

W_c = Weight of moving parts of Conveyer in pounds per foot. (average) = 0.74 W—Conveyers with shoe flights.
0.92 W—Conveyers with roller flights.

W' = Weight of load conveyed per minute per foot in pounds $= \frac{33W}{V}$

f_s = Speed factor = 0.18—from experiment—shoe flights.
= 0.09—from experiment—roller flights.

f_l = Load factor = 0.7—from experiment.

Horsepower required to run Conveyer empty.

$$HP = \frac{\left.\begin{matrix}0.74\ W\\0.92\ W\end{matrix}\right\} \times \frac{33W}{V} \times \left.\begin{matrix}0.18\\0.09\end{matrix}\right\} \times V \times L}{33000}$$

$$= \frac{0.1332\ WL}{1000}$$ (Conveyers with shoe flights.)

$$= \frac{0.0828\ WL}{1000}$$ (Conveyers with roller flights.)

Total horsepower required.

$$HP = \frac{C\ WL}{1000} + \frac{WH}{1000}$$ Formula III.

Where:—

C = Constant = 0.8332—Conveyers with shoe flights.
= 0.7828—Conveyers with roller flights.

Horsepower required to convey load.

$$HP = \frac{W \times 0.7 \times V \times L}{33000} = \frac{0.7\ WL}{1000}$$

Horsepower required to elevate load.

$$HP = \frac{W \times V \times H}{33000} = \frac{WH}{1000}$$

As the total weight of a well designed and proportioned flight conveyer bears a close relationship to its capacity, and as the cost of such a conveyer also varies nearly directly with the weight of the apparatus, it is possible to form a very close approximation of the cost of the ordinary flight conveyer in terms of its capacity; that

is, in terms of size and length of conveyer. The area of the flights governs largely the capacity of any flight conveyer, the strength of the chains required, sizes of sprockets, power of drive, etc., and consequently governs the cost of these component parts. The load handled by a particular size of conveyer naturally has some bearing on the strength of the individual parts, etc., but not so much as would be supposed; standardization of apparatus and economies of manufacture fixing pretty closely the size of chain, weight of flights, thickness of trough, etc., for any conveyer of particular size, irrespective of the actual requirements for strength. Hence, a formula that is applicable to nearly every installation of flight conveyers, giving results that may be considered as accurate

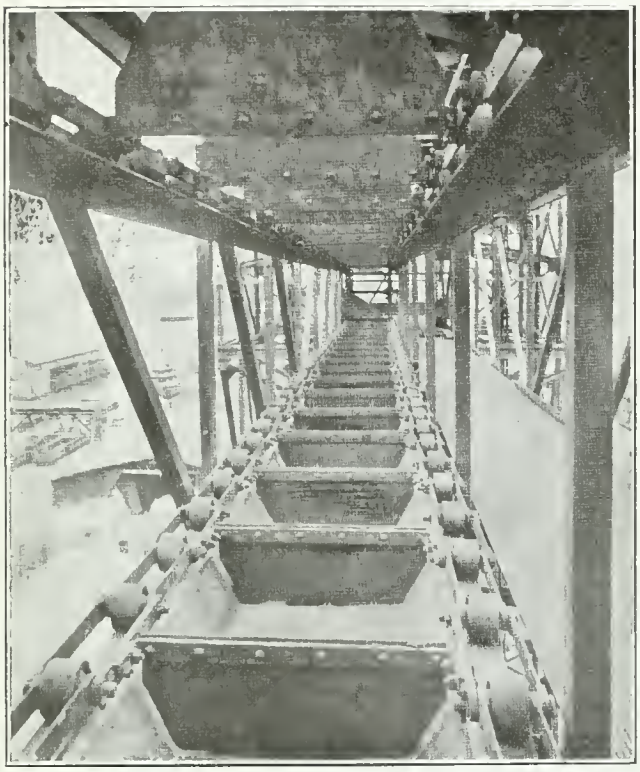

Fig. 1.—100-ton-per-hour Flight Conveyer, 360 Feet in Length, Used by the Philadelphia Rapid Transit Co.

for figuring the cost of operation of such equipment, may be derived which will give approximately accurate results for the cost of equipment, expressed in terms of size and length of conveyer—such a formula follows—Formula IV.

Cost of Equipment.

C = Cost of Flight Conveyer in dollars.
A = Area of flights in square inches—width x length.
L = Length of Conveyer in feet.

SINGLE CHAIN CONVEYER

Average cost of chains	$0.00066\ AL$
flights (roller) ..	$(0.00568\ A+3.0)L$
(shoe)....	$(0.00568\ A+1.5)L$
sprockets, drive, &c.	$6.0\sqrt{A}$
trough and rails, &c.	$(0.0413\sqrt{A}+0.0039\ A)L$
gates, &c.	$(0.01033\sqrt{A}+0.00089\ A)L$

ADDITIONAL—DOUBLE CHAIN CONVEYER

Chain Attachments, &c.	$0.000163\ AL$
Sprockets, &c.	$1.0\sqrt{A}$

Then :—

$$C = (DA+0.05163\sqrt{A}+E)L+F\sqrt{A} \qquad \text{Formula IV.}$$

Where :—

D = Constant = 0.01113—Single Chain Conveyer.
= 0.011293—Double Chain Conveyer.
E = Constant = 3.0—Conveyers with roller flights.
= 1.5—Conveyers with shoe flights.
F = Constant = 6.0—Single Chain Conveyer.
= 7.0—Double Chain Conveyer.

The cost of equipment as given by Formula IV., covers the cost of erection of a simple installation, but, if very special structures are required for support, etc., they should be figured upon separately and charged to the cost of equipment. Such extra expense is, however, frequently an item that can be charged to general plant equipment and construction, so, for practical purposes, Formula IV. may be considered as covering all such initial expenses as are chargeable to the conveyer installation. The average materials handled by such a conveyer do not vary (in respect to weight) to any very great extent, so that it is also possible to express the cost of the average flight conveyer equipment in terms of tonnage capacity; that is, the cost of equipment at so much per ton carrying capacity. Fixed charges of interest on investment, insurance, taxes, etc., chargeable to the yearly cost of operation, can be proportioned to the tonnage actually handled. Depreciation, renewals and repairs vary considerably for the component parts of the equipment, but all these items are pretty well known, in the case of the average conveyer subjected to proper attention and in operation a reasonable number of hours each day, so that an average yearly charge per ton capacity of conveyer can be arrived at. The question of power consumption depends directly upon tonnage handled and, knowing the cost of a horse-power, a charge per ton handled is easily figured. Labor, or attendance, supplies, etc., depend largely upon the use of the conveyer and, like power, can be charged to the tonnage handled. These various relationships permit the derivation of a formula for ascertaining the average net cost of operation of a flight conveyer per ton handled, consisting of two general items, the fixed charges per year and the expenses entailed during the hours of operation of the conveyer, divided by the total number of hours the conveyer is in actual operation during the year. See Formula V.

Net Cost of Operation—Net Operating Cost (N.O.C.).

W = Weight of load conveyed in tons per hour. (Capacity.)
L = Length of Conveyer in feet.
H = Height (distance) through which load is elevated in feet.
N = Number of hours (total) Conveyer is in use per year.
P_e = Price (cost) of a horsepower per hour in dollars.

Average cost of equipment :—
= 0.0146 WL + 0.75 W—Single Chain Conveyer.
= 0.0147 WL + 0.85 W—Double Chain Conveyer.

Fixed charges :—

Interest —6% total cost Insurance—1% Taxes —2%—¾ cost	=	Single Chain Conveyer 0.0012410 WL + 0.06375 W Double Chain Conveyer 0.0012495 WL + 0.07225 W

Depreciations, renewals, &c. :—

SINGLE CHAIN CONVEYER.
= 0.0035 WL + 0.0807 W—Conveyers with roller flights.
= 0.0040 WL + 0.0807 W—Conveyers with shoe flights.

DOUBLE CHAIN CONVEYER.
= 0.0037 WL + 0.0922 W—Conveyers with roller flights.
= 0.0038 WL + 0.0922 W—Conveyers with shoe flights.

Horsepower, attendance, supplies, etc. :—

HORIZONTAL CONVEYERS.

Cost of Power :—
= 0.0007828 WLNP_e — Conveyer with roller flights.
= 0.0008332 WLNP_e — Conveyer with shoe flights.
Cost of labor or attendance :—
= 0.000025 WLN — average.
Cost of supplies, &c. :—
= 0.0000676 WLN — Conveyers with roller flights.
= 0.0000909 WLN — Conveyers with shoe flights.

INCLINED CONVEYERS.

Cost of extra power :— = 0.00101 WHNP_e — average.
Cost of extra labor, &c. :—Negligible.
Cost of extra supplies, &c. :— = 0.0000133 WHN — average.

Then :—

$$\text{N.O.C.} = \frac{AL + B + CLN + 1.33\,HN + (DL + 101\,H)\,NP_e}{100{,}000\,N} \qquad \text{Formula V.}$$

Where :—

A = Constant = 474.10 — Single Chain Conveyer—roller flights.
= 524.10 — Single Chain Conveyer—shoe flights.
= 494.95 — Double Chain Conveyer—roller flights.
= 504.95 — Double Chain Conveyer—shoe flights.

B = Constant = 14445 — Single Chain Conveyer.
= 16447 — Double Chain Conveyer.

C = Constant = 9.26 — Conveyers with roller flights.
= 11.59 — Conveyers with shoe flights.

D = Constant = 78.28 — Conveyers with roller flights.
= 83.32 — Conveyers with shoe flights.

Examples.

Conditions :—

Length of Conveyer....	100′ 0″	= L
Material elevated	20′ 0″	= H
Service.....	2400 hours per year	= N
Cost of power.....	$0.02 per horsepower per hour	= P_e

Single Chain, roller flight, Conveyer.

$$\text{N.O.C.} = \frac{47410 + 14445 + 2222400 + 63840 + 472704}{240000000} = \$0.01175 \text{ per ton.}$$

Single Chain, shoe flight, Conveyer.

$$\text{N.O.C.} = \frac{52110 + 14445 + 2781600 + 63840 + 496896}{240000000} = \$0.01421 \text{ per ton.}$$

Double Chain, roller flight, Conveyer.

$$\text{N.O.C.} = \frac{49495 + 16447 + 2222400 + 63840 + 472704}{240000000} = \$0.01176 \text{ per ton.}$$

Double Chain, shoe flight, Conveyer.

$$\text{N.O.C.} = \frac{50495 + 16447 + 2781600 + 63840 + 496896}{240000000} = \$0.01421 \text{ per ton.}$$

Conditions :—

Same as in preceding example except that service is but 1200 hours per year.

Single Chain, roller flight, Conveyer.

$$\text{N.O.C.} = \frac{47410 + 14445 + 1111200 + 31920 + 236352}{120000000} = \$0.01201 \text{ per ton.}$$

Single Chain, shoe flight, Conveyer.

$$\text{N.O.C.} = \frac{52410 + 14445 + 1390800 + 31920 + 248448}{120000000} = \$0.01448 \text{ per ton.}$$

Double Chain, roller flight, Conveyer.

$$\text{N.O.C.} = \frac{49495 + 16447 + 1111200 + 31920 + 236352}{120000000} = \$0.01204 \text{ per ton.}$$

Double Chain, shoe flight, Conveyer.

$$\text{N.O.C.} = \frac{50495 + 16447 + 1390800 + 31920 + 248448}{120000000} = \$0.01448 \text{ per ton.}$$

The use of Formula V. gives results that agree very closely with those attained in ordinary good practice, and it is interesting to note that the economic value of the conveyer does not vary greatly with service, if subjected to reasonable usage. In the examples cited—the conditions of which are common in practice—there is only a difference of less than 2½ per cent. between the net cost of operation when using the conveyer 2,400 hours per year and 1,200 hours. Of course, much less than 1,200 hours' operation per year would materially increase the net cost of handling the material but the value of an installation of which such slight service only is required would be problematic. Another point of interest is that there is practically no difference in the net cost of operation of a one-chain or a two-chain conveyer—indicating the correctness or accuracy of the formulæ—although the refinement of roller flights does considerably reduce the cost of handling, the reduction of about 17 per cent. indicated by the formulæ being confirmed in practice as a fair record of the difference in actual operating costs of the two types of flight conveyers. The choice between a one and a two-chain conveyer is governed almost exclusively by the size of the conveyer—the larger conveyers usually having two chains. Severe conditions, however, under which operation must be performed sometimes makes it advisable to equip even the small sizes of conveyers with the two chains. In such a case, the initial cost of equipment would be somewhat increased in order to obtain satisfactory wear and operation of the conveyer and Formula V. would be applicable even under such conditions.

The foregoing discussion has been limited to the ordinary type of flight conveyer as found in the average mine or industrial plant, but many other adaptations and modifications of this standard type of conveyer are in common use; such as log hauls, ice conveyers and crude drag conveyers of all descriptions, which present many problems that require individual solution that cannot be taken up in the present discussion. The problems presented in these special cases are not, however, difficult of solution and modifications of the formulæ that have been given will be found to meet the requirements of almost any installation of flight or drag conveyers.

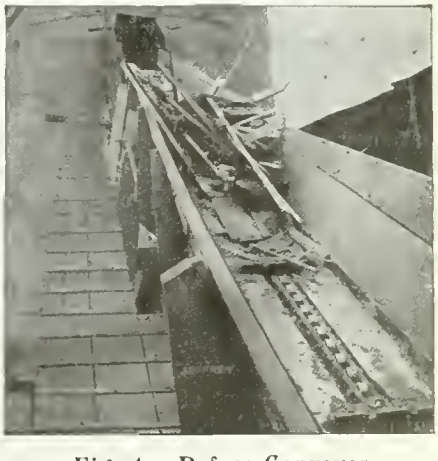

Fig. 4.—Refuse Conveyer.

Drainage work in Manitoba made good progress during 1912, according to the report of the Department of Public Works for the fiscal year ending November 30th, 1912. At that date 1,844.8 miles of drains had been constructed, benefiting in the neighborhood of 1,984,000 acres.

THE BOUCANNE RIVER VIADUCT

GENERAL FEATURES OF THE DESIGN OF THIS NATIONAL TRANSCONTINENTAL RAILWAY VIADUCT—OUT-OF-THE-ORDINARY METHODS OF ERECTION — PAPER PREPARED FOR INSTITUTION OF CIVIL ENGINEERS, GREAT BRITAIN.

By P. L. PRATLEY, M.E., Assoc. M. Inst. C.E.
Designing Engineer, Dominion Bridge Co., Limited, Montreal

THE National Transcontinental Railway crosses the Boucanne River at a point 167.2 miles east of the Quebec Bridge, which is the St. Lawrence River crossing of the same line. Both crossings are situated in the province of Quebec, in the B district of the eastern division of the railway.

The Boucanne River crossing occurs just north of the peak of Maine, where this State geographically juts into British territory. Although the river at this point is but a shallow stream with a depth varying with the seasons from a few inches to 5 feet, and a width of about 100 feet, the valley in which it flows is quite a considerable depression. These conditions, together with the fact that the line follows generally the the "height of land," necessitate a crossing 790 feet in length, with a maximum height of 127 feet from the base of the rails to water-level. The viaduct is of the trestle type, and as indicated by the general outline in Fig. 1, it consists of five towers of 30 feet span and two of 40 feet, with intermediate spans of various lengths.

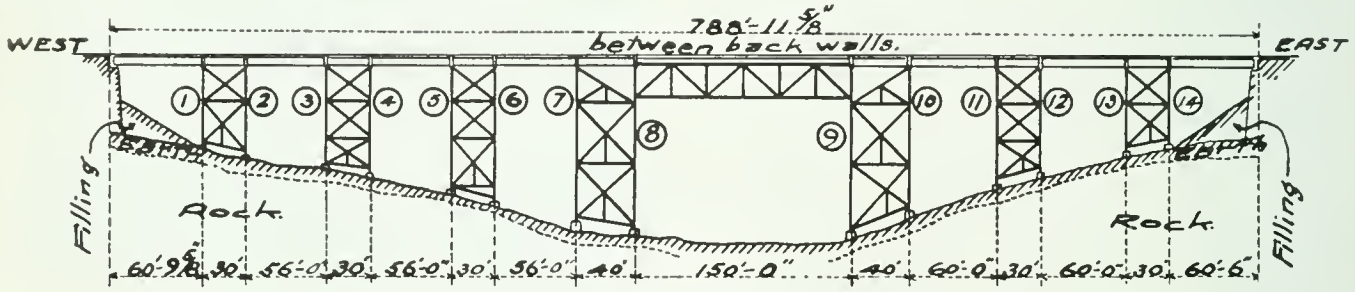

Fig. 1.—General Outline of Viaduct.

The viaduct is perfectly straight, except for about 135 feet at the west end, where it lies on the approach spiral to a 6° curve (radius 977 feet), which commences 165 feet west of the bridge. The transition spiral is thus 300 feet long, and is laid out as a cubic parabola with the equation $y = kx^3$, y being the offset from the tangent, x the distance from the beginning of the spiral measured along it, and k a constant, in this case equal to 0.00000058232; so that at the end of the transition spiral, where $x = 300$, $y = 15.72$ feet.

The viaduct is of the deck type, that is, the track is laid on cross timbers or "ties" placed with 4-inch spaced between them. The ties are 10 inches wide by 12 inches deep, and are generally 14 feet long, "dapped" ½ inch over the top flanges of the girders, and held in place longitudinally by timbers running along the ends of the ties and "dapped" over them. The girders are 9 feet apart between centres, and are uniformly 6 feet deep. The transverse batter of the towers is 1 in 6, and this, together with the depth of the truss and its detail, brings the width of the truss span to 17 feet 2¼ inches between centres. The viaduct is also on a gradient of 1.10 per cent. (1 in 90), falling toward the east. The gradient is, of course, affected by the vertical spiral at the west end whereby the superelevation of the 6° curve is gradually attained, but not to any larger extent than can be adjusted by the size of the ties used on the end span. The necessary tilting of the track on the bridge is also small enough to be effected in the ties.

The ground at the side is principally earth and boulders, with solid rock about 10 feet below, so that the concrete pedestals and abutment-walls were well founded on the bed rock.

Points in the Design.—The viaduct is designed in accordance with the specifications issued by the Dominion Government in 1908, with one or two further restrictions imposed by the bridge-engineers of the National Transcontinental Railway, which will be specifically alluded to later. The steel was proportioned for a live load known as Class "Heavy." This consists of two engines with tenders, the whole weighing 180 (short) tons, on a combined wheel-base of 104 feet, followed by a uniform train-load of 4,750 lbs. per lineal foot of track. This uniform load can be obtained with a train of heavy steel wagons weighing up to 30 or 35 tons each, and each carrying up to 60 tons of coal, their length being 36 to 40 feet over the couplings. The maximum axle-load on the driving-wheels of the locomotive in this class is 49,400 lbs.

The specification calls for an extra allowance of load for impact equal to the figure obtained by dividing the square of the live load by the sum of the dead and live loads. In addition to this, for all spans of less than 80 feet, including the stringers and cross floor-beams of the truss span, the live load itself is increased by a percentage which depends upon the length of the span, having a maximum of 40 per cent. at the theoretical span of zero, diminishing according to the formula $0.40 - \frac{l}{200}$, where l is the length of the span in feet, and vanishing at 80 feet. In the Transcontinental Railway bridges this increment of live load is introduced into the live-load figure used in the impact formula, as well as into the pure live load, so that for the girders of the Boucanne River Viaduct the impact load was obtained by dividing the square of the increased live load by the sum of the increased live

load and the dead load. The sum of the dead load, the increased live load, and the impact, thus obtained, is treated as the total load both for shear and bending moments. For this load a unit shear of 10,000 lbs. per square inch is allowed on the gross section of the webs of plate-web girders; and on the net section of the tension flange a unit fibre-stress of 16,000 lbs. per square inch is permitted.

Fig. 2.—View of the Completed Viaduct.

The gross area of the compression flange is made equal to the gross area of the tension flange, and 75 per cent. of the gross bending value of the web-plate is considered as effectively assisting the flanges to resist the induced bending-moments.

Under these specifications the weight of steel in the 60-foot deck plate-girder spans is 57,000 lbs. per span, including both girders and all wind- and sway-bracing. In the 56-foot spans the corresponding weight was 51,000 lbs., in the 40-foot spans 29,000 lbs., and in the 30-foot spans 17,500 lbs. per span.

The principal object of this paper is to describe the methods employed in the erection of the larger towers and the truss span. The trusses of the 150-foot span, as will be seen from Figs. 1 and 3, have six panels of 25 feet, are in vertical planes, measure 25 feet deep between the centres of gravity of the chords, and are of the Warren type. The cross girders or floor-beams at the intermediate panels are 4 feet 4¼ inches deep over the flange-angles and are riveted to the vertical members of the truss just under the top chord. The end floor-beams, which have to support the 40-foot girder spans, are 5 feet ¼ inch deep over the flange-angles, and are 1 foot lower on the truss than the intermediate beams, in order to allow for the difference in depth between the 40-foot girders mentioned and the stringers of the truss span. The latter are also plate-web girders, their depth thus being 5 feet ¼ inch from back to back of the angles against the uniform 6 feet ¼ inch of the girder spans. It will thus be seen that the stringer girders sit on top of the floor-beams and are 9 feet apart between centres, being in fact 25-foot deck plate-girder spans. The floor-beams are similarly single-web plate girders with webs 7/16 inch thick and flange-angles 6 inches by 6 inches by 9/16 inch in the deeper and 6 inches by 6 inches by ⅝ inch in the shallower. The material in the top chord is ½ inch throughout, while both angles and plates in the bottom chord are 7/16 inch in thickness in the first two panels at each end and ¾ inch thick in the two central panels. The web system of vertical and diagonal members is consistently of H shape, the plate being ⅜ inch thick, except in the compression diagonals, where ½-inch plate is used. The angles are 9-inch by 3½-inch by ½-inch bulb angles in all the diagonals and the end verticals, whilst in the verticals that are merely hangers they are 6-inch by 3½-inch by ⅜-inch angles, and in the intermediate compression verticals 7-inch by 3½-inch by ⅝-inch angles. The main or end compression diagonal is further reinforced by 19-inch by ¾-inch plates on the outside of each pair of bulb angles.

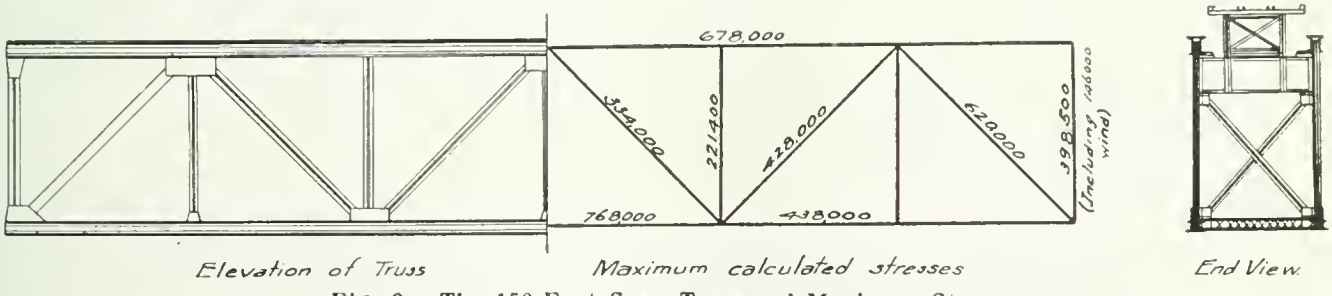

Fig. 3.—The 150-Foot Span Truss and Maximum Stresses.

The impact-formula explained above will be seen to be based on two main assumptions. The first is that the greater the dead load of a span of given length, the less will be the dynamic effect of the sudden application of the live load. For example, a pony-truss span carrying a ballast and concrete floor would suffer less impact load than girders carrying the usual timber deck. The second assumption is that the longer a span, the less likely is the maximum dynamic effect to occur with the maximum live load. The shorter the span, the more suddenly will the live load reach the maximum and the more severe will be the vibratory effects of unbalanced engine-wheels and jumping loads. On the other hand, the longer the span the more gradually does the induced stress attain its maximum, and the more generally distributed will be the effect of impinging loads.

The maximum stress in the top chord, composed of dead load, live load and impact load, amounts to 678,000 lbs., for which a section of 50.5 square inches is provided, the maximum unit compression allowed by the engineers of the Transcontinental Railway being 13,600 lbs. per square inch. This figure is an arbitrary restriction on the government specification, which would permit 14,600 lbs., the formula followed being $16{,}000 \div \left(1 + \frac{l^2}{18{,}000\, r^2}\right)$, assuming fixed ends.

The bottom chord receives a possible maximum stress of 768,000 lbs., which at 16,000 lbs. per square inch requires 48 square inches of net sectional area. To meet this 48.76 square inches is supplied, being the effective net section obtained from the 60.76 square inches gross

section provided. The Transcontinental Railway also prescribes that the Government formula for free-ended compression members shall be used for their vertical struts, whilst for the compression diagonals the intermediate formula $16{,}000 \div 1 + \frac{l^2}{12{,}000\, r^2}$ is used, the constant before r^2 being 9,000 for free ends. By this means the units indicated in Fig. 3 are obtained, and by their aid the necessary cross section is calculated. The tension unit is 16,000 lbs. per square inch throughout.

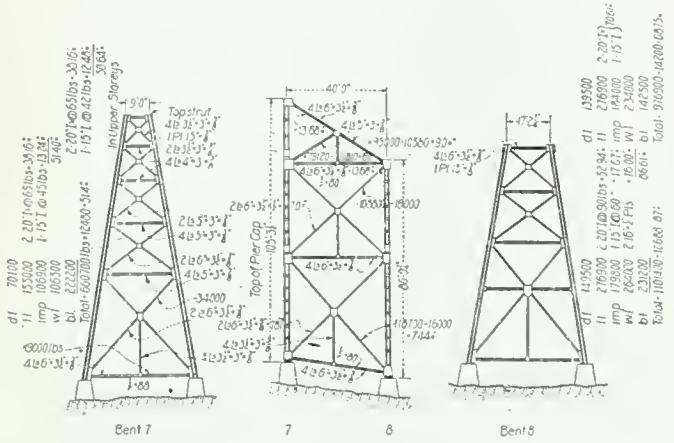

Fig. 4.—Typical Compression Stresses.

The trusses are braced together horizontally by both top and bottom lateral systems, the top consisting of crossed single diagonal angles in each panel, connected to the underside of the chord-angles and to the bottom flange of the stringers. The bottom lateral bracing consists of transverse horizontal struts of four angles laced in pairs and of cross diagonals similarly constructed. They are made the full depth of the chord, for the sake of simplicity and efficiency in connection. Undtr each floor-beam there is a sway-brace consisting of cross diagonals connected to the vertical members of the trusses and to the bottom struts.

An interesting feature of the specification, perhaps, is the clause governing the dimensions of the lattice bars. The lower side of the top chord is, of course, latticed between gusset-plates, and here 5½-inch by 9/16-inch single lacing is used. The bottom chord is laced in both its upper and lower faces with 3-inch by ½-inch double lacing, whilst the lacing of all the lateral struts and diagonals is 2½ inches by ⅜ inch. The specification requires that the thickness of the bars shall be at least 1/40 of the distance between the rivets that connect their ends to the two leaves of the members which they lace, if singly laced, and 1/60 of that distance if doubly laced. On the upper chord, the web-plates being 14¼ inches apart, the gauge-lines on the angles are 20¼ inches, which with approximately 60° lacing gives 23 inches between rivets and 23/40 inch or 0.575 inch as the required thickness, for which 9/16 inch was used. The width is governed by the fact that two rivets were required at each end, and these could not be obtained with the necessary edge distances on the lattice bar under 5½ inches. Similarly on the bottom chord, the same 20½ inches with 45° lacing gives 28½ inches between end rivets and calls for bars 28.5 inches

$\frac{28.5}{60}$ or 0.48 inch in thickness. One rivet being sufficient connection, a 3-inch bar was adopted here. The latticing in the bracing members need only be made 75 per cent. as heavy as the above specification, and so ⅜ inch is the usual dimension.

The stresses permitted in rivets are 10,000 lbs. per square inch in single shear and 20,000 lbs. per square inch bearing stress. These figures are for shop-driven rivets: for rivets driven by power in the field a reduction of 10 per cent., and for hand-driven rivets a reduction of 25 per cent. is prescribed. The gusset-plates in the main truss were principally ⅝ inch thick, and the minimum thickness of material allowed throughout the bridge was ⅜ inch.

The towers are of the usual viaduct construction, and consist of two "bents" braced together longitudinally. Each bent consists of two inclined posts with sway-bracing between them. As indicated in Fig. 4, the sway-bracing is made up of panels of crossed diagonals and horizontal struts. This is the type most usually adopted, although occasionally the struts are omitted except at the extreme top and bottom, and the diagonals are made rigid enough to resist compression effectively. In the usual design, typified by the Boucanne River Viaduct, the diagonals, although made of stiff shapes, are proportioned for tension with a limit of slenderness determined by making the maximum permissible ratio of unsupported length to radius of gyration equal to 200. The horizontal struts are then calculated as compression members, and their stiffness is governed in turn by a clause limiting l/r to 120. Under these conditions the choice of sections is governed more generally by the stiffness than by the calculated stress.

The longitudinal bracing between the bents is calculated to take any stress that might occur from applying or releasing suddenly the brakes on the train. Here again, however, with the National Transcontinental Railway, the same stiffness clauses operate: in the smaller towers they determine the dimensions of the diagonals and struts, whilst in the larger towers carrying the ends of long spans the calculated stresses often call for thicker metal. A typical diagram is given (Fig. 4) showing the stresses computed and the material supplied for the particular tower to be considered in this paper.

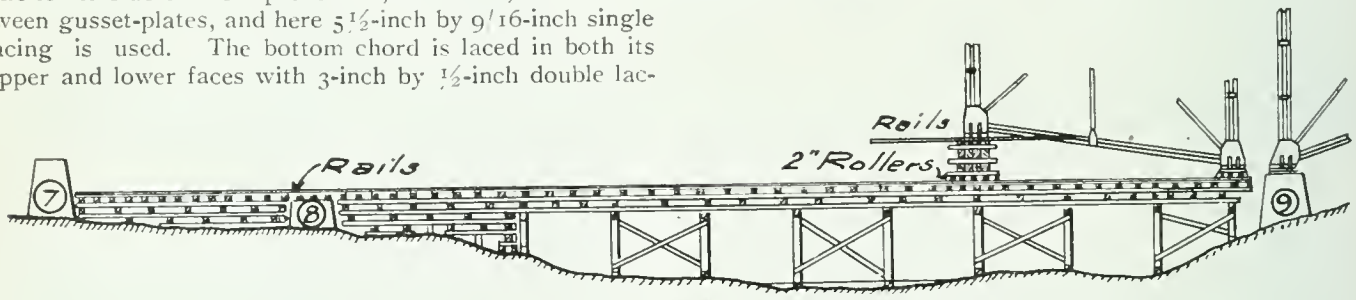

Fig. 5.—Staging Track for Moving Towers Into Place.

As shown in Fig. 4, the posts are made up of three I-beams riveted together to form an H section, reinforced by side plates where necessary. This form of section for posts entails the minimum of shop-work, and secures reasonable connections for all bracing. When the two I's

are deep, they may be connected at suitable intervals between bracing-points by batten-plates, or may be latticed continuously. In the case of the Boucanne Viaduct the batten-plate system was employed, and 9-inch by ⅜-inch plates 1 foot 3 inches long were provided on each face at intervals of about 5 feet. In the tower 7-8 under consideration the lowest story was built up of two 20-inch I-beams, each weighing 90 lbs. per lineal foot, with a diaphragm I-beam 15 inches deep and weighing 60 lbs. per

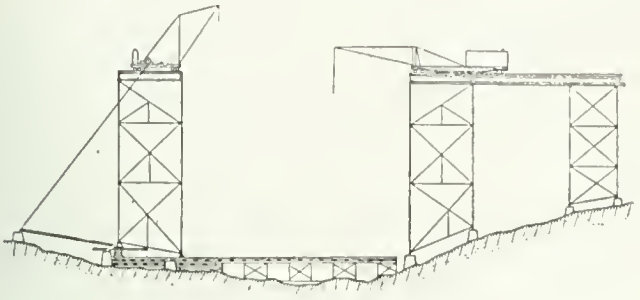

Fig. 6.—Method of Moving Tower.

foot. In addition, there were two 16-inch by ½-inch side plates, one on the outside of the web of each 20-inch beam, giving a total gross section of 86.6 square inches. The beams are of heavy American standard sections, and were rolled by the Carnegie Steel Co. The loads on this post, No. 8, are computed to be as follows:

Dead load	149,500
Live load	276,900
Impact	179,800
	606,200
Wind load	264,000
Brake load	231,200
Total	1,101,400

These loads are the maximum that can co-exist according to the specification and not necessarily the maximum amount of each and every class of load. Now the unit compressive stress allowed by the specification is that given by the formula $16{,}000 \div \left(1 + \frac{l^2}{9{,}000\, r^2}\right)$. This applies, however, to the combination of dead, live and impact loads which, as above detailed, amount to 606,200 lbs. In the story under inspection $l/r = 72$ and consequently $f = 10{,}150$ lbs. per square inch. But in consideration of the remoteness of the possibility of all the wind load and all the brake load occuring together and at the same time as such a large impact load, which the braking load either removes or replaces, the allowed unit for the full combination of live, dead, impact, wind and brake loads is increased above that already determined by 25 per cent. There are thus two cases to be considered in every post—first, the ordinary combination at the ordinary unit; and, second, the extraordinary combination at the increased unit. In the present case, as with most cases of high towers and long spans, the second case governs and so the unit of 12,688 is used, necessitating 87 sq. ins. of section.

The feet of the posts are shod with a steel shoe plate 2 ins. thick which rests upon a steel bed plate 1½ ins. thick, the latter being anchored to the pedestals. The anchor bolts for bent 8 were 1¾ ins. diameter and 6 ft. long, two to each post, whilst to bent 7 were given 2½-in. diameter bolts 13 ft. 3 ins. long, two to each post. A few inches of each bolt project above masonry to receive nuts and washers above shoe plates, and the rest is built into the pedestals. A space is left around the bolt to allow of slight adjustment and then after the towers are completed this space is filled with cement grout.

One post of each tower was rigidly fixed to its bed plate, but the other three were allowed freedom to move under expansion or contraction from temperature or loading. Each of the posts adjacent to the fixed one is permitted to move in the direction of the line adjoining to the fixed one; that is, the one transversely to the viaduct axis, and the other longitudinally with the viaduct axis, while the diagonally opposite post can move in any direction. In other words, one shoe being fixed two had one degree of freedom and the other two degrees. Tongue and grooves in the bed and shoe plates, respectively, were used to accomplish this, and in the particular tower under notice the S. E. post was the fixed one. The tongues were 2½ x 5/16-in. flats and the grooves were planed out 7/16-in. depth.

Construction Details.—The viaduct was erected from the east end, and as the line itself was the only approach, the steel had to be forwarded from Montreal to the station on one of the existing railways nearest to the constructed track. This meant the carrying of all steel by the derrick cars from the east end storage to the actual site and over the erected portions. The process, therefore, was to erect bent 14 and place the 60-ft. girders from the east embankment. The derrick then moving into the 60-ft. girders erected bent 13 and the longitudinal bracing and the 30-ft. girders. This method, obvious and ordinary, was followed to bent 9. For the higher bents a horizontal temporary strut is employed to steady and support the first bent of a tower, being erected between it and the last completed tower. These temporary struts serve to stiffen the bent while the 60-ft. girders are placed and the derrick advanced to erect the rest of the tower. They were wooden in the case of the Boucanne River Viaduct, but are of steel for larger and higher towers.

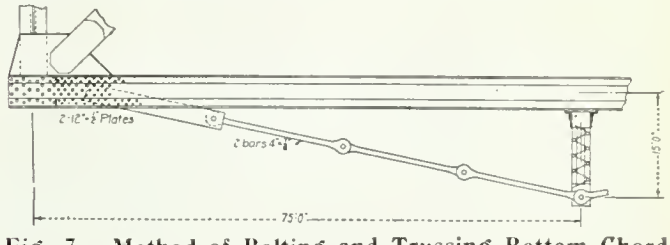

Fig. 7.—Method of Bolting and Trussing Bottom Chord for a One-Piece Erection.

When the tower 9-10 was completed, the next necessary undertaking was bent 8, which in its final position was to be 150 ft. west of bent 9. As this could not be erected from the west end, there being no line, it was essential to scheme out some method of building the complete tower 7-8 before the truss span which it was destined to carry. Although the river was but a foot or two in depth, falsework for the truss was considered too expensive and troublesome, and the plan now to be presented was selected as the most feasible and desirable means of erecting both the trusses and the tower. The outline of the scheme was the building of tower 7-8 on low staging close to 9-10 within reach of the derrick booms and approximately at its final level, and then rolling or sliding it westward into place. The company had before had experience with the moving of towers by this means and

were satisfied from past successes that this was a possible and practicable scheme. Temporary wooden staging was built across the river upon which were laid the skidding or rolling track rails. These were laid at such a height that between their bases and the top of the pedestals of 8 there was just room for an ordinary railroad tie and an inch or two of blocking, Fig. 5. On top of these rails were then built the posts of bent 8. The base of bent 7 being 6 ft. higher than bent 8, this amount of timber blocking was built upon the rails 40 ft. west of bent 8 and upon this small timber tower bent 7 was erected. When the bracing and 40-ft. girders of this tower had been completed a stiff-leg derrick was built on top of the tower by the erection derrick on tower 9-10, Fig. 6.

Between the shoe plates of bent 7 and the blocking upon which they rested was placed another set of rails, so that when the tower had been rolled westward until blocking under bent 7, having passed pedestal 8, was about 8 ft. from pedestal 7 they would project over pedestal 7 and when staged or blocked, would form a track upon which

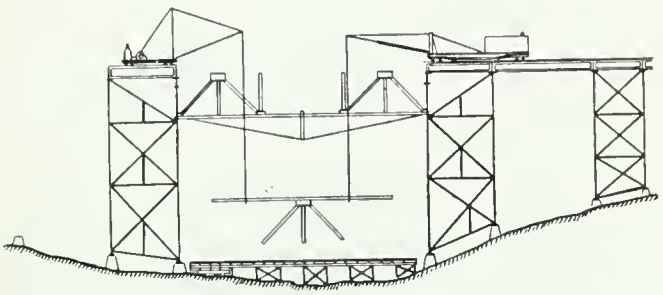

Fig. 8.—Method of Hoisting and Erecting Trusses.

the shoes of bent 7 could slide the last few feet of their travel, the shoes of bent 8, of course, still rolling. Thus for the first 135 ft. or so the two bents of the tower rolled on the lower tiers and afterwards the higher shoes slid on the upper tiers. The rollers were 2 ins. in diameter and about 4 ft. in length. In this manner the tower was rolled to position and then jacked down onto its anchor bolts which were already in place on the pedestals. The rolling was effected by the winding engine of the stiff-legged derrick on top of the tower rolled. Lines from its spools to a hitch west of pedestal 7 passed back to the tackles, which were placed around posts at gussets and around the blocking under 7. The derrick up above thus pulled the tower carrying it into place. The movement was very easily accomplished and without any trouble or hindrance.

The next problem was the erecting of the truss span. The two bottom chords were lowered piece by piece to the staging already referred to, a few feet only from the ground, and there they were bolted up and trussed as shown in Fig. 7, by temporary eye bars and short struts. By this means they were made strong enough to carry themselves and a part of their respective trusses as spans of 145 ft. 6 ins. length. The end vertical posts of the trusses had, of course, been already erected as part of the towers and the bottom chord and splices were arranged to permit of the trussed chord being hoisted vertically and immediately bolted to the short end sections, which were shop riveted to the gusset plates at the foot of the vertical posts incorporated into the towers. By this means the two bottom chords were hoisted into place and connected, the stiff-legged derrick on 7-8 taking hold of about 40-ft. out and the main traveller taking hold of about 50 ft. out. The bottom lateral bracing was then put in place and the chords thus stayed horizontally.

The next process (Fig. 7) was the erecting on the low staging of the web members of the two panels at each end of each truss; that is, the main compression diagonal, the first vertical and the main tension diagonal. These were then hoisted into place and immediately braced by the placing of the first floor-beam and sway-bracing. The second verticals being added, the remaining central portion of each truss was assembled down below with the four panels of top chord and then similarly hoisted up to position and bolted on. The intermediate floor-beams, sway-bracing and top lateral bracing followed and the addition of end sections of top chords and stringer girders completed the span. When sufficient riveting had been done the temporary eye bar trussing was removed and everything was ready for the laying of track and the passage of the erection derrick. The stiff-legged derrick was dismantled and the erection of the remaining towers was proceeded with on the same plan as above described for the eastern shore. The photograph of the placing of the last girder is interesting in that it shows the device whereby a brace frame is hoisted above the second girder of a span, so that immediately both girders are correctly placed they can be braced together.

The main erection derrick had an interesting feature in its telescopic booms. They were built of steel sections in two lengths each, and so arranged that the outer half could enter the inner half and the effective boom thus shortened. Holes and pins were provided in the webs of each position of each boom whereby various lengths could be obtained and retained. The capacity of the booms was 15 tons per boom when shortened down to about 40 ft., and 10 tons each when acting at their full extension of 62 ft.

The greatest weight lifted in this viaduct was about 20 tons, divided between the derrick and the stiff-leg erected on tower 7-8. This weight comprised the centre portion of the 150-ft. span, was 394,185 lbs., and the total in the viaduct 913 tons.

The steelwork was manufactured and erected by the Dominion Bridge Co., Limited, of Montreal, under the supervision of R. F. Uniacke, bridge engineer to the N.T.C.R. Mr. F. P. Shearwood is the designing engineer of the company, and Mr. J. Finley the erection superintendent, while the author as assistant designing engineer was in responsible charge of the designing of the work above described.

The year 1910 has stood the record year for the production of coal in British Columbia, with a total of 3,139,235 tons (2,240 lbs.). The production in 1912 amounted to 3,025,709 tons, which is the second highest annual production, labor troubles being responsible for the lesser output than that of 1910.

Engineers and contractors from many sections of the country are to gather at Cleveland, Ohio, September 17 and 18, on the occasion of the tenth annual meeting of the National Paving Brick Manufacturers' Association. In former years the association has held its annual meetings during winter months, but at the last yearly assemblage of the paving brick manufacturers, it was decided to hold future conventions during an "open season." This will afford, besides the usual programme of written papers, discussion and criticism of brick street and brick road construction methods while work on the highways is in actual progress. The large amount of construction work in the district, will afford splendid opportunity for investigation in a most practical way.

COAST TO COAST.

Saskatoon, Sask.—The city council has decided to prospect systematically for natural gas throughout this district, and Mr. W. R. Martin, a leading expert from Medicine Hat, has been engaged for that purpose. Mr. Martin will endeavor to trace the gas strata to where it comes closest to this city. Borings will then be made, and, in the event of the discovery of gas, the practicability of piping it to the city will thereafter be considered. It will be remembered that Calgary pipes her gas from Bow Island, a distance of 185 miles.

Saskatoon, Sask.—The construction of the big Dominion Government interior elevator at Saskatoon will be commenced upon within the next few weeks. At the outset, its capacity will be three and one-half million bushels. The plans, however, permit of its extension to twenty million bushel capacity, as occasion may later require. When here recently, Grain Commissioner Jones stated that the Saskatoon elevator would be able to handle 150 cars of grain per diem, and when completed would be one of the largest elevators on the continent, exceeding the elevator at Fort William, and having a larger capacity than either of the two Canadian Northern Railway elevators at Port Arthur. The structure will be of reinforced concrete, and absolutely fireproof. Contracts will be let before September 1st. The site will be served by the three railways. The location of the elevator at this city, of course, involves the establishment of a sample market also, and, in due course, a grain exchange.

Guelph, Ont.—At a recent meeting of the Sewerage and Public Works Commission, plans and specifications were presented for important improvements contemplated to the Neeve Street bridge. This shows that the board fully realizes that in order to prevent floods, such as occurred in the spring of 1912 and 1913 action must be taken this season while the water in the river is low. The plans call for another 24-foot arch on the north side of the bridge, and for other extensive improvements to the river and banks. It is proposed to clean out the bed of the river, both below and above the Neeve Street bridge for some distance, and also to erect a retaining wall for about 75 yards above the bridge, and also on the opposite side of the river below the bridge. Every effort will be made to allow plenty of room for the flood water to flow down the river without its flooding its banks. It is understood that this action on the part of the city will not in any way prejudice the case now before the courts, and the Board feel the necessity of taking immediate action to prevent a flood in 1914.

Regina, Sask.—Mr. A. S. Porter, who has been working diligently with a view to materially reducing the cost of production of power in this city, has offered to sell power to the city at $18 per horse-power per 10-hour day. The present rate for power is 1.1 cents per k.w., and Mr. Porter's offer is to sell to the city at .7 cents. It is not thought likely that the city will accept, however, as when the new power-house is completed, it is expected that the cost of production will be materially reduced.

Toronto, Ont.—Hon. Dr. Reaume is likely to introduce legislation at an early session changing the rural main road allowance from 66 feet, as at present, to accord with the newer standard. It is pointed out by the Government's engineers that the standard rural main roads are but 24 feet, and with allowance for paths of four feet on each side and ditches, 40 feet would be ample. The present road allowance leaves a vast acreage of land which might be planted, and forms many miles of growth by vicious weeds. The new standard road likely to be authorized on recommendation of the Highways Commission will be of slight grade 24 feet wide, and with very sharp curves obliterated. The data obtained by the department show that the use of motor cars in Europe has multiplied the traffic in the main highways ten times, with the consequent cost of maintenance in proportion.

Toronto, Ont.—The Harbor Commissioners are congratulating themselves on an advantage obtained by the building of the new western channel, which did not enter into their considerations at the time the new channel was planned. The good result obtained is the practical clearance from the bay of debris. Some time ago the suggestion was made by a prominent engineer that the bay water could be kept clear by the construction of a channel at a point about half way between Centre Island and Hanlan's Point, but owing to the big expense involved nothing was done in the matter. The result now obtained has been caused by a strong current which flows from the eastern channel west and out through the western channel and keeps the bay clear. A current strong enough for this purpose was not to be had when the old western channel was used, which was too narrow, and was only about 10 feet deep in places. The new wide channel is more than 18 feet in depth, and is apparently situated just right to catch the current.

Vancouver, B.C.—The fourth annual convention of the Pacific Highway Association met in Vancouver a week ago. Delegates from Seattle, Portland, San Francisco, Los Angeles and a number of other cities are in attendance. The association aims to secure the construction of a first-class road along the Pacific slope from as far north as possible. Except for two short breaks in British Columbia, the highway now stretches continuously from Hazelton, B.C., to Yuma, Ariz. During the winter large sections of the road are impassable, and the association is working to secure the co-operation of the different communities toward an early improvement of the conditions.

Ottawa, Ont.—It is understood that the Canadian Northern Railway is seeking from the Government running rights over the Intercolonial Railway, to take effect from the time when their Montreal to Port Arthur line is finished. The privilege will, of course, not be required until the construction of the line is much further advanced than it is at present. When it is completed next year, the Canadian Northern will have a line as far as Quebec, but will lack connection with the eastern seaboard. No definite plans have ever been formulated by the company to build a new line to St. John or Halifax, and apparently it has been intended to fill that gap by the acquisition of running rights over the Intercolonial. For that reason the application made to the late Government is again being pressed. The intention of the Government towards the application has not been officially stated, though it is known in connection with the question of Government assistance to the line that the matter has been under consideration from time to time. When the former ministry granted liberal bond guarantees to the Canadian Northern it was understood that if at any time the Intercolonial Railway desired running rights west over the Canadian Northern such would be granted. The same privilege is still available, but it is not known whether the Government will utilize it.

Stratford, Ont.—The city's sewage disposal plant, which has been in operation for only a year, is reported to be giving unsatisfactory service. F. A. Dallyn, C.E., of the Provincial Board of Health, recommends the following improvements to increase the efficiency of the system: New sedimentation beds and improved sprinkling equipment, including an auxiliary gas engine; a chlorination device, and a humus bed between the sprays and the creek into which the purified effluent empties.

Regina, Sask.—Mr. Moreley J. Donaldson, vice-president of the Grand Trunk Pacific Railway, while in the city recently stated that a contract would be let within the near future for the construction of the balance of the Regina-Moose Jaw line of his company. With regard to the boundary line, Mr. Donaldson stated that the laying of steel to the boundary would be completed within the course of a few days, and that the line would be ballasted to the boundary by September 15th sufficiently to permit operation. He also stated that the Great Northern Railway line would be completed to the boun dary to connect with the Grand Trunk line as soon as the Grand Trunk Pacific line is completed.

PERSONAL.

GUSTAVE KAHN, general manager of the Trust Concrete Steel Company, of Canada, Limited, Walkerville, Ont., is at present in the West on a business trip.

HENRY F. CLAYTON, general manager of Boving & Company, of Canada, Limited, is spending the month in Western Canada on a tour in the interests of business.

L. S. BRUNER, manager of publicity for the Canada Cement Company, Montreal, is returning from a visit to the company's mills in British Columbia and the Western States.

R. F. UNIACKE, chief engineer of the Transcontinental Railway, has just returned to Ottawa from an inspection as far west as Winnipeg of the bridges and general condition of his road.

W. C. HARVEY is acting city engineer of Lethbridge, Alta., since the resignation of A. D. C. Blanchard. Mr. Blanchard is now associated with C. H. Rust in the city engineer's department of Victoria, B.C.

ARTHUR H. BLANCHARD, M. Can. Soc. C.E., professor in charge of the graduate course in highway engineering at Columbia University, has been retained by the State highway department of Pennsylvania as consulting engineer on the appraisal of certain toll roads.

CHARLES H. EDMONDS, for nine years works chemist and carbonizing engineer for the Birmingham Gas Department, and who subsequently erected and managed a large chemical plant at Middlesborough, England, for Messrs. Reckett & Sons, is now in this country.

J. G. McMILLAN, B.A.Sc., has returned from James Bay, where he has spent five months for the Provincial Government towards the establishment of a suitable harbor location for the proposed terminus of the T. and N.O. Railway. The work of sounding the Bay has been completed.

WILLIS CHIPMAN, of the firm of Chipman & Power, Toronto and Winnipeg, has been engaged by the city of Edmonton in the capacity of consulting engineer for a period of two years at an annual salary of $3,600, Mr. Chipman to visit the city four times in the year, the visits to aggregate thirty days spent in the city.

L. S. ODELL, B.A.Sc., a member of the firm of Linn, Collis & Company, Nipigon, Ont., was in the city last week completing arrangements and securing equipment for the commencement of their contract with the Canadian Northern Railway. This contract covers the concrete work in the construction of fourteen bridges on the eastern division of the Sudbury-Port Arthur line.

D. P. WAGNER and FRED. G. McALISTER have been appointed secretaries of the new Provincial Highway Commission, the former in the capacity of general secretary, and the latter as secretary in charge of statistical work. Both are graduates of the University of Toronto, and Mr. Wagner is a graduate of Oxford as well. Mr. McAlister has acted as secretary of the Good Roads Association for the past year.

JAMES NEWTON GUNN, general manager of the Studebaker Corporation, of South Bend, Ind., has resigned in order to meet the demands made upon his time and services by other clients. Mr. Gunn will remain upon the board of directors of the Studebaker Corporation, but will devote practically his entire time to the firm of Gunn, Richards & Company, engineers and accountants, of New York and Montreal With the assistance of the large staff of engineers and accountants employed by the latter firm, Mr. Gunn and his partner, Mr. Richards, are managers of, or engineers for, a large number of industrial and engineering concerns, several of which are in Canada. Gunn, Richards & Company have a Canadian office at Montreal under the management of H. Victor Brayley.

JOINT MEETING OF PEAT SOCIETIES.

The seventh annual meeting of the American Peat Society will be held jointly with the Canadian Peat Society at the Canadian Society of Civil Engineers' building in Montreal, August 18th, 19th and 20th. Papers to be presented and discussions will embody the results of progress in the production of peat fuel, peat gas and peat moss litter. Emphasis will be given the subject of peat and bog utilization in agriculture, both on this continent and in Europe.

COMING MEETINGS.

ONTARIO MUNICIPAL ASSOCIATION.—Annual Meeting to be held in Toronto, August 28th and 29th. Secretary-treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ont.

THE NEW ENGLAND WATERWORKS ASSOCIATION.—Annual Convention to be held in Philadelphia, Pa., September 10th, 11th and 12th, 1913. Secretary, William Kent, Narragansett Pier, R.I.

THE ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Sixth General Annual Assembly will be held at Calgary, Alberta, September 15th and 16th. President, J. H. G. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Third Annual Meeting in Regina, September 18th, 19th and 20th. General Secretary, Major Lorne Drum, Ottawa; Local Secretary, R. H. Murray, C.E., Regina.

AMERICAN ROAD CONGRESS.—Annual Session will be held in Detroit, Michigan, from September 29th to October 4th. Secretary, J. E. Pennybacker, Colorado Building, Washington, D. C.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—Twentieth Annual Meeting to be held in Wilmington, Del., October 7th to 10th. Secretary, A. Prescott Folwell, 15 Union Square, New York.

UNITED STATES GOOD ROADS ASSOCIATION.—Convention will be held at St. Louis, Mo., November 10th to 15th. Secretary, J. A. Rountree, L021 Brown-Marx Building, Birmingham, Ala.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

AMERICAN CONCRETE INSTITUTE.—First Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

19948—July 30—Refusing the application of R. H. Souch, Tp. of Darlington, Ont., to construct a subway on his Lots 3 and 4, Con. 2, Tp. of Darlington.

19949—August 1—Amending Order No. 19741, dated July 3, 1913, which authorized the C.L.O. and W. Ry. to cross the G.T.R. at mileage 89.9, Tp. of Murray, by adding after the word spur, the words "temporarily for a period of eighteen months from the date of this Order."

19950—August 2—Amending Order No. 19815, dated July 17, 1913, which authorized the City of Regina to construct a street railway across the Arcola Branch of the C.P.R. and the commercial spur of the company, by striking out the words C.N.R. and substituting C.P.R.

19951—July 29—Authorizing C.P.R. to construct a road diversion in Lots 2566 and 9005, Kootenay Dist., at mileage 40.24 to mileage 41.23 from Golden.

19952—July 30—Authorizing the C.N.O. to open for carriage of traffic, the extension of its main line to connect with the Algoma Eastern Ry., mileage 0.0 to mileage 2.39.

19953—July 30—Authorizing C.L.O. and W. Ry. to cross Bogart avenue and Wilkie street, Belleville, Tp. of Sydney, at mileage 78.46 and mileage 78.61 from Glen Tay.

19954—July 29—Authorizing G.T.R. to construct spur to premises of Dowsley Spring and Axle Co., Limited, Chatham, Ont.

19955—July 29—Approving revised location G.T.P. branch lines, Tofield-Calgary branch, southeast quarter of Sec. 11, Tp. 31, Range 24, West of Fourth Meridian, Province of Alberta.

19956—August 2—Approving plan C.N.O. Ry. structure, crossing Montreal Park and Island Ry. Co. at Sault au Recollet, Que.

19957—August 2—Amending Order 18373, dated Sept. 17, 1913, which authorized Toronto Suburban Ry. Co. to cross tracks of G.T.R. at Acton but provided that in addition to tracks authorized to be crossed, authority be given to cross G.T.R. tracks at some further point.

19958—Aug. 8—Authorizing the C.P.R. to construct its Forsyth St. Branch across certain highways in Maisonneuve, P.Q.

19959—Aug. 1—Authorizing the C.P.R., subject to the terms of the consent with the exception of clause 6, to alter the location of the present siding across De Gaspe Ave., and to construct, maintain, and operate an extension to the said siding in Lot Cad. 10-287, incorporated village of St. Louis (Civic) Laurier Ward, Montreal, Co. Hochelaga, Que., for the Sicily Asphaltum Paving Co., Ltd., Montreal.

19960—Aug. 6—Authorizing the C.P.R., subject to the terms of the consent with the exception of clause 5, to construct, maintain, and operate the said branch line of railway or spur, for the Imperial Wire & Cable Co., Montreal, from a point on the C.P.R., thence across St. Patrick St. and across Cad. Lots Nos. 992, 993, 994 and 995 to and into the premises of the said Imperial Wire & Cable Co., situate in said lots.

19161—Aug. 1—Approving change or alteration in the C.P.R. as constructed, at or near the junction of its railway with the C. L. O. & W. Ry., at Glen Tay, Ont.; also approving location of C.P.R. station at Glen Tay at mileage 15.57 on its railway, and at mileage 0 on the C. L. O. & W. Ry.

19962—Aug. 1—Authorizing the C. L. O. & W. Ry. to construct, by means of grade crossings, the tracks of its main line of railway across thirteen highways in the city of Belleville, Ont.

19963—Aug. 8—Amending Order No. 19962 by striking out the words "as lessee of and exercising the franchises of the Alberta Railway and Irrigation Co." in the recital to said Order.

19964—Aug. 7—Authorizing the C. L. O. & W. Ry. to construct bridge No. 76.85 over the Moira River at Belleville, Ont.

19965—Aug. 6—Ordering the C.P.R. to provide and construct a suitable cattle-pass, utilizing the ditch on the farm of R. J. Patterson, of Omemee, Ont.

19966—Aug. 1—Authorizing the C.P.R. to construct an additional track across Bloor St., Lansdowne Ave., and Brock Ave., Toronto.

19967—Aug. 5—Approving and authorizing the clearances of C.P.R. siding at the proposed warehouse of the Colonial Wire Manufacturing Co., Ltd., in St. Emard Ward of the city of Montreal, on the Lachine Canal, South Bank Branch of C.P.R.

19968—Aug. 6—Authorizing the C.N.R. to construct its line of railway across certain highways on its Alsask Southeasterly Line.

19969—Aug. 5—Ordering the C.N.R. to erect a standard passenger and freight shelter station and platform at Dufresne, Man., within sixty days from date of this Order.

19970—Aug. 6—Authorizing the C.N.R. to construct, maintain, and operate a spur line of railway for Thomson, MacDougall & Co., near Woodlands, Man., through Secs. 21, 20, 19 and 18, Twp. 14, Rge. 2, W.P.M., and Secs. 13 and 12, Twp. 14, Rge. 3, W.P.M., mileage 0 to mileage 5.21, and to construct said spur line across certain highways.

19971—Aug. 5—Authorizing the C.N.R. to construct its line of railway across and divert the public road between Sec. 36, Twp. 25, Rge. 22, and Sec. 1, Twp. 26, Rge. 22, W. 3 M., on its Alsask Southeasterly Line.

19972—Aug. 5—Authorizing the L. E. & N. Ry., subject to the terms of the said consent, to construct its line of railway across two highways in the Township of Brantford.

19973—Aug. 1—Postponing the effective date of the proposed increased rate on brick from Milton to Toronto until the 1st day of November, 1913.

19974—Aug. 2—Amending Order No. 5850 authorizing the crossing by wire of the Toronto and Niagara Power Co., over the right of way of the G.T.R. at Davenport Road, Toronto, Ont., and providing that the said crossing be made in accordance with plan No. 6132, dated April 30th, 1913.

19975—July 30—Approving location of Lake Erie and Northern Railway from Station 0, Lorne Bridge, Brantford, to Station 4.50.

19976—Aug. 6—Ordering the G.T.P. to open the crossing between Secs. 8 and 17, Twp. 10, Rge. 13, W. 2 M., Sask.; and to divert highway between Secs. 8 and 9, to a connection with the road between Secs. 8 and 17.

19977—Aug. 7—Authorizing the C.P.R. to use and operate certain bridges on its line of railway.

19978—Aug. 7—Relieving, for the present, the G.T.R. from providing further protection at the Wilson Street crossing, Woodstock, Ont.

19979—Aug. 5—Extending the time within which the G.T.R. were ordered to construct station at St. Gregoire, Que., until Sept. 30th, 1913.

19980—Aug. 7—Ordering the C.N.R. to enlarge present station at Morinville, Alta., to provide a waiting room at least 30 ft. by 30 ft., with seats for accommodation of the public; lengthen platform to accommodate a four passenger train; and erect a freight shed independent of the passenger station.

19981—Aug. 7—Relieving, for the present, the Windsor, Essex and Lake Shore Electric Ry. from providing further protection at the crossing of the highway known as Pelton Crossing, 7th Con., Twp. of Sandwich South, Ont.

19982—July 30—Approving location of the Lake Erie and Northern Railway Company's line from Station 1107-40.7, in the Twp. of Townsend, to Station 1282-32.3, Twp. Woodhouse, passing through Simcoe, Ont.

19983—Aug. 7—Authorizing the G.T.R. to construct, maintain and operate a branch line of railway, or siding, commencing at a point on its railway on St. Patrick St., St. Anne's Ward, Montreal, thence extending upon, along, and across St. Patrick St., crossing the C.P.R.'s spur on said street, to and into the premises of the Imperial Wire and Cable Co. on the south side of said street.

General Order No. 108, Aug. 11th—Ordering the C.P.R. to withdraw its special rule "F" applying to western lines and hereafter observe the uniform rules of the Board regarding yard limits.

19985—Aug. 11—Relieving, for the present, the C.P.R. from providing further protection at the crossing of the road allowance between Secs. 24 and 25, Twp. 31, Rge. 1, west of the 5th Mer., Didsbury, Alta.

19986—Aug. 9—Approving location of C.P.R. proposed shelter on the N.W. ¼ of Lot 10, Con. 8, Twp. of Ops, Co. Victoria, Ont., at Hillhead.

19987—Aug. 11—Refusing application of the Board of Trade of Limerick, Sask., for an Order directing the C.P.R. to provide and construct a highway crossing over its railway on Galway or Brian Sts., townsite of Limerick.

19988—Aug. 5—Authorizing the G.T.R. to construct and maintain a culvert under its tracks, Twp. of Tecumseth, at the Seventh Con. line.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

RAILWAYS—STEAM AND ELECTRIC.

Moose Jaw, Sask.—Double tracking on the Canadian Pacific Railway will be completed to Swift Current in a short time. The double track is now in operation, west as far as Chaplin, 54 miles, and east to Regina, 42 miles.

Ottawa, Ont.—Tenders will be received up till September 8th, 1913, for double tracking the line between St. Romuald and Chaudiere Curve, P.Q. Plans and specifications may be obtained at the Station Master's office, Levis, P.Q.; office of the Assistant Deputy Minister and Secretary, Department of Railways and Canals, Ottawa, Ontario; and also at the Chief Engineer's office, Moncton, N.B. L. K. Jones, Assistant Deputy Minister and secretary, Ottawa.

Toronto, Ont.—Mayor Hocken has just signed the final plans providing for the construction by the railway companies of a viaduct along the waterfront, thus confirming the statements of the transportation companies that they will be in a position to invite tenders this autumn.

BRIDGES, ROADS AND PAVEMENTS.

Brantford, Ont.—Tenders will be received up till August 30th, 1913, for the construction of 7,810 linear feet of four-foot cement sidewalk. Plans and specifications may be obtained from Alan Mair Jackson, Town Engineer.

Cayuga, Ont.—Tenders will be received up till September 16th, 1913, for the construction of 26½ miles of stone macadam road. Plans and specifications may be obtained from County Engineers, Messrs. Jackson & Kyd, Dunnville. T. A. Snider, County Clerk.

Cranbrook, B.C.—Work has been commenced on the construction of the bridge across the Kootenay River from Mayook to Bull River.

Dover, Ont.—Tenders will be received up till August 25th, 1913, for the erection of two steel and concrete bridges, 73-ft. span over Little Bear Creek. Plans and specifications may be obtained from the offices of the Clerk or Engineer, W. G. McGeorge, Queen Street, Dover.

Galt, Ont.—An important move in the good roads direction was made by the council in contributing a thousand dollars towards a sixteen foot macadam road from Galt to Preston. North Dumfries Township gives two thousand. Waterloo also aids and the Auto League subscribes $1,000. The Government grant makes up the balance.

▲—**London, Ont.**—Tenders will be received up till September 11, 1913, for the supply and erection of three 130 feet spans rivetted truss steel highway bridge over the River Thames, the substructure for which is already under construction. Plans and specifications may be obtained from Wm. N. Ashplant, city engineer, London.

Moncton, N.B.—Tenders will be received up till August 22nd, 1913, for the extensions to sewers. Plans and specifications may be obtained from J. Edington, City Engineer.

Montreal, Que.—The Board of Control is considering contracts for a large amount of asphaltic macadam pavements and awards will likely be made within a few days. Tenders were opened last week, bids being received from a number of firms, including the Sicily Asphaltum Paving Co., the Warner-Quinlan Co., the Bitulithic Company, etc.

New Westminster, B.C.—The Great Northern Railway has decided to replace the old building near the Fraser River bridge, which has been for years designated as a station, with a temporary building to cost in the neighborhood of $5,000.

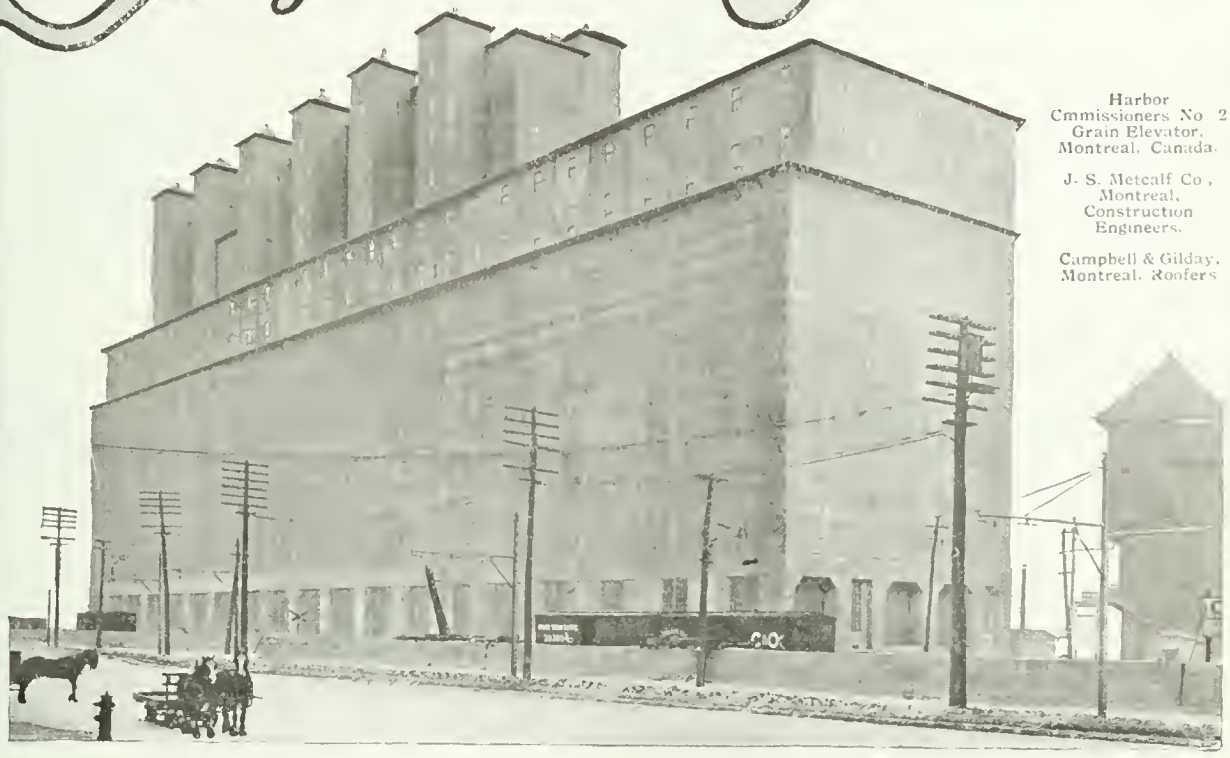
Ottawa, Ont.—An attempt is being made to get the Government to sanction the carrying out of the Channel Tunnel scheme. It is the desire of the English people to build a bridge across the English Channel. This bridge would be seventy miles long and the cost is estimated at $110,000,000.

+—**Regina, Sask.**—The following are the contracts for bridges that have been recently awarded by the Government:—Pinto Creek district, three bridges; North Battleford district, three bridges; Yorkton and Canora districts, four bridges to construct and five to repair; Prince Albert district, two bridges; Pelly district, four bridges: Saltcoats district, four bridges; Maple Creek district, two approaches to be graded; Pheasant Hills district, five bridges and repairs to a dam and bridge.

Regina, Sask.—The city council has contracted with the WESTRUMITE PAVING COMPANY for the construction of the paving on Rose Street, from the Canadian Pacific Railway station to South Railway Street. The company's tender was $1,701.60.

Regina, Sask.—Five steel bridges have been authorized by the provincial government and work will be proceeded with immediately. The bridges are as follows:—100 foot span over the Qu'Appelle River, near Disley; 40 foot span

Barrett Specification Roofs



Harbor Commissioners No 2 Grain Elevator, Montreal, Canada.

J. S. Metcalf Co., Montreal, Construction Engineers.

Campbell & Gilday, Montreal, Roofers

On the World's Largest Concrete Grain Elevator

As we have frequently pointed out, most of the large commercial buildings of the day are covered with a Barrett Specification type of roof.

For example, here is the great new grain elevator at Montreal. It is said to be the largest in the world, with a capacity of 2,600,000 bushels. It carries a Barrett Specification Roof 55,000 square feet in area.

The engineers chose this type of roof because it is the lowest-priced and most reliable roofing known.

Barrett Specification Roofs require no repairs or attention of any kind, they invariably last twenty years or more, and are fire-retardant.

Architects, engineers and owners of permanent buildings of all kinds should have a copy of the Barrett Specification on file.

A request will bring it by return mail.

Special Note

We advise incorporating in plans the full wording of The Barrett Specification, in order to avoid any misunderstanding.

If any abbreviated form is desired, however, the following is suggested.

ROOFING—Shall be a Barrett Specification Roof laid as directed in printed Specification revised August 15th, 1911, using the materials specified and subject to the inspection requirement.

THE PATERSON MANUFACTURING COMPANY, LIMITED

Montreal Toronto Winnipeg Vancouver St. John, N.B. Halifax, N.S. Sydney, N.S.

near Kandahar; 150 foot span over the Assiniboine River, near Preeceville; 126 foot span over the Whitesand River, near Canora; 150 foot span over the Assiniboine River, near Kamsack. The abutments of these bridges will be completed this fall.

Saskatchewan, Sask.—The Canadian Pacific high-level bridge across the Saskatchewan River, from Strathcona to Edmonton, is now completed, the cost of which is slightly over $1,000,000.

St. Catharines, Ont.—The city of St. Catharines is preparing to construct rocmac and concrete pavements to the estimated cost of over $26,000. J. A. Pay, City Clerk.

St. Catharines, Ont.—The city of St. Catharines is making provision for the construction of 4 and 5-foot concrete sidewalks, the estimated cost of which amounts to over $6,000. J. A. Pay, City Clerk.

Walkerton, Ont.—Mr. A. G. HAMPSON has been awarded the contract of putting on a new floor and repairing the East End bridge. The contract price is $1,700.

LIGHT, HEAT AND POWER.

Calgary, Alta.—Tenders will be received up till September 3, 1913, for the manufacture of luminous arc lamps standards. Plans and specifications may be obtained from the office of the City Electrician, Calgary, Alberta. J. M. Miller, City Clerk.

Cochrane, Ont.—Sutcliffe and Neelands, engineers, of New Liskeard, are making preparations to build a new concrete power house and install the new steel flume. The power house will be fitted with first-class machinery for the development of electric power.

Montreal, Que.—Tenders will be received up till August 21st, 1913, for the electric lighting installation at Bonsecours Market. Plans and specifications may be obtained from the Superintendent, Lighting Department, City Hall. L. N. Senecal, Secretary.

New Dundee, Ont.—New Dundee is carrying on an active campaign with a view to securing Niagara power. The proposition is to connect with the Baden line at Petersburg and to carry power south to New Dundee six miles. Mr. Purcell, one of the engineers of the Hydro Commission, was in New Dundee and explained matters. Now it is only a question as to the amount of power to be subscribed. The villages of Phillipsburg and Wellesley are also seeking information with a view to carrying the power north.

Regina, Sask.— BRUCE, PEEBLES & COMPANY, LIMITED, of Edinburgh, have been awarded by the City Commissioners the contract for supplying a 1,200 K.W. motor generator.

Wentworth, Ont.—Tenders will be received up till August 25th, 1913, for alterations to the steam heating system in the Court House. For particulars apply to George Anderson, Engineer.

GARBAGE, SEWAGE AND WATER.

Calgary, Alta.—City Waterworks Engineer Fawkes is now investigating for Calgary the advantages of a modern mechanical filtration plant and pumping stations with a capacity of forty million gallons per day. Calgary has considered filtration before, but owing to the possibilities of being able to obtain a pure mountain supply the filtration project was abandoned. Mr. Fawkes is strongly in favor of filtration, and, supported by the administration and general public, will expedite matters along these lines at an early date.

Moncton, N.B.—Tenders will be received up till August 22, 1913, for extensions to sewers. Plans and specifications may be obtained from J. Edington, City Engineer.

Ottawa, Ont.—The city council awarded LOAMIS, McBEAN & WILLIAMS, of Montreal, the contract for lifting the old intake pipe, repairing and relaying it. The estimated cost is $17,000.

Peterboro, Ont.—An 18-inch feed main will be added to the waterworks system, on account of the rapid increase in population. Later in the year further extensions will be made.

Port Arthur, Ont.—Tenders will be received up till August 25th, 1913, for the installation of water main from Second Avenue to Midway. Plans and specifications may be obtained from City Engineer, Port Arthur, Ont. J. J. Hackney, Commissioner Utilities.

Regina, Sask.—The operation of the new sewage disposal works was commenced last week. All the work has now been completed, and it is hoped to be able to give the system a good try-out before winter sets in.

Saskatchewan, Sask.—The work on the Saskatchewan River is good for navigation as far as Le Pas, Manitoba, and orders have been received to complete it to Grand Rapids. A channel ten to twenty feet deep was found the entire way from Cumberland House and extra work was unnecessary. Eventually the waterway will be continued through to Winnipeg, Manitoba.

Stratford, Ont.—The Council instructed City Engineer Manson to proceed at once with plans for addition to the sewage disposal works, as ordered by Provincial Engineer Dallyn, including sedimentation tanks, chlorination device, humus beds and auxiliary pumping equipment.

St. Catharines, Ont.—The city of St. Catharines intends to construct tile sewers on a number of its streets, the estimated cost of the work being $3,500. J. A. Pay, City Clerk.

INDUSTRIAL WORKS.

+—**Burrard Inlet, B.C.**—Grant, Smith and McDonnell have been awarded the contract for the under-structure work on the warehouses to be built on the new Great Northern Railway. Work will commence shortly.

Calgary, Alta.—A report from Ottawa states that the Government will shortly undertake the construction of a $300,000 office building for the accommodation of local federal officials.

Calgary, Alta.—The Federal Government intends to build one of the finest post-offices in the Dominion.

Calgary, Alta.—A new government armory building will be commenced as soon as the council can decide upon a suitable site.

Dundas, Ont.—The Tocan Manufacturing Company, capitalized at a quarter of a million dollars, has purchased a factory on Cross Street, and will shortly start to manufacture different kinds of sheet metal goods.

Edmonton, Alta.—Nicholson & Bain, of this city, will spend $70,000 in the construction of a six-story warehouse. It will be of brick and stone, with a concrete foundation.

Edson, Alta.—The town council are considering the arrangements for the construction of a new fire hall.

Fort William, Ont.—The Department of Militia and Defence is calling for tenders for the construction of an armory building. The proposed armory will be one of the largest and most up-to-date in the Dominion. Plans of the building may be seen at the office of the City Clerk of Fort William.

Fort William, Ont.—Tenders will be received up till September 4th, 1913, for the construction of a new drill hall. Plans and specifications can be obtained at the offices of the District Officer Commanding Military District No. 10, Winnipeg, Man.; the City Clerk, Fort William, Ont., and the Director-General of Engineering Services, Headquarters, Ottawa. Eugene Fiset, Deputy-Minister, Ottawa.

+—**Fredericton, N.B.**—SMITH, MERRITHEN AND COMPANY have been awarded the contract for the construction of several buildings. The contract price is $39,400.

+—**Greenwood, B.C.**—JOHN BEMIS & SON have been awarded the contract for a public building. The contract cost is $41,000.

Halifax, N.S.—The new warehouse which is to cost in the neighborhood of $100,000 will be begun shortly.

Humboldt, Sask.—A new public school has been recommended for the town of Humboldt. It will cost in the neighbourhood of $65,000.

+—**Indian Head, Sask.**—James McDiarmid and Company, of Winnipeg, has been awarded the contract for a new drill hall. The contract price is $13,700.

MANNESMANN TUBES

Six Hundred Authorities Are Using Mannesmann Tubes

in Great Britain in varying quantities up to 15 miles; in Canada, to 17 miles.

Seven hundred miles of weldless steel spigot and faucet tubes—quite apart from flanged tubes and lapwelded spigot and faucet tubes—are in use in the United Kingdom, as well as large quantities in Canada, Australia, South Africa, South America, India, China, New Zealand and Europe.

We are constantly adding new customers to our list, and, what is of even greater significance, more frequently still receiving repeat orders.

Solid drawn tubes are used in places where it is impossible to use cast-iron pipes or lapwelded tubes, as well as in places where the conditions are more normal.

In the past five years the sale of Mannesmann weldless steel spigot and faucet tubes (home trade alone) increased one thousand per cent., and during the last financial year reached the figure of about 5,000 tons, equal to 15,000 tons of cast-iron, in addition to a large export business.

MANNESMANN TUBE CO. LIMITED

59 Victoria Square, MONTREAL

BOOKLETS ON REQUEST

Listowel, Ont.—Tenders will be received up till September 16th, 1913, for the construction of a new drill hall. Plans and specifications may be obtained at the offices of the Officer Commanding the First Division, London, Ont.; the Town Clerk, Listowel, Ont., and the Director-General of Engineer Services, Headquarters, Ottawa. Eugene Fiset, Deputy Minister.

Medicine Hat, Alta.—The Western Threshing Machine Company, capitalized at $100,000, intend to erect a large plant here. They have been granted the usual concessions, and will manufacture a newly patented thresher. It is expected that it will be in operation in a very short time.

+—Montreal, Que.—John Metcalfe Company, of Montreal, have been awarded the contract for the erection of all buildings on the new lake shore line of the Canadian Pacific Railway, giving a double track between Montreal and Toronto.

+—Montreal, Que.—A. C. Stewart has been awarded the contract for the construction of the Fife Hardware Company's wholesale warehouse. The contract price is $40,000.

Montreal, Que.—The Imperial Wire and Cable Company have just received a permit to build a $1,100,000 works. The building will vary in height from four to eight stories and will be built by Mr. E. G. M. Cape and the Dominion Bridge Company.

Montreal, Que.—It is reported that Lockwood, Greene & Company, engineers and architects for industrial plants, are establishing a branch office in Montreal.

Montreal, Que.—A new grain elevator, especially for export trade, with a capacity of nearly three million bushels, will be built by the Harbor Commissioners. Although the site has not been decided upon, it was announced by an official that the new elevator will be situated in the east end in such a way that boats can be unloaded on one side and loaded on the other.

Moose Jaw, Sask.—Tenders will be received up till September 8th, 1913, for a grain elevator. Plans and specifications may be obtained from the Board of Grain Commissioners for Canada, Fort William, Ont. T. J. Code, Acting Deputy Minister, Ottawa.

North Battleford, Sask.—The following public buildings have been recommended:—A new school costing $145,000, and a new post office costing $50,000; also a government armory to cost $25,000.

+—North Lethbridge, Alta.—Bario Secont, contractor of Blairmore, has been awarded the contract for the erection of a factory for the Marinaro Brothers.

▲—Ottawa, Ont.—The Government has invited architectural sketch designs for the erection of departmental and courts buildings, which are to be in not later than January 2nd, 1914. Conditions for these designs may be had on application to R. C. Desrochers, secretary, Department of Public Works, Ottawa, and also at the office of the High Commissioner for Canada, 17 Victoria Street, London, England. R. C. Desrochers, secretary, Ottawa.

Prince Albert, Sask.—Tenders will be received up till noon, August 25th, 1913, for the construction of a drill hall. Plans and specifications may be obtained from Eugene Fiset, Deputy-Minister, Ottawa.

+—Red Deer, Alta.—NESBITT & MILLER have been awarded the contract for a drill hall. The contract price is $36,000.

+—Red Deer, Alta.—Nesbitt and Millar have been awarded the contract for an armory building. It will cost approximately $36,000.

Sarnia, Ont.—The harbor improvements here are being held up at the present time on account of the town councillors not being favorable to dredging in the bay, which is just above the waterworks intake pipe. It will be remembered that the Government set aside $50,000 last year to start these improvements.

Saskatoon, Sask.—Tenders will be received up till September 8th, 1913, for a grain elevator. Plans and specifications may be obtained from the Board of Grain Commissioners for Canada, Fort William, Ont. T. J. Code, Acting Deputy Minister, Ottawa.

Smith's Falls, Ont.—Contracts for all the new buildings along the new Canadian Pacific Railway line from Agincourt to Smith's Falls have been awarded to JOHN METCALFE. The contract includes seven brick stations, nine wooden stations, nine forty thousand gallon water tanks, a ten-stall engine-house and sand-house, an icehouse, nine freight sheds, seven station residences, twenty-five tool houses and other small structures, making a total of eighty-five buildings.

Steelton, Ont.—Tenders will be received up till September 9th, 1913, for the construction of a public building. Plans and specifications may be obtained from Thomas R. Wilks, 612 Queen Street, Sault Ste. Marie, Ont., and also from the Department of Public Works, Ottawa, Ont. R. C. Desrochers, Secretary.

+—Sudbury, Ont.—DORAN AND DEVLIN, of Ottawa, have been awarded the contract for the construction of a public building. The contract price is $98,200.

Thorold, Ont.—Pilkington Bros., Limited, are erecting a glass factory at Thorold, Ont., and desire to get in touch with some first-class machine shops and foundries in which they could have fabricated the special machinery necessary to glass-making. Machine shops and foundries who might desire to bid on this work are requested to write to A. R. Turnbull, 29 Chestnut Street, St. Catharines, Ont.

Toronto, Ont.—The Department of Militia and Defence combined with the contract branch of the Department of Public Works, has cancelled the tenders for the new barracks at Long Branch, Toronto. It is expected that new tenders will be called for by the end of this month.

+—Trenton, Ont.—JOHN METCALFE COMPANY, of Montreal, have been awarded the contract for the erection of a new station, and also a freight shed nearly a hundred and fifty feet long, enclosed tank with 40,000 gallons capacity, tool house, turntable, twelve-stall locomotive house, machine and boiler house, and coaling plant.

+—Vegreville, Alta.—A. E. Jennings has been awarded the contract for the construction of a drill hall. The contract price is $15,000.

Winnipeg, Man.—Tenders will be received up till September 3rd, 1913, for the construction of a drill hall. Plans and specifications may be obtained from H. E. Matthews, Superintending Architect of the Dominion Public Buildings, Winnipeg. R. C. Desrochers, Secretary.

Yorkton, Sask.—The Provincial Government has announced its intention of erecting a new telephone exchange at this point in the near future.

MISCELLANEOUS.

Annapolis County, N.S.—Tenders will be received up till September 3rd, 1913, for the construction of ice piers. Plans and specifications may be obtained at the Department of Public Works, Ottawa, and at the offices of C. E. W. Dodwell, Esq., District Engineer, Halifax, N.S.; F. G. Goodspeed, Esq., District Engineer, St. John, N.B., and on application to the Postmaster at Annapolis Royal, N.S. R. C. Desrochers, secretary, Ottawa.

Fort William, Ont.—Tenders will be received up till September 4th, 1913, for an armory and drill hall, which the Government will build on a site donated by the city. Plans and specifications may be obtained from A. McNaughton, City Clerk.

Fraser River, B.C.—Tenders will be received up till September 30th, 1913, for the construction of jetty and dredging at the North Arm of the Fraser River. Plans and specifications may be obtained from the offices of C. C. Worsfold, Esq., District Engineer, New Westminster, B.C.; W. Z. Earle, Esq., District Engineer, Winnipeg, Man.; J. S. MacLachlan, Esq., District Engineer, Victoria, B.C.; J. L. Michaud, Esq., District Engineer, Postoffice Building, Montreal, P.Q.; J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto, Ont., and on application to the Postmaster at Vancouver, B.C. R. C. Desrochers, secretary, Department of Public Works.

+—Hamilton, Ont.—The Canadian Porcelain Company, of Hamilton, Ontario, have awarded the SMART-TURNER MACHINE COMPANY, Ltd., of Hamilton, Ontario, the contract for one of their automatic feed pump and receivers.

+—Island River, N.D.—W. J. POUPORE has been awarded the contract for dredging Island River. The contract price is $6,800.

Montreal, Que.—JAMES HOWDEN & CO., LIMITED, Glasgow, Scotland, have been awarded the contract to install a Wallsend-Howden patent system of oil burning in connection with the locomotive tube boiler at McGill University, Montreal.

The Hampton Sedimentation Tank

Used in connection with an electrolytic hypochlorite treatment, the process is **ABSOLUTELY ODORLESS** and the effluent is free from disease germs.

Nine years of operation in large and important installations in England have demonstrated that an effluent exceptionally low in suspended solids and as free from odor as the entering sewage may be obtained with The Hampton Tank.

The Hampton Tank reduces the cost of any subsequent treatment.

Write for leaflet showing construction ot the tank and explaining the special features of its design which make it particularly successful. This tank is not an experiment. It has been used for nine years with most satisfactory results, and has **PROVED** its efficiency and economy.

Leaflet on request.

Sterilization Co.
Union Building, Clinton Street
NEWARK, N. J.
Also engineers for the electrolytic treatment of water.

Montreal, Que,—A new grain elevator will be built by the harbor commission as soon as a suitable and convenient site has been decided upon.

New Westminster, B.C.—BROLEY & MARTIN, of New Westminster and New York, have been awarded the contract for the completion of the first unit of the north jetty at the Fraser River sandheads. The contract price is $83,500.

Ottawa, Ont.—Tenders will be received up till September 2nd, 1913, for construction of a concrete foundation and floor, St. Gabriel Shed No. 1, Lachine Canal. Plans and specifications may be obtained from the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Superintending Engineer of the Quebec Canals, New Birks Building, Montreal, Que. L. K. Jones, assistant Deputy-Minister and Secretary, Department of Railways and Canals, Ottawa.

Pembroke, Ont.—Tenders will be received up till September 2nd, 1913, for the construction of a new drill hall. Plans and specifications may be obtained from Town Clerk, Pembroke, Ont.; Director-General of Engineer Services, Ottawa, Ont., and also at the offices of the officer commanding the third Division, Kingston, Ont. Eugene Fiset, Deputy Minister.

Prescott, Ont.—Tenders will be received up till August 28th, 1913, for the construction of a single screw steel steamer. Plans and specifications may be obtained from the office of the Purchasing Agent of the Marine and Fisheries Department, Ottawa; at the offices of the Collectors of Customs, Toronto, Collingwood and Port Arthur, and at the Agencies of the Department of Marine and Fisheries at Montreal, Quebec, St. John, Halifax and Charlottetown. Alex. Johnston, Deputy-Minister.

▲—**Regina, Sask.**—Tenders will be received up till October 1st, 1913, for the supply of coal bunkers, ash hoppers, coal and ash conveyers and crushers. Plans and specifications may be obtained from E. W. Bull, Superintendent of Light and Power, Regina, Sask.

Sarnia, Ont.—The harbor improvements are being held up at the present time on account of the town councillors not being favorable to dredging in the bay, which is just above the water works intake pipe. It will cost the Government $50,000 for improvements.

+—**St. Catharines, Ont.**—The Corporation of St. Catharines have awarded the SMART-TURNER MACHINE COMPANY, Ltd., of Hamilton, the contract for a duplex pump.

St. John, N.B.—Tenders will be received up till August 21st, 1913, for rebuilding wharf. Plans and specifications may be obtained from Common Clerk's office, St. John, N.B. H. B. Schofield, Commissioner of Harbors, Ferries and Public Lands.

Vancouver, B.C.—The Amalgamated Drydock and Engineering Company, of Vancouver, is applying to the Department of Public Works for a subsidy for the construction of a floating drydock to cost $2,500,000. The dock will be capable of accommodating the largest class of vessels.

+—**Walkerton, Ont.**—Mr. JOSEPH SCHICKLER, of Deemerton, was awarded the contract for the erection of a big cement breakwater. The contract price is $6.30 a cubic yard, the total cost of which will amount to $1,000.

+—**Welland, Ont.**—The Canadian Steel Foundries, Welland, Ontario, have awarded the SMART-TURNER MACHINE COMPANY, Ltd., of Hamilton, the contract for a centrifugal pump.

CURRENT NEWS.

Brantford, Ont.—The steel work on the Grand Trunk Railway bridge over the Grand River is progressing. Another span has been taken down and a new steel span has been placed at the eastern end of the bridge.

Saskatoon, Sask.—R. J. Lecky Company, of Regina, has been awarded the contract for the construction of the Twenty-fifth Street bridge, which will be the fifth bridge to span the river at Saskatoon. The sum involved in the contract is in the vicinity of $400,000, one-third of which will be paid by the city and two-thirds by the Provincial Government. Work will commence immediately and will be completed about the fall of 1915. The structure will be of reinforced concrete. After work is properly under weigh, a gang of 150 men will be continually employed. Lecky's tender was the lowest received. The others varied considerably, the highest being $800,000.

PATENTS.

Below will be found a complete up-to-date list of patents recently granted to inventors in Canada and United States, which is furnished by Messrs. Fetherstonhaugh & Company, patent barristers, solicitors, etc.; head office, Royal Bank Building, 10 King Street East, Toronto. Offices in Hamilton, Montreal, Ottawa, Winnipeg, Vancouver and Washington, D.C., from whom all information may be readily obtained:—

Canadian Patents.

G. Weston, et al., display racks; P. Szumenski, breakers for cars; E. Heroux, windows; J. J. Richardson, disinfecting apparatus; A. B. Woonton, et al., holding cardboard boxes; W. J. Brennan, et al., ladies' under vests; H. Schindel, et al., attachments for cars; J. D. Clemence, vulcanizers; C. De Cazen, cigarette-making machines; P. Garant, combination hat and coat hooks; J. A. Houle, pastry cutters; A. Jeffrey, advertising devices; Z. Langlais, fountain brushes; J. H. Letourneau, cow trusses; J. McAninch, feed-water heaters for locomotive boilers; S. C. Matthews, educational devices; J. E. Menancon, animal traps; E. Menkin, deodorizing and disinfecting appliances; J. E. Sargent, brushes; H. H. Vaughan, appliances for locomotive cabs and tenders; H. Videbak, automatic air steam coupler attachments for railway cars; A. H. Woodworth, ticket wickets; H. Schindel, et al., signalling devices; J. Schwab, railway signals.

United States Patents.

G. L. Hogan, oil burner; T. McOuat, valve for pulp-pumps; J. W. Mowbray, carbureter.

MONTREAL LETTER

Montreal, August 16th, 1913.

Philadelphia advices say that the falling off in daily rate of production of iron in July, 82,601 tons per day, compared with 87,619 in June, was 5.7 per cent., much the heaviest since production turned downward, although the rate has really been declining since February.

In that month the daily average rate was 92,369, or at the rate of 33,800,000 per year. July daily rate was equivalent to 30,150,000 tons per year, a reduction of 10.8 per cent. from the high record of February, the daily average of which month was the greatest ever recorded. The heaviest calendar month was May, when production was 2,822,217 tons, and daily rate was therefore 91,039 tons. July production of 2,560,646 tons was the smallest for any month of the year and was 261,571 tons less than May.

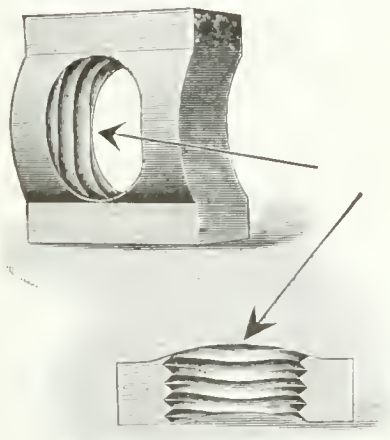
August will undoubtedly witness a continuance of curtailment in production. Sixteen furnaces went out of blast in July and those remaining in blast August 1, had daily capacity of 81,657 tons, compared with 88,020 July 1st. This would point to a reduction of about 2,450,000 tons in August, bearing in mind that actual production never quite reaches theoretical productive capacity. Production was affected adversely by the heat during July and this factor will probably be of smaller importance during the current month.

In the Montreal market, practically no change has taken place nor do iron and steel men look for any change of consequence for some time to come. The tightness of money is now undoubtedly the controlling factor. During the past few days, this tightness seemed to be giving way if one were to judge from the stock markets, but apparently the revival was only temporary and is apt to be succeeded by some re-action. In any case, it seems unlikely that there can be any marked improvement until the money situation alters materially, and an alteration of this character cannot be brought about over-night. It looks, therefore, very much as though buying will not recover very greatly.

Pig iron is moving in small quantities and there will be some recovery before the close of navigation. Throughout the market for iron and steel and products there has been very little alteration in price.

Carl Zeiss (London), Limited, of England, have made arrangements with E. R. Watts and Son, Canada, Limited, of Winnipeg and Ottawa, for the latter firm to act as sole agents for Canada for the sale of Zeiss surveying and engineering instruments.

Throw Away Your Keys and Cotter Pins



This cut shows an exaggerated curve in thread pitch—or more (in order to emphasize this feature) than is given in practice.

There is now no longer any need for them. They were good in their day, but have fulfilled their mission. The world moves and there is now a better way to keep nuts on.

The Grip Nut is the device to do it with. It requires no hole, slot or other change in the bolt and does away with the necessity for cotter pins, keys or other auxiliary fastenings.

The Grip Nut can be removed and put back on again without injury to the threads of either the bolt or nut. It starts easily with the fingers, and then can be tightened with a wrench.

Grip Nuts

Are being used by the millions on all kinds of machinery, elevators, conveyors, concrete mixers, steam shovels, bridge construction, motor trucks, automobiles, pumps, agricultural implements, etc. They are also being used in vast quantities by the leading railroads.

Universal use is the surest indication of satisfaction.

The secret of the efficiency of the Grip Nut is in the arch, and it is by means of this arch that the thread deflection is given, which enables the Grip Nut to lock on the threads of the bolt.

Manufacturers of machinery, from which it is important that nuts should not lose off, are now using Grip Nuts instead of the old style cotter pins and split keys, or double nut practice.

Grip Nuts are made in all sizes, square and hexagon.

We will cheerfully send catalogue and sample nuts on request. Mention size of bolt.

TENDERS CALLED FOR

THE COMMISSIONERS OF THE TRANSCONTINENTAL RAILWAY.

NOTICE TO CONTRACTORS.

TENDERS FOR LOCOMOTIVE AND CAR SHOPS AT ST. MALO, P.Q.

SEALED TENDERS addressed to the undersigned, and marked on the envelope, "Tender for Shops," will be received by the Commissioners of the Transcontinental Railway at Ottawa, Ontario, until 12 o'clock noon of **Tuesday, 2nd September, 1913,** for the construction and erection complete, in accordance with the plans and specifications of the Commissioners of a Locomotive and Car Shop repair plant at St. Malo, P.Q.

The plans, details and specifications, which will include the locomotive and car shops, the yard sewerage system and drainage system, yard water system, and the yard grading and track-laying, may be seen at the office of Mr. Gordon Grant, Chief Engineer, Ottawa, Ontario, and at the office of Mr. A. E. Doucet, District Engineer, Quebec, P.Q.

Persons tendering are hereby notified that tenders must be made on the printed forms supplied by the Commissioners. These may be had on application to Mr. W. J. Press, Mechanical Engineer, Ottawa, Ontario, or to Mr. A. E. Doucet, District Engineer, Quebec, P.Q.

Each tender must be signed and sealed by all parties to the tender, and witnessed, and be accompanied by an accepted cheque on a chartered bank of Canada, payable to the order of the Commissioners of the Transcontinental Railway for the sum of ($50,000.00) Fifty Thousand Dollars.

The cheque received from the party whose tender is accepted will be deposited to the credit of the Receiver-General of Canada, as security for the due and faithful performance of the contract, according to its terms.

Cheques received from parties whose tenders are rejected will be returned within ten days after the signing of the contract.

The right is reserved to reject any or all tenders.

By order,

P. E. RYAN,
Secretary.

The Commissioners of the Transcontinental Railway.

Dated at Ottawa, Ont., July 28th, 1913.

Newspaper inserting this advertisement without authority from the Commissioners will not be paid for it.—45825.

CAYUGA, ONT.

Sealed tenders will be received up to noon on the 16th day of September, 1913, by the undersigned at Cayuga, Ontario, for the construction of twenty-six and one-half miles of stone macadam road in the county of Haldimand.

The work will be let in three separate and distinct contracts, not necessarily to the same individual.

Tenderers are required to examine the localities of the work and are requested to be present at the opening of the tenders at 2 p.m., on Wednesday, the 17th day of September, 1913.

Plans and specifications may be seen at the office of the County Engineers, Messrs. Jackson and Kyd, Dunnville, or may be had from them on the payment of $10, which sum will be refunded on return of the documents.

Lowest or any tender not necessarily accepted.

T. A. SNIDER, K.C.,
County Clerk,
County of Haldimand,
Cayuga, Ont.

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

WELLAND SHIP CANAL.

SECTION No. 3.

NOTICE TO CONTRACTORS.

SEALED TENDERS, addressed to the undersigned and marked, "Tender for Section No. 3, Welland Ship Canal," will be received at this office, until 2 p.m., on **Wednesday, August 27th, 1913.**

Plans, specifications and form of contract to be entered into can be seen on or after this date at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Engineer in Charge, St. Catharines, Ontario.

Copies of plans and specifications may be obtained from the Department on the payment of the sum of fifty dollars. To bona fide tenderers this amount will be refunded upon the return of the above in good condition.

Parties tendering will be required to accept the fair wages schedule prepared or to be prepared by the Department of Labor, which schedule will form part of the contract.

Contractors are requested to bear in mind that tenders will not be considered unless made strictly in accordance with the printed forms, and in the case of firms, unless there are attached the actual signature, the nature of the occupation, and place of residence of each member of the firm.

An accepted bank cheque on a chartered bank of Canada, for the sum of $400,000.00, made payable to the order of the Minister of Railways and Canals, must accompany each tender, which sum will be forfeited if the party tendering declines entering into contract for the work at the rates stated in the offer submitted.

The cheque thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque of the successful tenderer will be held as security, or part security, for the due fulfilment of the contract to be entered into.

The lowest or any tender not necessarily accepted.

By order,

L. K. JONES,
Asst. Deputy Minister and Secretary.

Department of Railways and Canals,
Ottawa, 2nd August, 1913.

Newspapers inserting this advertisement without authority from the Department will not be paid for it.—46052.

CITY OF LONDON.

TENDERS FOR STEELWORK.

Sealed proposals addressed to the Chairman and Members No. 2 Committee will be received at the office of the City Clerk up to 5 p.m. on Thursday, 11th day of September, 1913, for the supply and erection of three 130 feet spans rivetted truss steel highway bridge over the River Thames, the substructure for which is already under construction.

Plans, specifications and all particulars can be had at the office of the City Engineer.

No tenders will be considered unless accompanied by a deposit cheque for 5 per cent. amount of the bid.

The lowest or any tender not necessarily accepted.

B. W. BENNETT,
Chairman No. 2 Committee.

Wm. N. ASHPLANT,
City Engineer.

(For further Tenders see page 86.)

When designing

structures do you pay sufficient attention to the various matters that govern insurance ratings?

Not only can you add greatly to the fireproofness of buildings by adopting our suggestions, but it is very likely that you can do so without the improvements costing anything ultimately. They will be paid for by the lower insurance rates.

Correspondence solicited. We have a staff of engineers and inspectors trained in this highly specialized line. Make use of our services.

In making sewer pipe

many pieces come from the kilns with imperfections. They are rendered imperfect by having pieces broken out of the socket or spigot end, or having fire cracks at either end or extending partly through the body of the pipe. Or they may be imperfect in shape, out of round or not straight; not thoroughly vitrified or glazed; or with blisters or scales blown off the outside. Such pieces cannot be classed as strictly first-class pipe. When buying pipe from us one can rest assured that we will never deliver pipe with imperfections such as above unless "seconds" are particularly asked for by the purchaser.

NOW READY

The Elements of Specification Writing

A Text-book for Students in Civil Engineering.

By Richard Shelton Kirby, C.E., Professor of Civil Engineering, Pennsylvania College; Member of the Society for the Promotion of Engineering Education. 8vo, vii + 125 pages. Cloth, $1.25 net.

A text-book on the art of specification writing. While intended primarily for the classroom, it will also prove of value to the young engineer in practice. Includes the fundamentals of a contract, particularly of a construction contract with its attendant plans and specifications concisely brought out.

FOURTH (Revised and Enlarged) EDITION

Treatise on Wooden Trestle Bridges and their Concrete Substitutes

According to the present practice on American Railroads.

By Wolcott C. Foster. 4to, ix + 440 pages, 180 figures, 76 full page plates. Cloth, $5.00 net.

This revision will prove of benefit and use, not only to those engaged in steam railroad work, but also to those engaged in electric railway work and to manufacturing plants having or desiring to construct elevated tracks for the cheap handling and unloading of materials.

FOURTH EDITION, Revised and Enlarged

Steam Power Plant Engineering

By G. F. Gebhardt, Professor of Mechanical Engineering, Armour Institute of Technology. 8vo, xvi + 989 pages, 605 figures. Cloth, $4.00 net.

The development of steam power plants has been so rapid during the past three years that it has become necessary to re-write the book. Particular attention is called to the chapters on Fuels, Combustion, Engines, Turbines, Condensers, Finance & Economics.

Note the reduction in price from $6.00 net to $4.00 net.

Steam Engineering A Text-book

By William R. King, U.S.N., Retired. Principal of the Baltimore Polytechnic Institute. 8vo, vii + 450 pages, 177 figures. Cloth, $4.00 net.

A text-book for students of universities and advanced secondary technical institutes.

Presents concisely the principles and constructive details of the make-up of a steam-power plant, together with such calculations as are necessary for a practical knowledge of steam engineering.

Tenders Called For

PROPOSED GOVERNMENT BUILDINGS, OTTAWA, ONT.

Architects are invited to submit sketch designs in a preliminary competition for the erection of departmental and courts buildings.

From the designs submitted in this preliminary competition, six will be chosen by the Assessors, the authors of which will be invited to submit more matured designs in a final competition, for which the five unsuccessful competitors shall each receive an honorarium of three thousand dollars ($3,000).

The author of the design placed first by the Assessors will be entrusted with the work which the Government intends carrying out at once.

The competition is limited to British subjects practising in the British empire.

The Government has appointed Mr. T. E. Collcut, Mr. J H. G. Russell and Mr. J. O. Marchand, as Assessors to act in its behalf.

The designs in the first competition must be delivered in Ottawa (carriage paid) not later than 12 o'clock noon, 2nd January, 1914, addressed to the undersigned.

Conditions for both competitions may be had on application to the undersigned, and at the office of the High Commissioner for Canada, 17 Victoria Street, London, England.

By order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, August 18, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—44890.

CITY OF REGINA, SASK.

Sealed tenders, registered and clearly marked on the outside of the envelope "Tender for Power-House Equipment," and addressed to the City Commissioners at Regina, Sask., will be received up till noon of October 1st, 1913, for the supply of:—

Coal bunkers, ash hoppers, coal and ash conveyers and crushers.

Price to be on equipment erected on foundation built by the City of Regina according to contractor's requirements.

A marked cheque for 5 per cent. of the amount of the bid, and made payable to the City Treasurer, City of Regina, must accompany each tender.

Specifications may be obtained from E. W. Bull, Superintendent of Light and Power, Regina, Sask.

The City Commissioners reserve the right to reject any or all tenders.

(For Further Tenders see page 84.)

Northey, T. H. Plummer, A. P. Holden. City Towel, Apron Supply and Laundry, $150,000. O. H. King, E. McL. Rowand, W. C. Johnston. Italian Courier Publishing Company, $40,000. G. Danovaro, L. Zaccaria, G. Colombo. Turbine Equipment Company, $40,000. J. L. Ross, D. J. MacLean, C. J. F. Collier. Buckham, $40,000 (fur dealers, etc.). J. P. White, Wasabika Binesott $1,000,000. Dillon, Parmenter, A. J. Thomson, W. S. Morlock. John A. McRae, $40,000 (ladies headwear and dress manufacturing). J. A. McRae, J. A. McRae, junr., F. W. Cooper. Real Estate Corporation of Canada, $40,000. H. M. Grills, J. C. Grills, W. H. Woulfe.

Refined to Definite Standards
BITUMEN 99%

MEXICAN EAGLE ASPHALT

TRADE MARK

Every Barrel Guaranteed Uniform
BITUMEN 99%

Mexican Eagle Paving Asphalt is specially adapted to the Canadian climate. It is not susceptible to changes in temperature. It will not mark in the hottest weather, nor is snow or ice likely to crack it. Dow and Smith, Chemical Engineers, say: "This is a very high quality of asphalt."

Every barrel of our asphalt is guaranteed to be uniform and according to analysis. This is the guarantee of our principals, the Mexican Eagle Oil Co. Limited, a Company that has over twenty-five million dollars working capital.

Mexican Eagle Paving Asphalt is superior in purity to Burmudez, Trinidad, Californian or any other asphalt on the market. It is a favorite also for its high cementing value and ductility.

We can also supply different grades of Mexican Eagle Asphalt for asphalt fillers, road binders, roofing asphalts, wooden water pipe coatings, waterproofings, etc. Also Durazzo Sicilian Rock Mastic Asphalt for sidewalks.

ANALYSIS
By DOW & SMITH, Chemical Engineers.

"Bitumen soluble in Carbon Disulphide	99%
"Bitumen soluble in Carbon Tetrachloride	99%
"Bitumen soluble in Penna naphtha boiling between 40° and 60° C.	78%
"Penetration at 77° F.	44
"Ductility unfluxed	22 cms.
"Penetration of Asphaltic Cement at 77° F.	50
"Ductility of Asphaltic Cement at 77° F.	45 cms.

"Remarks: This is a very high quality of refined Asphalt and is suitable in every respect for paving purposes."

TRANSPORTATION BUILDING — MONTREAL

Illustration below shows a portion of our Mexican plant in the Isthmus of Tehuantepec. Every structure in sight belongs to the plant, but a large portion to the left is unseen. The capacity was recently increased by over fifty per cent. We can get 75,000 tons of the world's very best paving asphalt from this plant in 1914 if the Canadian cities and towns require that quantity.

FOR SALE.—Complete Sewer and Water Contractor's outfit, including one Parsons' Trench Excavator, Trench Braces, Fire Pots, Pumps, etc. For price and terms apply to Navin Bros., Contractors, Moose Jaw, Sask.

GAS ENGINE, 8 h.p., for sale cheap; in first-class condition. M. Pullan and Sons, Bay and Wellington Streets, Toronto.

FOR SALE at a snap: 60-H.P. Cowan and Co. engine and 80-H.P. Cowan and Co. boiler. Write for particulars, J. F. Barnard and Son, Spencerville, Ont.

FOR SALE.—One second-hand Marion steam shovel; model 20; has seen very little service and is in fine repair. Also one second-hand Marion shovel; model 30; revolving; in good repair. Low price for immediate sale. Address, R. B. Stewart, Whitby, Ont.

FOR SALE

Plant of the Alberta Engineering Company, Limited, in Manchester Sub-division, Calgary, Alberta; building 96 x 34, equipped with electric power, complete machinery with individual motors for structural steel plant, made up as follows:—

High-speed Friction Saw 40 inch blade, electric drive.
Rock River Power Shear, belt driven, 32 inch gap.
Rock River Punching Machine, belt driven, 30 inch gap.
Stewart Drill Press, belt driven, up to 1½ inch dia. drill.
Landis Bolt Cutter, belt driven, up to 1½ inch bolt.
Power Hack Saw.
Jib-boom Derrick, 40 foot boom.
Allan Squeeze Rivetter, 18 inch gap, compressed air.
Blaisdell Air Compressor, belt driven, 8 x 8, with receiver and cooling tank.
Gardner Air Compressor, 6 x 6, mounted on truck, with motor drive.
Grinder, 24 inch mandrill, double head, belt drive.
Two 10 H P., 3 phase, 60 cycle, 220 volt motors.
One 15 H P., 3 phase, 60 cycle, 220 volt motor.
Two 5 H.P., 3 phase, 60 cycle, 220 volt motors.
One 2 H P., 3 phase, 60 cycle, 220 volt motor.
All with starting boxes.
Two 3 ton "Cyclone" Chain Blocks.
One 2 ton Chain Block.
Boyer Air Hammer, 8 inch stroke.
Cleveland Pneumatic Hammer, size 9.
Cleveland Pneumatic Hammer, size 6, with snaps and hose complete.

The foregoing may be inspected at the plant of the Alberta Engineering Company, located as above, at any time, any working day, and will be offered for sale as a going concern or in individual units.

CANADA Portland CEMENT

SOME men ask for so many bags of "cement"—

Others, more careful, say they want "Portland Cement"—

But the man who does the best work insists upon getting "Canada" Portland Cement—

And he looks to see that every bag bears this label

To specify Canada Portland Cement, is to introduce an additional safety factor into your calculations. Architects, contractors and engineers know the value of "making assurance doubly sure."

TRADE ENQUIRIES.

The following inquiries relating to Canadian trade were received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W.—A London correspondent is open to purchase supplies of old scrap galvanized iron wire, and would like to hear from Canadian firms in a position to ship large quantities.

From the branch for city trade inquiries, 73, Basinghall Street, E.C.:—An English firm resident in Trieste, Austria, reports a good opening for sulphite wood pulp both in Austria and Italy, and is desirous of securing the agency of a Canadian manufacturer who can make regular shipments. London reference. A Scottish manufacturing firm who are patentees of lock-joint cast iron piping for water and gas works invite inquiries from Canadian engineers responsible for drafting projects for municipal and railway work.

MARKET CONDITIONS

Montreal, August 16th, 1913.

Bar Iron and Steel.—Trade is reported active. Bar iron, $2.10 per 100 pounds; best refined horseshoe, $2.35; forged iron, $2.25; mild steel, $2.20; sleigh shoe steel, $2.20 for 1 x ⅜ base; tire steel, $2.30 for 1 x ⅜ base; toe caulk steel, $3; machine steel, iron finish, $2.25.

Cement.—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1.40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags repurchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight

Chain.—The market is quoted per 100 lbs. as follows:—¼-in., $5.65; 5/16-in., $4.70; ⅜-in., $4.00; 7/16-in., $3.65; ½-in., $3.45; 9/16-in., $3.45; ⅝-in., $3.35; ¾-in., $3.25; ⅞-in., $3.15; 1-in., $3.05.

Explosives and Accessories.—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron.—The market is steady. Prices, basis, 28-gauge, are:—Queen's Head, $4.40; Colborne Crown, $4.20; Apollo, 10¾ oz., $4.30. Add 25c. per 100 lbs. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge. American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe.—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $22.50 per ton; selected Summerlee, $22; soft Summerlee, $21.50 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron, number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19.25 to $19.50 per ton, on track.

Lath.—See Lumber, etc.

Lumber, Etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph Poles: seven-inch top, cedar poles, 25-ft. poles, $2 each; 30-ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce, 4-ft x 1½-in., mill run, $3 to $3.25; pine, 4-ft. x 1½-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2.10; XX, $2.40; XXX, $2.80.

Pipe.—Cast Iron.—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe.—Wrought and Galvanized.—Demand is fair and the market steady:—¼-inch, $5.50, with 64 per cent. off for black, and 49 per cent. off for galvanized; ⅜-inch, $5.50, with 64 per cent. off for black, and 49 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent. off for black, and 59 per cent. off for galvanized. The discount on the following is 73½ per cent. off for black, and 63½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 73½ per cent. for black and 63½ per cent. for galvanized:—2-in., $36; 2½-in., $57.50, and 3-in., $75.50; 73½ per cent. off for black, and 63½ per cent. off for galvanized; 3½-inch., $95; 4-inch, $1.08.

Toronto, August 20th, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron.—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel.—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates.—½-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes.—Orders continue active. Lap-welded, steel, 1¼-inch, 10c.; 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks.—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $13 to $15 per M., three grades.

Broken Stone.—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Rubble stone, 55c. per ton, Scbaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Wasbago, $2.50 per ton for small, and $1.15 for large, freight to Toronto, 60 cents.

Cement.—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot.—The market is lower at 15⅞ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps.—75c. and $1 per 100; case lots, 5,0000, 20 per cent. off.

Dynamite.—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¾ cents pound. 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1¼c. per hundred. For 10-case lots and over deduct ¼ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1¼ cent.

Fuses.—Electric Blasting.—Double strength, $3.50 per hundred, advance 54c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 54c. per hundred for each 2-in. wire additional.

Iron Chain.—¼-inch, $5.75; 5-16-in, $5.15; ⅜-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3.55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe.—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40.60; 6-inch, $52.64. Galvanied Pipe, ¼-inch, $2.86; ⅜-inch, $2.86 ½-inch, $5.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.51.

Lead.—Firmer, $5.25 to $5.50.

Pig Iron.—We quote Clarence at $24 for No. 3; Cleveland, $24; Sommerlee, $27; Hamiltoo quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar.—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate.—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Baogor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green, $6, with a prospect of advance. Dealers are fairly busy.

Sand.—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe.—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0.25	$0.40	$0.65	$1.00	$ 3.85
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00
Double junctions	1.25	2.00	3.25	5.00	16.25
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. H. traps	2.00	3.20	6.50	13.00	.....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes, 9 inches and under or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels.—Active.—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2.75 to $3 per 100 pounds. Extra for smaller sizes of angles and tees.

Sheet Copper.—22c. per lb.

Sheet Steel.—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized.—Apollo Brand.—Sheets, 6 or 8 feet long, 30 or 36 inches wide; 10-gauge, $3.00; 12-14-gauge, $3.00; 16, 18, 20, $3.30; 22-24, $3.40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 pounds. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin.—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel.—Jowett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates.—3-16-inch, $2.40 per 100 lbs.

Zinc.—Spelter.—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, August 19th, 1913.

Anvils.—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¾ to 10¾c.; anvil and vise combined, each $5.50.

Bar Iron.—$2.50 base.

Bars.—Crow, $4.50 per 100 pounds.

Beams and Channels.—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick.—Kiln run per M, $13; sewer per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland.—$2.40 to $2.50 per barrel.

Chain.—Coil, 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7-16, $4.75; ½, $4.50; 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5½c. Tie out, 70 and 10 per cent.

Copper.—Tinned, boiler, 26½c., planished 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent discount.

Dynamite.—$11 to $13 per case.

Galvanized Iron.—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20, $4; 18, $3.95; 16, $3.90; Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30; 22, $4.30; 20, $4.10 per cwt.

Iron.—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26-gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American, $5.15; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe.—Iron, black, per 100 feet, ⅜-inch, $2.40; ½-inch, $2.55; ¾-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7.80; 1½-inch, $9.35; 2-inch, $12.50; galvanized—½-inch, $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch.—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled.—3-16-in., $3.35 base; machinery, $3 base; share, $4.50 base; share crucible, $5.50, cast share steel, $7.50; toe calk, $4.50 base; tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel.—8½ to 15c. per pound

A weekly paper for engineers and engineering-contractors

SCIENCE IN THE DESIGN OF STREETS

NECESSITY OF REGARD FOR FUTURE NEEDS—ARRANGEMENT DEPENDENT UPON TOPOGRAPHY, PRESENT ACTIVITIES AND FUTURE OUTLOOK OF SURROUNDING TERRITORY—POINTS IN CONSTRUCTION OF PAVEMENTS.

By J. RUSSELL ELLIS,
Assistant City Engineer, Regina, Sask.

THE problem of proper street design is as broad and varied as any problem could well be. If the matter were always handled in a scientific manner and by a skilled designer there would be little excuse for writing this article. Too often, however, are the very underlying and essential points in the problem which require study and skilled judgment arbitrarily fixed by the legally constituted authorities in charge without proper advice, thought or knowledge. We have probably all seen the street which is too narrow or too wide for the use to which it is placed, in the first instance permitting of insufficient roadway room or width of sidewalk or both, and in the latter case causing an excessive cost of maintenance or suffering for lack of the same. Even when the width of the street is satisfactory the location is often ill-adapted to the fundamental requirements of the traffic to which it is subjected. Again, the width and arrangement of roadway, sidewalks and parking strips are stupidly fixed. Still again, the choice of elevation, gradients, kind of paving materials and facilities for storm water drainage are commonly noticeable as features of which improper treatment has resulted in inexcusable confusion.

The first step required to be taken in dealing with the problem in a scientific manner is a reconnaissance of the territory tributary to the street. For the purpose of this paper it will be assumed that our street has already been laid out and various improvements made upon the abutting property as is the case nine times out of ten when the engineer is given a hand in the design. A map drawn to a fairly large scale—not less than one hundred feet to the inch—should be provided with the street lines and all abutting property divisions accurately shown. This should be used in conjunction with a small scale map if available showing the streets and natural topographical features in the section of the city or town which is traversed by the street under consideration. After a careful study of the maps, in which possible changes in width or location may be noted, the investigation will be carried to the field. Here all improvements along the street will be sketched in upon the large scale map in approximate position; any apparent diversion of traffic to other streets and the reasons therefor will be noted, and any obvious errors or omissions in the map lines or topography will be observed. The general character of the use of the contiguous territory, such as business, manufacturing, residential, residential mixed with business and public use, will be tabulated with the limits of each. Some study of the work involved in improvement, such as the cutting down of hills and the bridging or filling of depressions, should also be made. It will probably be possible at this time to make use of the conclusions drawn from the first study of the maps and to correct them where necessary. Along with these studies a reliable traffic census will be required. For this work it will be necessary to decide to what extent of detail the conditions will warrant the investigations to go. Various forms for recording the observations have been devised and rules established which are available for reference but need not be blindly followed. Certain it is, however, that records should be taken at different times during the day, at different seasons of the year and during different conditions of the weather. Where heavy and fairly continuous traffic is encountered it will probably be advisable to have the reports cover the entire twenty-four hours of the day. Concerning the information necessary to record, Professor A. H. Blanchard has made the following classification:—

1. Differentiation between horse-drawn vehicle traffic and motor car traffic.

2. Division of each of these classes of traffic into pleasure and commercial traffic.

3. Subdivision of commercial traffic into loaded and unloaded vehicles.

4. Determination of the weight per linear inch of width of tire of all types of commercial traffic.

5. Subdivision of the two classes of horse-drawn vehicles traffic, dependent upon the number of horses.

6. Subdivision of pleasure motor car traffic upon the basis of weight and speed, since, in many instances, the greatest damage to certain types of roads is caused by seven-seat touring cars, limousines or laundaulets, travelling at speeds of 40 to 60 miles an hour.

7. Extraordinary character of local traffic; for example, traction engines hauling trailers, motor bus traffic, ice wagons, mill drays, etc.

It would be well to remember, however, that this classification was made for the study of road design in general, and it seems to the writer that some modification might be made when considering street design alone. At

any rate, it would be necessary to consider to what extent in any case it is practicable to carry the investigation. For instance, the classification number 6 might well, in many cases, be omitted, since it should be feasible to estimate an average weight and speed of the pleasure motor cars, considering that such cars are generally standardized as to weight and that the speed is limited by law. This average could be obtained accurately enough for our purposes, and would curtail the work involved in taking the census to a considerable extent.

From the data obtained in making these preliminary studies a general tentative plan can be made. This plan will include any changes in location from the original layout that may be considered advisable as well as any changes in width. The considerations governing choice in these respects will, of course, be the class and amount of traffic and the topography of the ground.

The next work in order will be the preliminary surveys to consist of a proper alignment of the street as decided upon for mapping purposes and the taking of elevations for cross-sections and profile. This work should be carefully and accurately carried out, and the records taken will, in the end, be used for estimating purposes. The methods involved in this work are simple and familiar to all engineers. Suffice it to say that sufficient levels are taken to determine accurately the amount of material necessary to be handled in grading the street for improvement and for fixing the grade to suit probable requirements and existing conditions. The plan and profile will then be placed on the same sheet of profile tracing linen. In general, the scales preferable for use in profiles are forty feet to the inch longitudinal and four feet to the inch vertical. The scale for the plan will then be made to conform to the longitudinal scale of the profile, and the one will be placed directly below the other. With this data collected, we are now prepared to begin the detailed scientific study of the problem, and it is this portion of the work which is too often sadly neglected.

The first consideration affecting the question of the proper width of the street should be its classification as regards present or probable future use. The usual classification is placed under three heads, viz.: main thoroughfares, secondary thoroughfares and residential streets. The classification may be carried farther under a number of sub-headings. The traffic census and an estimate of future development, after careful study of the tributary territory, will be used in making the classification. It will be necessary to determine as best we can what facilities will eventually be required for the purpose of rapid transit. In large cities and on certain streets our conclusions will cause us to provide for underground or elevated railways, in other places the surface street railway only will be necessary. With the estimate of the amount of this traffic it is not difficult to calculate the width necessary to provide for taking care of it. For instance, the width required for single track street railway operation is eight to nine feet and for double track from nineteen to twenty-one feet. The general traffic should, as far as possible, be kept off of the railway allowance. Other public utility accessories that present a probability of being required on the street, such as pole lines, pipe lines, conduits, etc., will require consideration as to how much width will need to be excluded from other uses for them. Then the necessity or desirability of considering the ornate side of the problem as affected by planting spaces or parking strips should be given its proper place as going hand in hand with the scientific design. It may be considered that a width of four feet will be necessary for planting one row of trees, but the widths and arrangement of these spaces should not be fixed until after the width of roadway, sidewalks, etc., have been determined in order that the correct division or breaking-up of the space may be made. It might be noted here that the practice of placing sidewalks against the curbs where the roadway is less than fifty feet in width results in an improper division of the space.

The width of roadway exclusive of street railway allowance is a vital feature of the design. This is the point where one of the greatest aids of the traffic census comes in, though we will need to estimate the width that will be necessary for all future requirements as well as those of the present time. This may not call for the entire width being covered with pavement at first, but the estimated requirements should be provided for. After we have made a careful estimate of the amount and character of the traffic the problem of supplying the necessary width for its accommodation is of a more elementary character. It should be remembered that the principal purpose of the street is to provide efficient means for the necessary movement of the public and the opportunity for transporting the commodities required by it. To accomplish this necessitates providing the proper width to prevent congestion or inconvenience. We will need to fix a definite width to allow each vehicle on the street. Some authorities advise a width of eight feet, others nine feet. It would seem that on account of the tendency toward motor cars of wide bodies that where a preponderance of motor traffic is to be taken care of, the greater width should be used. Where it is estimated that most of the traffic will be composed of horse-drawn vehicles eight feet is sufficient. For calculating the widths of sidewalks required two feet is assigned to each pedestrian. Care will need to be exercised here that places where many people gather and leave at certain fixed times do not overtax the sidewalks. In all cases where feasible, however, the widths of the improvements necessary for the present use only should be adopted, with provision made for increasing them from time to time as needed.

The question of limiting gradients requires to be gone into carefully. The points affecting our decision in this matter are the maximum loads to be expected in the street car, motor and horse-drawn traffic, climatic conditions causing slipperiness, the damage accruing to existing improvements along the street by cutting below or filling above the level convenient for their use and, in some cases, the desirability of having the floor levels of large buildings at a distance not too varying from the street pavement. We will also need to begin thinking at this point about the class of paving materials that will be used in the construction, particularly with regard to their slippery tendencies. The grades should not be too steep to prohibit the ordinary desirable heavy loads being transported economically unless the interest value of the cost of reducing them, including all damage to abutting properties, would exceed the loss in cost of transportation. This problem should be figured out in detail where it is evident that large expenditures will require to be made in order to get the desired grades. In general, we may consider that a maximum grade of five per cent. is a desirable limit upon heavy traffic streets, and this maximum should only be employed wherever absolutely necessary and at infrequent intervals. A possible way of reducing the rate of grade upon a street is to have the roadway wind from one side to another. This method, when used, will probably necessitate a greater width of street and a different arrangement of the parking scheme. In this connection it may also be well to consider making detours from the

straight line in order that bad hills may be skirted instead of being crossed directly over their summits. By these means a considerable saving in steep grades may often be effected. The minimum rate of grade, too, depends upon the class of pavement used. It must be sufficient to allow prompt drainage of the surface water into the catch-basins. The expedient, however, of what is known as false grading in the gutters will allow roadway, curbs and sidewalks to be laid with a level longitudinal grade, if necessary, but the gutters will have to have sufficient grade to create a flow of water. The minimum grade for this purpose should in no instance be made less than four-tenths of one per cent., and this should be used as sparingly as possible.

The choice of kind of paving materials to be employed in the construction involves a great number of considerations which, however, can be investigated along scientific lines. Experience has already established that certain materials are undoubtedly best adapted for certain purposes, and the results may be made use of without further investigation. For instance, no one denies that Portland cement is the proper material for any permanent street pavement base and for the sidewalks, and the truth is equally as much evident that certain materials for the wearing surface of the roadway pavement are adaptable under certain climatic conditions while not under others. In considering the pavement base, however, we shall need to design the thickness and proportions of the concrete to safely withstand the loads and stresses to which it will be subjected. Ordinary practice has held pretty closely to the limits of four and eight inches, varying with the nature of the traffic and the condition of the sub-base. It is advisable to make an analysis of the bearing power of the soil and the stresses which will be produced by the traffic in each particular case where conditions vary materially from other cases which have been investigated. The principal stresses induced in the base are due to climatic forces and the loads causing compression. Variation in temperature tends to cause disintegration by expansion and contraction of the concrete, and water tends to penetrate through to the sub-base, making it soft and reducing its bearing power. Therefore, the base must be designed so as to expand and contract without breaking the bond, and the water must be kept out by an impervious surface. The loads tend to push the pavement into the sub-base, and hence the base must have strength and rigidity enough to distribute this force safely. In general, the safe load which may be allowed for the sub-base is two or three tons per square foot. It is probably needless to say that the width of tires will be considered as to the manner of transmitting loads to the base.

In designing the pavement wearing surface for the roadway a greater number of considerations enter. First, in the way of stresses we have to consider forces caused by impact, shearing and suction, as well as compression and temperature stresses. The forces caused by impact are received by the wearing surface only, and hence the wearing surface should have sufficient resilience to absorb these forces without damage. Standard tests have been devised for use in this connection. Shearing is induced by the tractive power of the wheels of a self-propelled vehicle and the feet of horses. The wearing surface must have sufficient strength to resist this force, and must have stability enough to prevent its being torn away from the base from the same cause. Hence the study and testing of the bonding properties are obligatory. Suction forces result from the partial vacuum created behind a rapidly moving motor vehicle. The individual parts of the wearing surface must be held together in order to resist this force. Compression and temperature stresses will be handled in a manner similar to that outlined for the concrete base.

Second, a comparison of the value of the different wearing surfaces should be made with especial reference to cost, durability, maintenance, cleaning, traction resistance, slipperiness, sanitary qualities, noise and possibly other qualities made desirable by local conditions. The U.S. Office of Public Roads, working along these lines some years ago, collected reports from the engineers of a number of American cities. The results of this enquiry were published in the form of a table which is reproduced below. Under the percentage column the various qualities desired in a pavement are assigned proportionate values, the total being 100 points. The pavement ranking first under any given quality is given the full quality percentage, the rest grading down from this value in proper proportion.

The table is not given here in order that the results shown may be taken as applying to any particular case, but merely to suggest the proper procedure for the investigation. In any one problem certain conditions of a local nature are bound to enter.

Comparative Value of Different Pavements.

Pavement qualities.	Per-centage.	Granite.	Sand-stone.	Sheet asphalt.	Asphalt block.	Brick.	Macadam.	Creosoted wood.
Cheapness (first cost)	14	4.0	4.0	6.5	6.5	7.0	14.0	4.5
Durability	20	20.0	17.5	10.0	14.0	12.5	6.0	14.0
Ease of maintenance.....	10	9.5	10.0	7.5	8.0	8.5	4.5	9.5
Ease of cleaning	14	10.0	11.0	14.0	14.0	12.5	6.0	14.0
Low traction resistance ..	14	8.5	9.5	14.0	13.5	12.5	8.0	14.0
Freedom from slipperiness (average of conditions).	7	5.5	7.0	3.5	4.5	5.5	6.5	4.0
Favorableness to travel ..	4	2.5	3.5	4.0	3.5	3.0	3.0	3.5
Acceptability	4	2.0	2.5	3.5	3.5	2.5	2.5	4.0
Sanitary quality	13	9.0	8.5	13.0	12.0	10.5	4.5	12.5
Total number of points.	100	71.0	73.5	76.0	79.5	74.5	55.0	80.0
Average cost per sq. yd. laid in 1905		$3.26	$3.50	$2.36	$2.29	$2.06	$0.99	$3.10

Note: Favorableness to travel is dependent chiefly upon smoothness and freedom from dust and mud, secondarily upon the qualities composing "acceptability." Acceptability includes noise, reflection of light, radiation of heat, emission of unpleasant odors, etc. It chiefly concerns the pedestrian and the adjoining resident. Cost per square yard includes concrete, but not excavation, curbing etc.: except for macadam, which is not usually laid on concrete.

When the available and seemingly desirable pavement surfaces have been thus compared it will be possible to reject those which do not meet requirements and thereby reduce the field of investigation. With those which are considered suitable the final test will be that of economy. Careful estimates should be made of the initial cost, the annual cost of maintenance and the life of each. Then, using the prevailing rate of interest with the amount of capital required to do the work, we can soon determine which is the most economical material to use.

A vital feature in street design from the aesthetic point of view is the parking treatment. There is no doubt that the average engineer would benefit exceedingly in collaboration with the landscape architect in this phase of the work, when this is possible. Certain elementary considerations, however, may be kept in mind, and a careful study of this question should not be dispensed with.

It is desirable to have residential streets planted with trees and grass in the strips reserved for parking purposes. Ordinarily the most suitable plan to follow is to place these spaces between the sidewalks and curbs, between portions of the roadway pavement where the space is available and, where the building line is at or near the street line, to have a space between this and the sidewalk. Trees should be planted in straight lines as a rule, twenty to thirty feet apart in a row, and the grass should manifestly be carefully cultivated. The selection of the kind of trees will be governed by local conditions, but the rapidly growing varieties are generally preferable. Low, dense growing trees, such as evergreens, are not often suitable for the purpose. They should produce a good shade and be shapely, the size being regulated by the available space and the proximity of buildings. It will be understood that certain varieties of trees will be unsuitable for urban planting on account of the condition of the atmosphere and the environment of surrounding improvements.

No one who is familiar with the methods of dealing with the various phases of the problem of street design as has been outlined will gainsay that no small amount of detailed effort will be involved in proceeding along these lines. It will be evident, however, that the results of the investigation of certain points will be applicable to the design of all streets in one town or city. Still other features will be similar when they apply to streets of like use throughout the municipality, and a majority of the results will coincide when relating to all of the streets of one classification within a limited territory. It should be borne in mind that the design of a street, when once executed, will be in a large measure permanent, and that countless numbers of users far into the future will suffer from any of the original defects. The economical side of the problem alone should appeal to all citizens, for not only will traffic be inconvenienced and made more costly, but abutting and nearby property values will be affected, and the community as a whole will be the loser in proportion to the enormity of the defects.

After all, the principal considerations are practically fundamental. When the reconnaissance and the preliminary surveys have been made, and the observations taken and data collected for determining width, limiting gradients, kind of paving materials and parking treatment, the sound judgment and knowledge of the competent designer, gained from study and experience, enable him to evolve a correct, scientific plan. There can be no excuse for any other.

A USEFUL ADDITION TO INDUSTRIAL MATERIALS.

A remarkable new material to take the place of hard fibre, glass, porcelain, hard rubber, built-up mica, pressboard, rawhide, moulded compounds, etc., has been developed by the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa. It is known as Micarta.

It is used for commutator bushings and brush-holder insulation, as noiseless gear blanks, as conduit for automobile wiring, as spools for sparkcoil and magnet windings, for refillable fuse tubes, for wireless coil separators, for arc shields in circuit-breakers, for water-meter discs, etc.

Micarta is a tan-brown colored, hard, homogeneous material having a mechanical strength about 50 per cent. greater than hard fibre. It can readily be sawed, milled, turned, tapped, threaded, etc., if a sharp pointed tool is used and the work done on a lathe. It can be punched only in thin sheets and cannot be moulded. Micarta is not brittle and will not warp, expand, or shrink with age or exposure to the weather but takes a high polish, presenting a finished appearance.

Two grades of the material are made. The grade known as Bakelite Micarta will stand a temperature of 150 degrees C. (300 degrees F.) continuously, or 260 degrees C. (500 degrees F.) for a short time. It is infusible and will remain unaffected by heat until a temperature sufficient to carbonize it is reached. Heat will not warp bakelite Micarta, and it will stand an electric arc better than hard fibre, hard rubber, built-up mica, or any moulded insulation containing fibrous or resinous materials. Its coefficient of expansion is low, being approximately .00002 per degree C.

Bakelite Micarta is insoluble in practically all of the ordinary solvents such as alcohol, benzine, turpentine, and weak solutions of acids and alkalis, hot water and oils. It is indifferent to ozone—an advantage over hard rubber, resins, etc., for electrical purposes. It is non-hydroscopic and impervious to moisture.

The other grade, designated as No. 53 Micarta, has the same mechanical and electrical properties as the Bakelite Micarta, but differs in its chemical and thermal properties. The plain Micarta behaves towards chemicals and heat very much as an ordinary resin. This grade is not used in plate form.

INFLUENCE OF METALLOIDS ON CAST-IRON.

A paper by H. I. Coe before the Iron and Steel Institute shows tests of 54 alloys, containing carbon 3.0, silicon from 0.4 to 2.24, manganese from 0.14 to 2.22, sulphur from 0.11 to 0.45, and phosphorus from 0.30 to 2.88 per cent. The author's conclusions are:—

Silicon decreases the strength and hardness of cast-iron, owing to its effect in promoting the decomposition of iron carbide.

Manganese to the extent of 0.5 per cent. softens silicious gray irons, owing to its effect on the condition of the carbon: the strength is increased by the addition of manganese.

Influence of sulphur is largely determined by the silicon present. Carefully controlled, it should be of considerable value to the iron founder in mixing his iron for any particular purpose.

In the absence of manganese, and with about 2 per cent. silicon present, very strong gray irons may be obtained if the percentage of sulphur be judiciously raised.

Phosphorus, up to about 1 per cent., is useful. It gives fluidity, slightly increases the strength, and also slightly diminishes the hardness of the metal. A higher percentage gives a hard, brittle material.

A 150-FOOT ARCHBRIDGE WITH SUSPENDED ROADWAY IN REINFORCED CONCRETE.

By V. J. Elmont, B.Sc., A. M. Can. Soc. C.E.

THE bridge described below (Fig. 1) carries a 14-foot 8-inch roadway and two 2½-foot sidewalks. It is calculated for a load of 120 lbs. per sq. ft. uniformly distributed and an additional load on the roadway of one road roller, weighing 30,000 lbs.

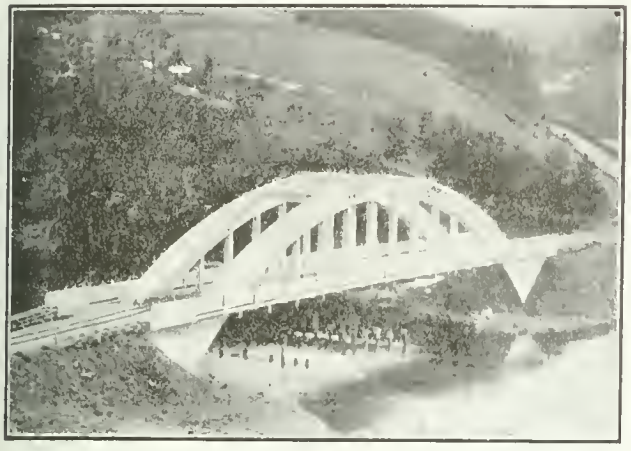

Fig. 1.—View of Finished Structure.

The macadamizing of the road rests on a crosswise reinforced slab, which again is supported by the floor-beams, spaced 9 ft. 10 in. centre to centre, and stringers. These are placed in the planes of the two archgirders and in the centreplane of the bridge. The sidewalks are supported by cantilevers from the floor-beams. The load from the floor is carried over to the arches through hangers.

The statical computation for the arches is made as for arches without hinges and by employment of influence lines. As basis for the figuring was used an allowable tensile stress in the steel of 14,000 lbs. per sq. ft. and

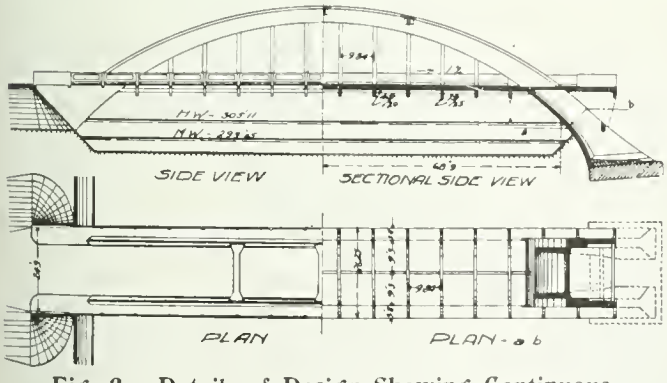

Fig. 2.—Details of Design Showing Continuous Arch-girders.

compression stress in the concrete of 550 and 700 lbs. per sq. ft. for roadway and arches respectively. Special care was taken in the investigation of the stresses due to change of temperature, which plays quite an important part in long-span arches with fixed ends, though, of course, much smaller than for a steel arch, as the conductivity of steel is much higher than that of concrete. Fifty degrees F. was considered as an average temperature at the time the bridge was constructed, and the limits of the temperature of the concrete in the finished structure were taken as 10° F. and 80° F. By this assumption the maximum bending moments produced by the live load and dead loads were increased by 20% at the crown and 69% at the springing line. This proves once more that the approximate figuring usually employed by designers without knowledge of calculating statically indeterminate structures, is nothing less than a menace to safe construction. As result of the statical computation the necessary depth at the crown of the arches was found to be 4 ft. and the width 2 ft. 2 in.

The usual design of placing the tie-rods for the arches in the roadway slab was not employed in this case, owing to the high value of the maximum horizontal pressure (290 tons for each arch). It would have been difficult to arrange the steel, necessary to resist this great pull, in the longitudinal beams between sidewalks and roadway, and also to ensure a safe connection between tie-rods and arches. The arches are stiffened by means of three cross T-beams, placed at their crowns.

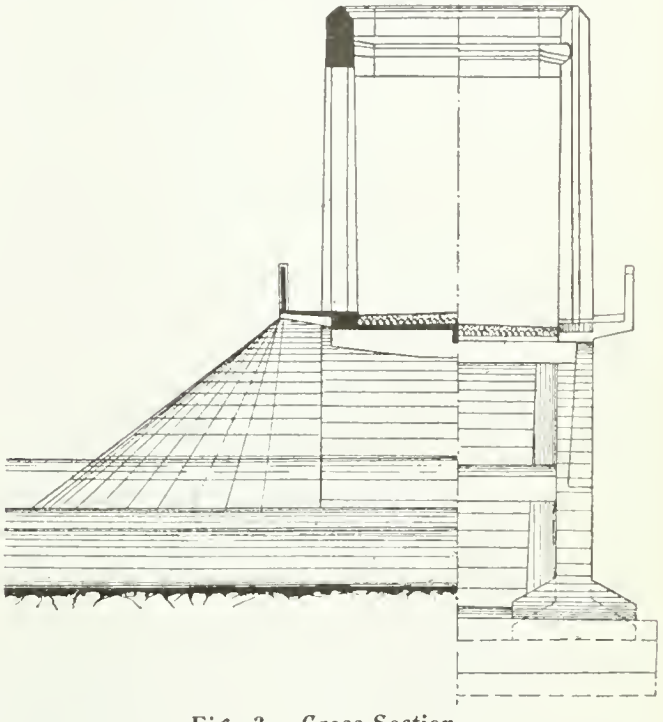

Fig. 3.—Cross-Section.

A somewhat unusual, but very economical, design, as compared with the solid concrete abutments, was employed for the abutments. The arch-girders are continued through the roadway to meet the foundation slab, which extends under both arches. (Fig. 2). Between the arches, and having the same curvature, a slab is constructed which, together with the extensions of the arches and two triangular wing-walls resting on the arches, form a container for the earth filling. The wing-walls and the arches are tied together by two cross-beams in each abutment. (Fig. 3).

The quantity of coal used for coke-making in the United States in 1912 was 65,485,801 short tons. The coke produced from this coal amounted to 43,916,834 short tons, valued at $111,523,336, besides large quantities of gas, tar, ammonia, etc., as by-products from the 11,048,489 tons of coke produced in by-product ovens.

ROAD MAINTENANCE IN ENGLAND.*

By Charles Vawser, A. M. Inst. C.E.I.

IT is generally accepted that municipal engineers can construct the best and most suitable roads for their particular districts, and, provided they have a free hand in the choice of materials and so forth, they can so construct them that they will be efficient and, at the same time, economical to maintain; but, unfortunately, in the case of main roads, and particularly old turnpike roads, many are found to be without efficient foundation, and the extent of their durability or life is limited to the surface or covering crust.

Foundations should be sound and solid in construction, so that they may withstand the weight, wear and tear of the present and future traffic, and, in addition, act as a protector to the surface against the many unknown evils which from time to time arise from underground air, fluctuating water levels, and other matters which have more or less evil effects, according to the chemical composition and geological construction of the material used.

There are several kinds of stone which wear better and longer in one district than in another. Frequently the users are at a loss to know the cause of this, but if one persists in his efforts to ascertain the failure he may find it comes more from underground sources than is usually realized.

The surface of the roads is one of the most debatable subjects that has ever been before the country, and not only is it debatable in every way, but it is also most fascinating on account of the many changes that are daily occurring due to mechanically propelled vehicles using the highways, which are increasing both in weight and number.

The writer eighteen years ago constructed roads with a surface of Welsh granite heated and mixed while hot with tar and pitch laid to measure 4 in. thick when consolidated, and he has no cause to change the opinion then formed that where macadamized roads are to be constructed, a bituminously constructed surface is the most efficient, sanitary and economical to maintain, provided it is on a good solid foundation.

It remains to be seen how long the present waterbound road will hold its position when modern circumstances demand a road of more homogeneous construction.

Cost and Maintenance.—The cost of making and maintaining highways is a most important and responsible obligation to all highway authorities, and while they all have to "pay the piper," unfortunately they are not always in a position to "call the tune," because they cannot regulate the class of traffic using the roads.

The cost is not so keenly felt in urban districts and towns where the roads from the first laying out are usually well constructed, and as the districts prosper and develop the increasing rateable value corresponding with such development prevents them from feeling the pinch of poverty to the same extent as in rural districts and large agricultural county areas where there is comparatively no increase in development.

In rural districts and county areas there are frequently long lengths of roads to maintain, through poor, agricultural districts, and their efficient upkeep is a source of grave anxiety to those in control on account of the great amount of touring traffic using the roads, and for which there is no return. The cost of maintenance falls very unfairly and unjustly upon the shoulders of highway authorities who have to maintain important trunk roads which, by their geographical position, form a connecting link from one centre of industry to another.

Until quite recently all roads were waterbound, and many mainly repaired with water binding; these, when dry, have been surfaced with a bituminous or tar coat. This undoubtedly prolongs the life, but unfortunately trunk roads leading from town to town are placed at a considerable disadvantage owing to it not being practicable to close the road until the bituminous material has become "set," with the unfortunate consequence that much damage is done. Furthermore, many roads are narrow, thus making it more or less impossible efficiently to carry out the work upon one half of the road and allow it to "set" before turning the traffic on to it.

Another point which the surveyor has to consider is the weather, and in this uncertain climate he endeavors to carry out the greatest amount of work when climatic conditions are most favorable.

This surfacing or tar-painting is both efficient and economical so far as it has gone, and has been suitable where the traffic was light. It is apparent that, while it may be suitable at present, the day is not very far distant when the surface of the tar-painting will have to be superseded by something more substantial. Circumstances are changing day by day, and one may anticipate future development of traffic in ratio to the progress of the last few years; consequently it seems obvious that motor and mechanical vehicles will increase as time proceeds. Should this prove to be the case, the annual cost of roads will become a serious matter to the authorities responsible for their maintenance.

When such eminent men as Sir John Macdonald state "the money value of good roads to the nation is enormous," and Sir George Gibb states that good roads constitute "the basis of national prosperity," it is apparent that good roads are appreciated; but up to now neither the "nation" nor "national prosperity" have paid their just proportion towards maintenance. It is well known that our highways were the foundation and nursery for developing the mechanical traffic during its infancy, which has now entered into a stage of prosperous commercialism, creating an enormous burden upon the local ratepayer without equal contributory advantage; and thus it appears a great misfortune that legislation should have limited the powers of the Road Board to contributing "towards" the cost of improvements.

Should (as predicted) the motor and mechanical vehicles increase, many highways will have to be reconstructed with stronger foundations according to the strata supporting them, the surfaces will have to be efficiently drained, made dust and waterproof with bituminous material of such thickness as will stand the heavy mechanical traffic without fracture, the fast motor traffic without ill effects from vacuum, and, at the same time, form a good foothold for horses and other animals. This will entail great expense, and it is to be hoped that this reconstruction necessitated by modern and future traffic will be met by monetary grants for capital reconstruction, and annual maintenance payments from the industries which have placed the obligations upon the authorities responsible for the efficiency of the highways.

*From a paper read at the Annual Meeting of the Institution of Municipal and County Engineers, Great Britain.

THE TOR HILL RESERVOIR, REGINA

DETAILS OF DESIGN AND CONSTRUCTION OF ONE OF REGINA'S TWIN RESERVOIRS FOR WATER SUPPLY—CONNECTIONS FOR INLET AND OUTLET MAINS—ITEMS OF COST.

By R. O. WYNNE-ROBERTS, M. inst. C.E., M. Can. Soc. C.E., F.R. San. Inst.,
Consulting Engineer, Regina, Sask.

THE city council of Regina, on the recommendation of Mr. A. J. McPherson, then city commissioner, now chairman of the Provincial Board of Highway Commissioners, decided to adopt a scheme which the writer had submitted, whereby an ultimate daily supply of ten million gallons of water can be made available, at an expenditure of about $2,000,000.

Such scheme included two five-million-gallon reservoirs. The construction of the first of these was commenced last summer, but owing to unforeseen delays in the supply of certain materials, it was found impossible to complete the work before the winter had set in. Immediately it was safe to proceed in the spring, the structure was finished as quickly as possible, and the reservoir has now been in use some four months. No signs of defects have been observed and the depth of water has been maintained at about 23 feet for about a month.

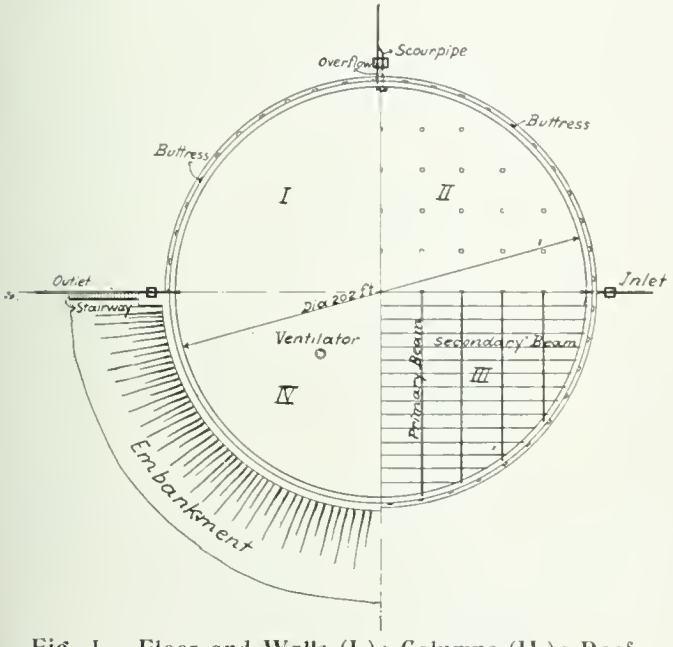

Fig. 1.—Floor and Walls (I.); Columns (II.); Roof-Beams (III.); and Cover (IV.).

Tor Hill reservoir is 202 feet in diameter, holds 25 feet depth of water, and its capacity is five million imperial gallons. This reservoir is circular in plan, reinforced concrete, and is located on a hill close to Boggy Creek waterworks, at an elevation of about 105 feet above the city; the top water line being about 120 feet above Regina level. It is so situated that it will answer in connection with future extensions of the water collecting works into five other watersheds.

The following is a description of the work as carried out:—

Excavations and Embankment.—The excavations averaged 9½ feet deep, the material removed was of a heterogeneous character, common to glacial formation, ranging from fine sand to heavy clay. This was excavated by horse-drawn wheel scrapers and the material deposited at convenient points, to be afterwards utilized in forming an embankment round the reservoir, in which work ordinary scrapers were employed. The quantity handled was about 12,500 cubic yards.

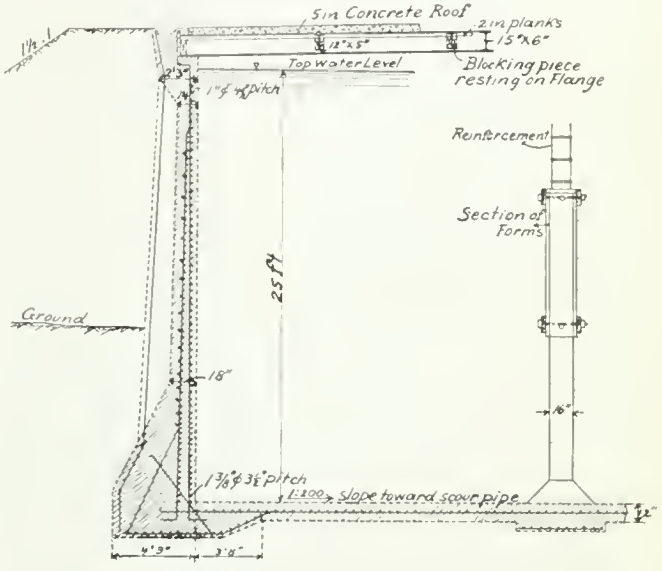

Fig. 2.—Section Through Wall, Roof and Base.

Footings of Walls.—The footings were first laid. They are one foot lower than the underside of the floor, except where the pipe connections are located, where the thickness was made two feet beneath the underside of the pipes. The footings extend for a distance of 3 ft. 8 ins. from the inner face of the wall under the floor, and are reinforced with half-inch round bars laid radially and circumferentially, and also a diagonal brace laid radially, at six-inch centres so as to form a strong tie between the wall and the floor.

Floor.—The reservoir floor is 12 inches thick, having a crossfall of one foot to the scour pipe, which is laid to a sump-hole at a depth of 2 ft. 3 ins. below the floor level. The floor was laid in two layers, each six inches thick, and between them were laid half-inch mild steel bars at six-inch centres, in two directions, at right angles to each other, tied together at every fifth intersection in one way and at every intersection in the other direction. The top surface of the concrete was worked to a fine close texture.

Columns.—There are 69 reinforced concrete columns, each 16 ins. by 16 ins., supported on truncated pyramidical bases 4 ft. by 4 ft., and 1 ft. 3 ins. high, which, with 6-inch sub-base, form an integral part of the floor. The sub-base was reinforced with half-inch bars laid at six-inch centres in cross directions.

The columns are reinforced with four ¾-in. round bars tied by 1 in. by 1/16 in. hoop iron links at 10-in. intervals. Where the bars join the base they are inserted into wrought iron tube sleeves one-quarter inch larger in diameter and grouted with neat liquid cement. After the bases had set these rods kept the forms from rising when they were filled with wet concrete.

The forms for the columns were made in three sections built of two-inch planks with 4 ins. by 4 ins. cross pieces at three feet centres and held together by ⅝ in. bolts. Each section was numbered so that three forms made a complete column. Sufficient forms for twenty

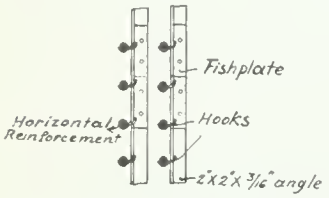

Fig. 3.—Standard and Hooks.

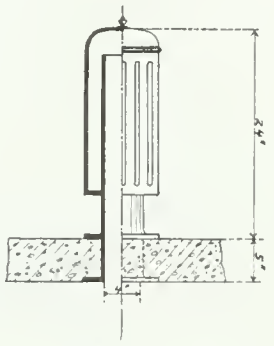

Fig. 4.—Ventilator.

columns were made and these were therefore used at least three times. These forms were assembled on the ground and hoisted up and lowered over the rods by means of a light gin pole on a monkey derrick built of skids. Lumber 2 ins. by 8 ins. was used to build up the derrick, and this was moved fom column to column by the men. The columns were braced by one-inch boards tied to the wall forms and were plumbed to assure the perpendicularity of the lower forms; the other forms were held in place by two bolts holding the second and third sections down to the one already filled in. One section about 9 feet high was filled each day.

Wall.—The wall is 57 inches thick at the floor level, while seven feet above the floor a steep batter on the outside reduces it to 18 inches, and from this point it tapers to 14 inches at the top water line. The wall then corbels out to allow a base for the roof beams and for a rain-water gutter. In the original design the wall was to be 9 ins. thick at the top and 14 ins. at a height of 5 feet above the floor, with three external reinforced concrete rings placed at points of equal pressure, to provide extra strength, as the work would be carried out under somewhat unusual conditions, but, owing to the delays already mentioned, it was deemed expedient to alter the design by eliminating the rings and thickening the walls by an equivalent volume of concrete and steel, so as to simplify the construction and thus expedite the work. The inside face of the wall is vertical.

The horizontal reinforcement in the wall was designed to take up the tensional stresses proportional to the varying depths of water. At the floor level there are two 1⅜-in. round bars at 3 ins. centres, curved to template to fit the curvature of the wall, and at the top 1 in. at 4½ ins. centres. These bars are held in place by 2-in. by 2-in. by ¼-in. angle steel standards in which holes were drilled at prescribed distances apart and ¼ in. steel hooks inserted to clip the rods. Such standards are 3 ft. 6½ ins. apart along the perimeter of the reservoir, and fixed so that there are 5 ins. of concrete between the horizontal steel reinforcement and the water face at the bottom, and 3 ins. at the top. This method of placing and fixing the horizontal bars resulted in a firm and satisfactory frame work which could not be disturbed when the men were placing the concrete.

The vertical reinforcement consists of half-inch bars at 8½ ins. centres, and are tied to the horizontals by black wire at every fifth intersection vertically and at each intersection on the fifth rows horizontally.

There are 45 buttresses spaced at 14 ft. 2 ins. around the outside of the wall. These buttresses are 2 ft. wide and project beyond the 14-in. wall at the top about 11 ins. and die out at the base. These are reinforced vertically by half-inch rods, spaced 4 ins. apart.

The walls, etc., were built in courses about 12 ins. high. Exery horizontal and vertical joint was thoroughly cleaned before the next layer of concrete was laid. Any concrete work which had been standing twenty-four hours or more had the laitance removed by picks, wire brushes, and plenty of water, so as to ensure a thoroughly sound bond. The concrete was well worked into the spaces between the steel rods, etc.

On the completion of the work, the wall, floor and columns were painted with hot liquid bituminous asphalte and afterwards limewashed.

The timber work necessary to form the internal surface of the wall consisted of bents erected about 14 ft. apart; the girts were spaced every five feet and on each row of girts were placed 6-in. by 6-in. beams. The one facing the studding had a segmental piece nailed on to its face to form the curve. On the top of the 6-in. by 6-in. timbers was built the runways or gangways which served to transport the materials. As the wall was built up to the level of the runways the timber work was made higher so as to command the next tier of concrete work.

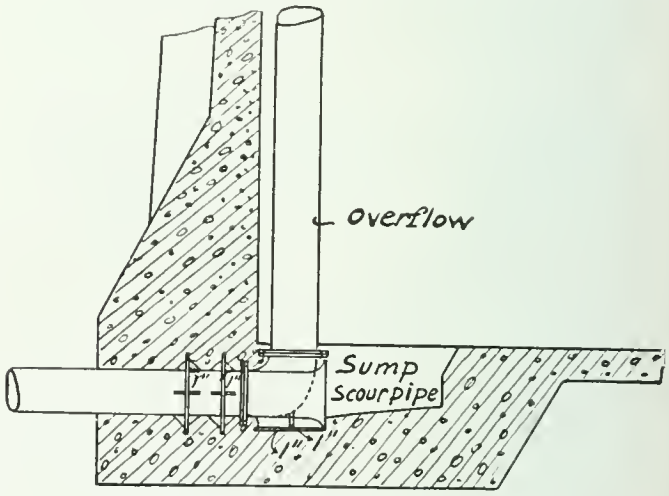

Fig. 5.—Overflow and Scour Pipe.

Roof.—The roof is constructed of 15-in. by 6-in. by 60-lb. rolled steel primary beams, cut to fit the 20-ft. spans and resting on the columns which are 20 ft. apart each way. The secondary beams are 12-in. by 5-in. by 31-lb. rolled steel joists fixed at 6 ft. 8 ins. centres and attached to the primary beams by angle iron brackets. The whole of the roof beams were rivetted together. The cover of the roof consists of 6 ins. concrete, reinforced with half-inch steel bars laid crossways at 6 ins. centres. The roof has a dome formation, being twelve inches higher at the centre than at the perimeter. The surface of the concrete was washed with hot liquid asphalte to prevent frost disintegrating the same.

Rolled steel joists were selected for the roof construction, as it would otherwise mean erecting false timber work to a height of 27 ft. to support the reinforced concrete beams. With the steel joists, however, the forms rested on the flanges, and this was a simpler and equally effective mode of construction.

The steel joists were elevated to the roof level by means of a fixed boom attached to the hoisting tower, which was used to raise the concrete and then landed on loose dollies and run within reach of a derrick. This placing derrick was built of 6-in. by 6-in. timber in the form of a double boom traveller, having a reach of 60 ft. when both booms were spread. It was slid along greased rails and carried a set of chain blocks at the end of each boom.

There are four cast iron ventilators in the roof.

Pipe Connections.—The 16-in. inlet and outlet pipes are placed diametrically opposite, and the overflow standpipe, and the scour outlet, which are together, are located half-way between the inlet and outlet. The overflow standpipe is held in place by 4-in. by ½-in. stays anchored into the wall.

All castings fixed in the concrete were uncoated and had puddle rings cast on, to prevent any water finding its way along the outside of the pipe. These rings are 6 ins. wide and 1 in. thick, strengthened by brackets 1 in. thick. All inside pipes have bell-mouths. The inlet and outlet pipes stand 6 ins. above the floor level.

All valves are located outside the reservoir, and enclosed in reinforced concrete manholes, measuring 3 ft. 6 ins. square at the top, and 3 ft. 6 ins. by 4 ft. 6 ins. at the valve level. The mains leading to and from the reservoir are of ample size to deliver at least five million gallons per day, and of such dimensions as to fit in with future extensions.

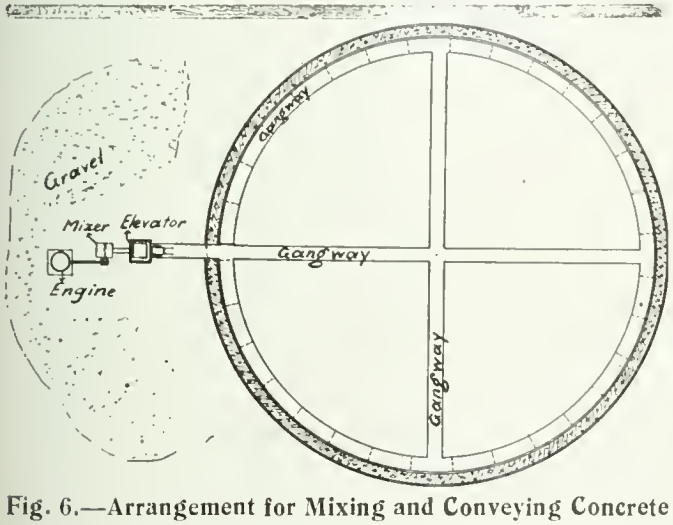

Fig. 6.—Arrangement for Mixing and Conveying Concrete

Wrought iron step ladders built of 4-in. by ½-in. stringers 18 ins. apart and ¾ in. rungs. The ladders are fixed into the concrete work at the top and bottom.

Reinforced concrete stairways are built at opposite points of the diameter to afford access. Stringers, 5 ft. apart, 15 ins. by 6 ins., and the treads are built monolithic and reinforced with half-inch rods lengthways and crossways.

Steel Reinforcements.—All bars or rods are medium steel, having an ultimate strength of 60,000 pounds per sq. in., and an elastic limit of not less than one-half of the ultimate strength, and elongate not less than 22 per cent. in eight inches, and bend cold 180 degrees round a diameter equal to the thickness of the piece tested, without fracture on the outside of the bend.

Steel bars were joined together by overlaps equal to forty times their respective diameter and tied with black wire. The working stress on the steel was limited to 15,000 pounds per sq. in. tension.

Portland Cement.—All the cement had to comply with the specifications prepared by the Canadian Society of Civil Engineers as revised in 1911, and the methods of testing were as near as possible those referred to in such revised specifications.

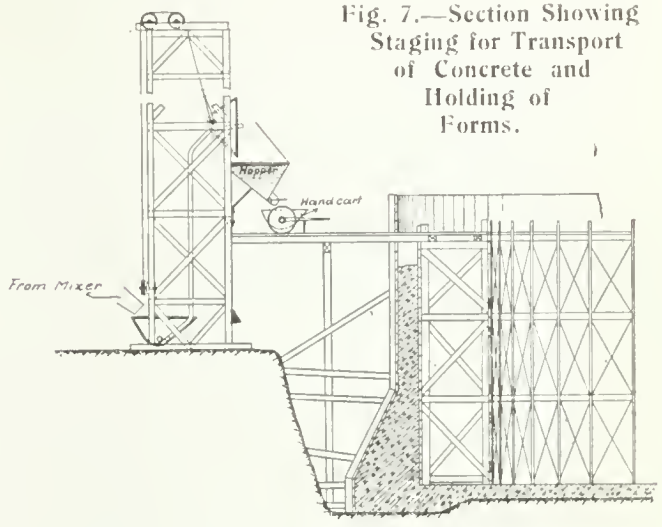

Fig. 7.—Section Showing Staging for Transport of Concrete and Holding of Forms.

Concrete.—The concrete was specified to be as follows: Floors, columns and wall, three parts of broken stone and gravel, one and one-half parts of sand and one part cement. The mass work round the pipes, in the valve chambers and in the roof cover were to be four, two and one, respectively.

The pit gravel obtained close-by, however, was found to conform fairly close to the specified proportions that a mixture of one cement to five pit gravel was substituted, care being taken to add more cement when necessary. About 3,400 cubic yards of concrete were laid. The limiting compressional stress in concrete was 500 pounds per square inch.

Mixing and Placing Concrete.—The concrete was mixed in a ¾ cubic yard Smith mixer, steam-driven. The concrete was mixed wet and was elevated by means of an Insley automatic roller hoist from the bottom into an Insley receiving hopper at the top, situated a few feet above the level of working operations from time to time. The concrete was then discharged into hand-drawn concrete hopper carts and wheeled over the gangways to all parts of the work. As the work proceeded the hoisting tower, gangways and forms were extended upwards.

Miscellaneous.—A Ham Baker water level indicator is being fixed to indicate the varying water level and by electric transmission to record the same at the Barton Pump House, half a mile distant.

A 20-in. by 10-in Simplex Venturi meter supplied by Messrs. Francis Hankin & Company, has been installed on the delivery main to the reservoir and near to the above pumping station. This meter automatically records the quantity of water pumped and also registers the total volume.

Supplies.—The ½ in. and ¾ in. steel rods were supplied by the Provincial Steel Company, of Cobourg, Ont.; Other steel was supplied by the Western Steel and Supply

Company, of Regina; cement by Canadian Cement Company, Calgary; cast iron by the Canada Iron Corporation, and the concrete machinery by Mussens, Limited, Winnipeg.

Some Itemized Costs.—The following are some of the itemized costs: Cast iron pipes, class C, 2¼ cents per lb.; special castings, 5 cents; cast iron covers and ventilators, 4 cents, all delivered Regina. Cement was $2.85 per barrel; steel, ½ in. and ¾ in. bars, 2.44 cents per lb.; 1 in. 2.80 cents; 1⅜ ins. 3.21 cents; 15-in. joists, 3.60 cents; 12-in. joists, 3.90 cents; standards, 3.90 cents, all deliverel f.o.b. Regina.

Placing of steel in the columns, average cost of labor was 26 cents per 100 lbs.; in floor, 12 cents; in walls, 30 cents.

Cost of labor, team and coal for mixing and placing concrete in column footings averaged $2; columns, $10; floor, 82 cents; walls, $1.10 per cubic yard.

Generally.—Tenders were invited for the construction of this reservoir, on the understanding that the city would supply all cement, gravel, steel and cast iron work, with the result that the lowest bid was $63,176. The engineer's estimate was $46,497, to which was added $6,974 for contractors' profit, making a total of $53,471. The offers were considered to be too high and it was decided to carry out the work by day labor, under the superintendence of Mr. Herbert Gibson. The total cost was about $88,000, of which the items which the city would supply under the contract absorbed about $58,000. The modifications in the design and specifications no doubt effected some reduction in the cost.

Mr. Theo. Brockman was resident engineer during the first season. Mr. L. A. Thornton, the city works commissioner, took an active part in the organization of the work, and Mr. J. McD. Patton, followed by his successor, Mr. J. Mackay, waterworks superintendent, attended to the matter of supply of materials. The reservoir was designed and supervised by the writer.

An important scheme has been put forward by the Egyptian Government for the Mahmoudieh Canal at Alexandria. It involves transforming the canal into a great fluvial harbor, seven miles in extent. At present the canal from the docks to Atfeh is under conflicting administrations. The importance of the canal to commerce and shipping is well borne out by statistics of vessels passing through it during 1910, when 6,512 lighters and sailing vessels and 165 steam tugs and steam barges passed down, and 6,507 and 179, respectively, up stream. These went through the tail locks of the canal at Alexandria, while for the Kafr Dawar lock 14,722 and 665 sailing and steam vessels, respectively, passed down and 13,323 and 680 up stream, and 19,713 boats passed through the Atfeh lock. The Government's scheme is to take away all control from the municipality and the other departments and transfer the canal to a single responsible body. From Hagar Nawatieh to the Mahmoudieh locks (seven miles) a fluvial harbor will be built along the banks, which will enormously improve the discharge of merchandise and facilitate the discharge of cotton. At present boats have been jammed for three weeks owing to the block of traffic and lack of control. Lewa Gedge Pasha has sounded the canal, and it is to be dredged soon and convenient landing stages constructed of concrete, each fitted with a crane capable of lifting four tons. The whole seven miles will not be dealt with at once, but the new fluvial harbor will first be made up to the Farkha Canal.

PIECE WORK SYSTEM APPLIED TO CITY FORCES.

MR. J. E. TUPPER, city engineer of Pomeroy, Wash., has an article in Municipal Engineering on the construction of municipal work by a new plan, some features of which, and the article describing them will be interesting to our municipal engineers, even although they, perhaps, cannot concur in all respects with the position taken by the author.

When the city of Pomeroy, Wash., was about to install its sewerage system the question of how it should be done, whether wholly by contract, partly by contract and partly by the city, or wholly by the city, was an important one and caused much discussion. We had no local contractors capable of handling the work and we were averse to letting the work to contractors from other places, even though there might be an apparent saving by doing so. The previous experience of the city in doing its work with city force had been so generally satisfactory that the council was strongly in favor of that method if some means could be devised of overcoming the one apparent defect in the system. While we had some men who would do as good work for the city as they would if working for a private individual, or even for themselves, a large number of the laboring men are inclined to take it easy when working for the public, and a by no means negligible element will "soldier" whenever and wherever possible. In all of the previous undertakings of the city the crews had been comparatively small, and it had been possible to eliminate the undesirable element, either by refusing them work when their traits were known, or by discharging them as soon as they began shirking.

In preparing for the installation of the sewers it was evident that a new factor entered the problem. The necessary force would be so much larger than any previously assembled by the city that we would need every available man, and would probably need to import some. Now, while the crew was small we could pick our men without causing much hard feeling, and even if a man was discharged for inefficiency, but little trouble was experienced, because his place was taken by another home man. When, however, it comes to replacing home labor with imported labor the matter becomes serious, and the offense would need to be flagrant to justify it.

It is well known to engineers and foremen that the efficiency of any crew is gauged very closely by the efficiency of the poorest man in the crew, and the example of one or two shirks will often have a disastrous effect on the discipline and efficiency of even the best of crews.

The problem that confronted us was that of employing all available home men, importing as few laborers as possible, and doing this without reducing the efficiency of the force below that of a picked crew.

The nature of our work was such that the employment of machinery to any considerable extent was impractical. Our water supply system, if system it could be called, is such a maze of pipes, the location of which is unknown, that the employment of a trenching machine would result in such utter demoralization of the water supply that the expense of repairing breaks in private pipes or cutting out and replacing them would more than offset the reduced cost of trenching. The water mains had been placed without any survey or record of location. In one case where the sewer location presumably paralleled a water main for 2,600 feet at a distance from the main of three feet, we found the water main in our trench for nearly one-third of the distance, and it crossed our trench eight times.

We knew that these conditions existed, and had a very good idea of the obstacles we would be likely to meet. The conditions were not favorable for letting a straight-out contract for the trenching. It was certain that a large portion of the trenches must be dug by hand, and the amount that might possibly be better handled by a machine was too small to warrant bringing in a machine for the purpose. In the purchase of supplies the city was in position to secure fully as advantageous terms as any contractor could possibly get. The manner in which the pipe was laid and the back-fill tamped was of such paramount importance that we felt that the city should retain full control over the workmen who were doing this work. This could only be secured by having the work done by city forces.

After a full canvass of the situation in all of its phases the council decided to have the work done entirely by city forces. It was then up to the engineering department to devise some scheme for overcoming, in part at least, the most objectionable features of that system.

The writer suggested the piecework method of payment, and advised its application to as much of the work as could be done without too much trouble. Many doubts were expressed as to the feasibility of the plan, and the council seriously objected to allowing it to be applied to the pipe-laying because of the danger of the work being slighted.

After considerable discussion the council agreed to allow a test of the method to be made on the trenches only, all other work to be done by day labor. The trenches could be handled by the new method more easily than any other part of the work, and if there should be any tendency to slight the work on the part of any of the workmen it could be easily corrected without endangering the perfection of the sewer. The accounting was a simple matter. Cross timbers for alignment and level purposes were set by the engineering force at 25-foot intervals, thus dividing the trenches into convenient one-man sections. The records of the engineer's office gave the amount of excavation in each 25-foot section, and a single setting of the slide rule gave the compensation. There was a little additional bookkeeping involved, but no complications. A simple method of numbering the sections was adopted, by means of which each man could keep track of the sections excavated by him, and the location of each section could be quickly determined if its number was given. The engineer's record was kept in the ordinary field book, and as there would be no embankment that column was used for entering the compensation for that section computed on the earth excavation basis. As the timekeeper's reports came in, the name of the one excavating a section was entered under the head of "Remarks." In this way complications were rendered impossible and omissions were quickly run down.

As fast as the classifications reports came in from the engineers they were entered on the same book and the proper compensation correction for each section was entered in red ink. The credits shown on the field book were transferred to a single-entry ledger and payments made bi-weekly. We found that though the accounting took a little more time than the day wage system, it was negligible as compared with the advantages that were found to accrue from the new plan.

We had very little data from which to determine what would be a fair scale of prices. Taking what we had, because of it being something of an experiment at best, preferring to be liberal in our prices, we fixed the following scale: Excavation per cubic yard: Earth 15 cents, hardpan 30 cents, loose rock 60 cents. What solid rock we encountered was excavated by day labor men. The amount was small. As it was a little doubtful whether we would be able to secure as many men as we needed for the trenches at these prices, it was announced that if, after a two weeks' trial it was found that the prices were too low to enable the average man to earn ordinary wages, then we would either increase the schedule or return to day wages. With this encouragement enough men were secured to begin operations, and before the first week ended the success of the plan was assured. In fact, the trenchers were able to earn such wages that we were forced to increase our day wage scale in order to hold the men we wanted on the other work. While at first glance this might seem to be a disadvantage, in actual practice it proved to be the reverse.

It gave us the advantage of a sliding scale in place of an arbitrary one. Our minimum wage was $2.50 per eight-hour day. When a day wage man wanted to go in the trenches we had this option. If he was a poor or indifferent worker we would let him go, but if he was a desirable man we would increase his wages to a price that would hold him. If a man was found shirking or slighting his work we would manage to get him in a position where there would be nothing for him to do just then except to go ahead into the trenches, and once in the trench, he would not get on the day wage force again. On the other hand, if there was a man in the trench that we wanted on the day force we could usually secure him. In this way we were able to keep a force of select men, and there was practically no complaint of unfairness or favoritism.

There was much less of this than we expected, and, as they had but two grounds for complaint, yardage and classification, it was very easy to get rid of them. As a whole, the trench men were perfectly satisfied with the deal we gave them. We were very liberal in our classification, were not unnecessarily insistent on having the sides of the trenches trimmed to line, and when unusual difficulties or obstructions were encountered we either gave them extra pay or took over the section to be excavated by the day men. There were a certain number of the trench men who were kept there throughout the entire job. They were worth more there than anywhere else, both to themselves and the city. These men averaged $4.00 a day or more, one of them averaging $5.00. Their example was a stimulus to the entire trenching force. To watch the twenty or more men we had in the trenches for one day was one of the best object lessons on the relative efficiency of common laborers that I ever received. The incentive for efficient work was the same in each individual case. Each man knew that he would get full pay for what he accomplished, and no more. And yet the variation in the amount of the day's work was astonishing. It ranged from 16 to 35 yards of earth in an eight-hour day.

So great a variation must have some reason for its existence. As a rule, the ordinary foreman would not see enough difference to warrant a remark. To all appearances the men were working equally hard, and on the whole with equal diligence. Jones was a husky specimen of the laboring class, above the average in intelligence, especially shrewd and quick to catch on to short cuts and ways of saving his muscle at the expense of his brains. As a day-wage man he was the most persistent, unscrupulous and shrewd hand at "soldiering" that we had in the city. Working in the trenches by the yard, he drew down the largest pay checks of any man in the crew. He worked no harder than other men, but he knew how to make every move count, and, having no incentive for shirking, he kept his shovel in motion. He spent no time talking, looking around or loafing on the job. He

simply worked intelligently and persistently. The only chance to get ahead of the job was in the width of the trench, and these he dug as narrow as he dared. Sometimes he overstepped the limit and had to be called back to trim up, and he always did so cheerfully. He was never a "kicker."

Brown was another husky man. He was the equal of Jones in intelligence, but was less shrewd and more conscientious. He knew how to take advantage of his work, and could, for a short time, move dirt as rapidly as Jones could. The trouble with him was that he could not keep from talking, and could not talk and work. As a result, he spent but little more than half of his time in actual work, and though his pay check was up to the average, it was not what it ought to have been if he had only been reasonably diligent.

Davis was probably the best man of the three, physically and intellectually, but he was inherently so abominably lazy that he had never learned to work and was the despair of all foremen. He was kept in the trenches because he was not worth his salt in any other place and we did not want to actually discharge him. Placed where he had to earn his money, he did make an effort to hold his own, but though to all appearances he worked harder than either of the other men, he was barely able to make minimum day wages. He had plenty of strength, but did not know how to apply it. He failed because he had no system, failed to give any thought to the way he was trying to do the work, and was actually too lazy to use his brain to save his muscle. The same condition existed all along the line.

The Results of the Experiment.—The first marked advantage was that noted above, the opportunity that it gave us of weeding out the undesirable workers from the day-wage forces. The next and undoubtedly most important feature was the marked esprit-du-corps that grew up rapidly in the entire force. It started with the emulation among the trenchers and extended rapidly back through the day-wage men. The knowledge that every man would be expected to "make good" or lose his position was very soon disseminated throughout the force, together with the further certainty that each man would be paid according to what he was able to accomplish, whether he worked in the trenches or by day wage, at least so far as we were able to adjust the compensation under the system pursued. This spirit was so marked and the stimulation that it exerted over the entire force was so great that we would have been decided gainers financially even if the actual cost of the trenching had been more than it could have been contracted for. As a matter of fact, the cost was about four cents per yard below what we could have hoped to get it done by contract.

Where Piecework Payment is Practicable.—The unanimous verdict was that the experiment had proved an unqualified success, and the only regret was that we had not applied it farther than we did. It is very evident that it would be impracticable to attempt to put all of the city forces on the piecework basis, but it was the consensus of opinion that, so far as it was practicable to apply the system, it should be done. The city will on the whole get better work for this reason. The foreman or inspector is anxious to keep the unit cost down, and will frequently pass up shabby work rather than put the city to the expense of making it good when it has been done by day-wage men, but if it was done by piecework he would insist on having it made good before certifying the job up for payment. Then the men themselves are much better satisfied. They get pay for what they accomplish. If there are any strikes under such a system it is because the employer is trying to squeeze out that last penny. The unit price should be such that the poorest man in the crew could make average wages. The cost would then be little, if any, more than under the day-wage plan, while the men would be getting so much more that there would be no incentive for a strike, and the indirect gains to the employer would be ample to warrant the adoption of the plan.

METHODS OF HANDLING LIGHT EARTHWORK.

MR. H. C. LANDON, general manager of the Watauga and Yadkin River Railroad Company, in North Carolina, writing in the *Railway Age Gazette*, makes some very useful observations from experience gained in the moving of 330,000 cu. yds. of earth, on 14 miles of his company's line. He includes details bearing upon labor employed and cost of work that should be of value. The article, as it appears, is as follows:—

The equipment necessary to grade a railroad depends largely on its location with reference to connections with other roads, the characteristics of the profile and the yardage to be moved in the several cuts to make the fills. In the construction of the Watauga and Yadkin River Railroad, which is building from North Wilkesboro, N.C., westward toward Boone, the fills are generally light and the cuts are not very heavy, although there are some comparatively heavy side hill cuts with a large percentage of rock. The difficulty of moving steam shovels far into this country on account of the very poor roads and lack of bridges, eliminate them from consideration, and a study of the profile therefore determined that the greater portion of the earth and rock must be moved with drag scrapers, wheel scrapers and explosives.

Scrapers.—The drag scraper can be used for very short hauls, but it was soon found that wheelers should be used for hauls over 60 ft., except in special locations where it is desired to move earth quickly and the distance is very short. A motion study developed the fact that with drag scrapers the speed of the mules was not over 7,200 ft. per hour, with a haul of 150 ft. on account of the frequent stopping to load the drag, and with a scraper force of six teams and a plow team the cost was about $0.20 per cu. yd. When the distance was not greater than 50 to 70 ft. the cost of moving by drag scrapers was not more than $0.12 per cu. yd., and earth has been moved for about $0.11 per cu. yd., where little or no plowing was necessary. Observations made on 110 ft. hauls with drag scrapers indicated that under the best conditions 25½ trips were made per hour, giving a speed of 5,600 ft. per hour and approximately 25 yds. per team at a cost of $0.17 per cu. yd.

As a general proposition the drag scraper is expensive in moving earth and should not be considered. A few drags on the job, however, are valuable and convenient, especially for special purposes. In one instance it was questionable whether it would not be cheaper to make a fill with drag scrapers from a borrow pit alongside and waste earth from a cut approximately 600 ft. away. It developed that the cost to make the fill from the adjoining borrow pit was approximately $0.12 per cu. yd., while the cost of hauling the material from the cut with wheelers was only $0.14 per cu. yd. To waste the cut and make the fill with drag scrapers would have cost not less than $0.24 per yd.

Observations of the wheeler forces showed that the speed of the wheelers with the above haul was about 133 ft. per min., or about 1.5 miles per hour. An average of 300 yds. per day was handled with this wheeler force of one foreman, nine wheelers, one plowman, one loader, one dumper, one snatch team and one four-mule plow team, at a total cost of approximately $34 per day. This force, therefore, handled 300 cu. yds. at an approximate cost of $0.146 per yd., and the amount handled could probably be increased if some system of premiums were devised. The low cost per team is due to the fact that the company owns its own teams and that $3 per day is considered a high price for teams in the locality in which this road is being constructed.

Careful observation showed that with a haul of 300 ft., nine wheelers averaged 55 cu. yd. per day per wheeler at a cost per cu. yd. very little above $0.09. The material handled was river bottom material, which is easily plowed and not difficult to handle, or a side hill cut with a subsoil of a reddish clay not much more expensive to handle than river bottom soil. Thirteen wheelers with 800 ft. average haul handled 300 cu. yds. per day at a cost of $0.168 per cu. yd. With this haul it was cheaper to move the material out of the cut into a fill that attempt to make the fill from the side ditch alongside, provided it was necessary to waste the material in the cut.

The advantage of the wheeler is in its capacity. The drag scraper requires from eight to ten loads per yd., while a No. 2½ wheeler requires but little more than two loads. The average speed of the teams operating wheelers in general is about 1.5 to 1.9 miles per hour, and on long hauls where there is no delay in loading, teams will make an average speed of 2.3 miles. On December 31, 1912, observation was made of two wheeler forces, both handling stiff red clay on side hill work. In the first instance, the force consisting of one plow team, one snatch team and six wheelers, with an average haul of 415 ft., made four trips in exactly 20 min., travelling through some mud, or at a speed of 9,960 ft., or 1.9 miles per hour. The second wheeler force using nine wheelers, one plow team, one snatch team and with an average haul of 510 ft., made seven trips in 48 min., equal to 1.7 miles per hour. Each wheeler in the first force should, therefore, make approximately 12 trips per hour, or 120 trips per day and handle nearly 60 yds. of material. In checking the record of one-half day this was approximately what the teams were doing. The longer haul should have been made with greater speed per hour, but the condition of the ground over which the material was deposited made the movement somewhat slower than that of the other force. Even at this rate the labor cost per cubic yard would not very much exceed $0.10, and under these conditions each team would handle 89 loads per day, or nearly 44 yds. per team.

With good teams and careful arrangement of the work the cost of wheeler work, even with hauls of 600 or 800 ft., can be kept down to a moderate price, provided the material is earth and can be plowed without much difficulty. The handling of material with drag scrapers where there is much rock is not very successful, although cuts have been handled successfully where material had to be blasted.

Dump Cars.—Four small dump cars of 2 yds. capacity were used in the work. As it was difficult to get light steel rails, wooden rails made of 4-in. x 4-in. timbers were provided. These cars were used to move rock at a tunnel approach and in short cuts where most of the material was rock, which was required for the fills. The cars were loaded by hand and the hauls averaged about 250 ft. The cost per cubic yard with this haul did not exceed $0.17. Where the haul was over 100 ft. the average gang loading cars, including drillers, was 14 men. This force would move about 150 yds., largely rock, at a cost of about $25.

Dump cars for short hauls, of approximately 100 cu. ft. capacity, have proved very convenient for disposing of earth, where the haul was short and speed was not a requirement. The average gang employed loading carts was about ten men, and such a gang would handle 75 cu. yds. per day at a cost of approximately $19.50.

Powder and Explosives.—The location of the line being largely on side hills and in places where there was little or no danger in moving earth and rock with powder, it was decided to move a large portion of the side hill cuts by this means. Up to this date approximately 5,000 kegs of powder have been used, moving approximately 50,000 cu. yds. At first it was difficult to get the foremen to use the powder, but we finally succeeded in arranging the work so that the entire section lying between the small runs on the hillside was drilled with the proper number of holes; about on the centre line, if in soft rock, or near the ditch line, if in hard rock, and from 10 to 17 ft. apart, depending upon the depth of the cut. These side hill sections were usually from 300 to 400 ft. in length, requiring from 30 to 40 holes. A No. 3 blasting machine was ordinarily ample to handle the shots. The first order of powder was for only 400 kegs, which was used in small units, but to very good advantage, moving approximately one yard of rock to every 2 lbs. of powder used.

One 80-ft. cut offered a serious problem. After a study of the situation it was decided that it might be possible to construct powder tunnels and blow off the top of the hill, thereby making an open cut. The line crossed a narrow ridge on a sharp skew which would enable the powder if properly used to throw the material away from the line. The first attempt was made at the west end of the cut, tunnels being driven at right angles to the line to the ditch line, and then both ways on the ditch line approximately 25 ft. above grade. It was supposed that a thorough study had been made of the material, which was generally stiff, hard clay or rotten rock, but it developed that a very hard rock existed on the west end of the tunnel parallel to the line. This disturbed the calculations somewhat. Only 400 kegs of powder were used to make the blast, the powder being placed in paper flour sacks and loaded in a compact manner in the tunnel, approximately filling it, the tunnel being 4 ft. wide and 5½ ft. high. Electric exploders attached to five or six sticks of dynamite were placed in the tunnel at intervals of approximately 25 ft. on the connecting wire lines. The end of the tunnel was tamped very thoroughly. The explosion which followed moved a large amount of earth, and earth which would have had to be removed finally to get to the mouth of a tunnel, which is now being constructed. However, while about 8,000 cu. yds. of material was moved the blast did not do the work expected. The hard rock west of the main tunnel proved of such great resistance that scarcely any material was moved at the summit of the cut, indicating that not enough powder had been used at any point in the tunnel and that the powder tunnels were not properly loaded to move the earth above and beyond the tunnels. The tunnel at the east end was then more carefully planned. Small tunnels were extended out 25 ft. at right angles to the main bore so as to reach approximately the north ditch line. The powder tunnel in-

dicated that most of the material was rotten granite rock, not very difficult to move. It was estimated that about 15,000 yds. were to be moved and it was decided to use only 20,000 lbs. of powder. This powder was loaded in the tunnel in paper sacks as in the previous case. The exploders and the line were placed in the tunnel at approximately the same intervals as in the first instance and were all carefully tested. The total length of this tunnel was 245 ft., the powder filling all but 30 ft. of it. This blast moved approximately 14,000 yds. of earth.

Several other large blasts have been successfully made along the route in side hill cuts on different sections of the line, moving almost one-half yard of material for every pound of powder used. In one cut, estimated at 8,000 yds., 95 per cent. of which was solid rock, 33 holes were driven in two rows, the upper row being approximately 20 ft. deep and extending 2 ft. below grade, while the lower holes were 16 ft. deep, extending 6 ft. below grade. The holes were expanded twice; first by using five or six sticks of dynamite, and then by using 25 or 30 sticks. This material was all rock, and the second expansion of the holes was necessary, although it is believed that one expansion of the holes, using 10 or 12 sticks of dynamite would have given better results, as the second expansion tended to fill the holes rather than open them up to sufficient size. An average of 11 kegs of powder was used in expanding the upper holes and 13 in the lower holes. The results of this blast were very satisfactory, 378 kegs of powder being used, moving fully 7,000 cu. yds. of rock. A No. 3 push down battery was used in this explosion, although this was overloading the battery slightly.

In all the smaller shots that are being made, the foremen are instructed to use powder judiciously, and they are getting good results with a minimum amount of powder. The holes made on the centre line to a point about 2 ft. below the grade line and are spaced a distance apart equal to the depth of the holes. It is found that the holes drilled on the centre line and to this depth below the grade will ordinarily pull down the grade about the amount desired, and will not move the earth too far back of the slope line where soft rock is handled. In some locations where we have encountered a very hard granite the upper holes are placed on the ditch line. Steam drills are used with hard rock, while a large percentage of the other holes are put down by hand and churn drills.

The total yardage in grading 14 miles of the road is 330,000 cu. yds., 20 per cent. of which is rock. This was moved with an average of 72 teams, 200 men, 150,000 lbs. of powder and ten tons of dynamite in less than six months. The average labor cost of moving earth was $0.15, and rock, $0.36. The wages paid for common labor were $1.40 per day, drillers $1.60, and hired teams $3 per day.

DRYING PEAT FOR GAS PRODUCERS.

A recently issued French patent describes a process whereby disintegrated peat is pressed into a thin cake between two endless filtering bands which pass between perforated metal supporting plates or over a metal pulley and are suitably tensioned. The moisture in the peat is thus reduced 60 to 80 per cent. The peat is then further dried by exposure to hot air or to the heat of the sun. A suitable hot-air dryer comprises a chamber through which large quantities of hot air are blown in the upward direction, whilst the peat cake, in small pieces, travels from the top downwards in a zig-zag path on a series of endless bands.

SHOP TRANSPORTATION SYSTEMS.

By Henry Grattan Tyrrell.
Consulting Engineer, Evanston, Ill.

ALMOST all industrial works are now provided with shop cranes for lifting heavy weights, but many are lacking in facilities for the economic handling of small parts. It is still a common sight to see slow-moving cranes of large capacity lifting pieces that are just too heavy for loading on trucks by hand.

The principle must be maintained that materials in process of construction should pass through the works in the most direct course, with the fewest side detours and no backward movements. The production from a shop may be compared to the discharge of water through a pipe. In the latter case, the volume of discharge depends on two factors: (1) the size of the pipe, and (2) the rate at which the water moves. The size of the pipe corresponds to the proportions of the buildings and the number of employees and machines, and the velocity to the rate at which the men can perform their work. With the plant limitations fixed in reference to its equipment, the rate of performing work is, perhaps, the chief factor in production. Much has been written in reference to human efficiency, and the best methods of securing a full day's service from the workmen, and too little about assisting him with convenient appliances. A man's producing power in a factory is limited by his tools, and the lifting and transporting systems are among the most important. As every hour of a workman's time is a definite expense, he should have enough assistance that no time need be wasted.

The subject of "Shop Cranes" is so large that little or no attention can be given to it here, for it is thoroughly covered in several comprehensive volumes. The other transportation facilities include: (1) locomotives, (2) hand-cars, trucks and carts, (3) trolleys on mono-rails, (4) conveyers, moving platforms, transfer tables, etc.

At a first glance it might seem best to install a single lifting appliance large enough to meet the maximum requirements of size and weight. But further thought will show that principle to be erroneous, the economic arrangement being to handle large pieces with heavy machines and smaller pieces with lighter ones. The principle corresponds with the well-known one on railroads, that smaller cars are preferable to larger ones for small loads and frequent stops. Neither is it economical to invest so much money in handling appliances, that the whole needs of the plant in this direction can be served in a small portion of the day and then remain idle, for a large proportion of capital invested is then unproductive for much of the time. Between a lack and a surplus of transportation system there is a mean where only enough money is expended to just suit the regular needs.

Trolley Systems.—Overhead trolleys carry their loads in suspension from an elevated track, and in this way differ from floor transportation. They are appropriate when a floor is covered with litter where trucks would be obstructed in their movements. They are cheaper than travelling cranes, and most efficient for continuous service. In crossing a stream between buildings the trolley may run on a wire rope. They are suitable for handling weights up to a maximum of five or six tons, though they have occasionally been used up to ten tons. Out of doors they can hang either from a light trestle or from brackets on the side of buildings, and they can turn corners of small radius. For continuous service, the loaded trolley on a down grade will haul back the empty one, and for passing from one story to another the trolleys move on an incline, though for intermittent ser-

vice they can be taken on an elevator. They are suitable when only a simple arrangement of trolley tracks are needed, and not when the tracks would be numerous or complicated. They have the advantage of turning sharp corners easily, and in winter are free from obstruction from snow and ice when yard tracks on the ground would be blocked up. For conveying small parts, they may be supplied with a metal basket carrier, similar to those commonly used in stores, and for heavy loads of a ton or more they should have a motor. In some cases it will be economy to use a "man trolley," with an operator's cage and a man aboard for controlling all movements, as in some of the modern coal and ore-handling machines, where the trolleys travel at the rate of 1,000 feet per minute.

The best form of track is that of curved metal in inverted U form, with treads for double wheels, with the weight suspended between them. It is similar to a common form of track used for large rolling doors. Flat bars on edge are also used with a single line of wheels, and rolled steel beams with double wheels running on the lower flange. They can have switches and crossovers, but, after all, trolley systems serve only the floor directly beneath them.

Conveyer Systems.—Shop conveyers are of many kinds, including those of chain and belts, with fingers or boxes attached for carrying packages. Plain belts, held in a grooved position by side rollers, are good for certain purposes, and are often preferable to those with baskets. Table conveyers, or moving platforms, are used for carrying boxes or lumber, and circular conveyers are often convenient in foundries for sand and moulds. Multi-story shops should have elevators or moving stairs, especially where women are employed, for the energy wasted in stair-climbing could better be spent in useful work. Electric elevators with automatic floor signals, which need no operator, but which stop at the floor indicated by the button which the occupant presses, are now a favorite for workshops, but should be often and carefully inspected.

Where the floor is clear enough to permit the movement of floor trucks, these are often very convenient, as they can be shoved about anywhere. For cement or granite floors, they should have a slightly rounded tire, preferably covered with hard rubber.

Pneumatic tubes, like those in department stores, may be installed for the transfer of mail or small goods, and speaking-tubes are convenient between adjoining floors or rooms. A private telephone system connecting all departments is a great economy, and it should have branches wherever time can be saved thereby.

Yards and Tracks.—The arrangement of the yards includes the driveways, pavements, tracks, switches, yard-cranes, scales, car and locomotive sheds, watchhouses, fencing, etc. Brick pavement around works is easy to walk on and gives horses a good foothold, though preserved wood blocks are often preferred.

The track arrangement will require careful study, and the best plan will depend on the plant. A small manufactory with only very light products can, perhaps, be well enough served by a stub-end track or spur, while a works where many cars are handled must have a better system. A loop arrangement may then be the best, on which cars can move continuously in one direction and avoid much switching. Yards should generally have a system of narrow service tracks, but a broad gauge for receiving, storing and shipping is of the first importance. None but very small plants can afford to be without a railroad connection, three or four cars per month being reason enough for installing at least a spur track. Large plants should, to avoid congestion, either have a loop system, as mentioned above, or a double connection to the main line, with enough track for storing the maximum number of cars. Unless material moves freely and without useless switching, there will be loss of time.

In choosing between circuits and stub-ends switches, the latter may be good enough, though continuous track is better. The economic arrangement of yards is more difficult to plan in an old plant than a new one, where space is unlimited and unobstructed. Parallel tracks can be arranged in the form of "ladders," with switches, on which cars can be sorted. Wide-gauge curves should have a radius of not less than 235 feet, and the cost may be roughly estimated at $1.50 to $2 per lineal foot.

Narrow-gauge tracks should usually connect all buildings and yards, and they should be freely used about the plant wherever goods are carried. They are, in fact, a necessary supplement to the broad-gauge lines, which cannot be generally used because of the long radius required at the turns. Double lines should not be closer together than about six feet on centres, and if turntables are used at the junctions, their base should be down below the frost line. The gauge of these narrow tracks may be anywhere from 15 inches up to the standard width of 4 feet 8½ inches, though 30 inches is about the best. The minimum radius for curves is 12 feet for 21-inch gauge, and 40 feet for 30-inch gauge. Rails weighing 40 pound per yard are heavy enough for ties 24 inches apart, though in some places I have prescribed lighter rails. Their tops should never stand above the shop floors, and wheel flanges on the trucks should not be flat, but slightly tapered as on steam railroad cars.

Yard Motors and Hoists.—Yard motors include locomotives, propelled either by steam, electricity or compressed air. Where electric power is available, the electric locomotive is usually the cheapest, cleanest and most convenient, but the steam railroads often object to electric locomotives using their tracks. Where much inflammable material is piled about, such as in lumber yards, a steam engine is dangerous, and electric or compressed air motors are then preferred, though the latter requires the installation of expensive compressors especially for this purpose. When tracks enter buildings, steam engines are not desirable because of their smoke and gas.

Where the overhead trolley wires would interfere with cranes or other appliances, electric locomotives can have a connection through a continuous floor slot, or when entering a building, the trolley wire may be made to uncoil in advance of the car and furnish it with power, and coil up again as the car is withdrawn. A combination of electric motor car and derrick is a very convenient yard machine.

Yard cranes covering the whole storage and loading space are economical in many places, and for heavy goods gantry cranes need no obstructing ways, and in this respect are desirable. They may be of either the bridge or cantilever type, the load capacity in the latter case being limited by the resistance to overturning on the central track. In many large works, such as steel plants, material in course of manufacture is never touched by hand, all operations being mechanical from receiving the raw material to shipping the finished product. Shop cranes may be arranged to run outside of the buildings and connect with the yard system.

The rule generally in installing shop transportation systems is to use mechanical appliances wherever the saving of time and labor would more than pay the interest on the money invested in such extra equipment.

CANADIAN PACIFIC RAILWAY BARGE FOR NELSON, B.C.

The car transfer barge which is being built by the Polson Iron Works, Limited, Toronto, for the Canadian Pacific Railway will be used for transferring cars on the Kootenay Lakes. Its length over all is 224 feet, beam 42 feet 6 inches, and 8 feet in depth. The accompanying figure shows general plan, longitudinal bulkhead and bracing.

The frames for the bottom of the barge are 7 x 3½ x 3½ x ½" channels. The sides are 5 x 3 x ⅜" angles, and brackets 18 x 18 x ⅜", and to the side framing at bilge by 30 x 36 x ⅜" flange brackets.

The decking consists of ⅜-inch steel throughout. The shell plating is also to be ⅜ inch in thickness, while the sheer strake and keel plate will be of 7/16-inch steel.

The fender channel will be of 8-inch shipbuilding section. It will be provided with bosom plate of 7/16-inch steel, and flush riveted holes in the channel web for receiving the wooden fenders.

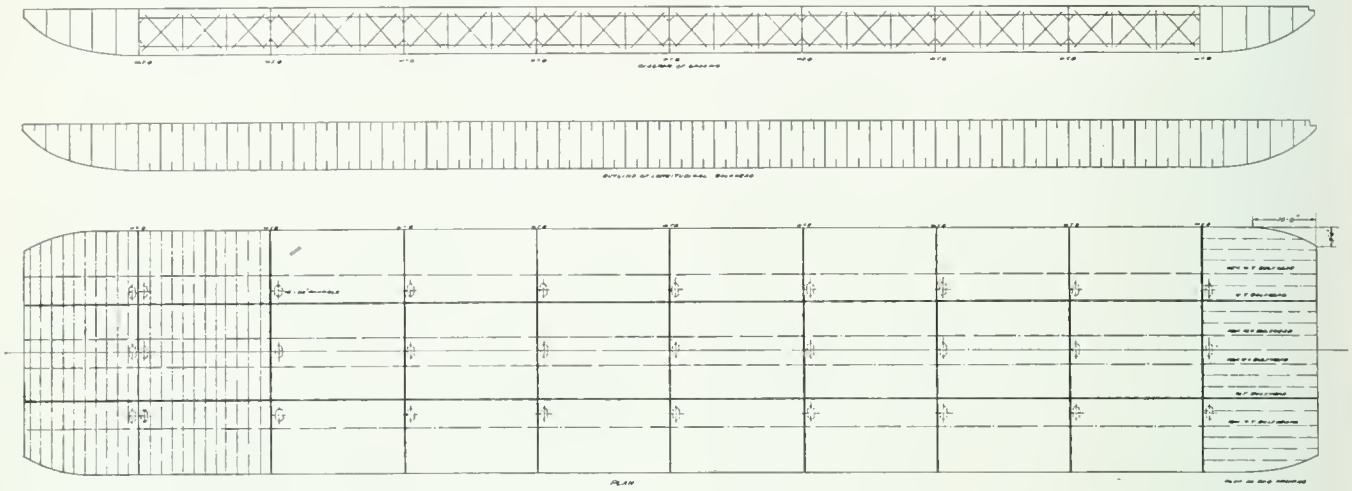

Fig. 1.—Plan and Sections of C.P.R. Transfer Barge.

scarphed for 18 inches to the channels. They are spaced 23 inches between end bulkheads. The frames in the fore and aft compartments are to be 5 x 3 x ⅜" between tracks and increased to 6 x 3½ x 7/16" in the way of the tracks, as shown on plan. It will be noticed that they are placed fore and aft instead of athwartships. The vertical side framing will also consist of 5 x 3 x ⅜" angles placed 24 inches apart. In the end compartment the framing will be bracketed at the end to the end bulkhead and deck with 5/16-inch bracket. The channel frames themselves are to be bracketed to the longitudinal bulkhead by

The barge will have nine transverse bulkheads of ¼-inch plate and six longitudinal bulkheads, each 5/16 inch in thickness. They will be extra heavily stiffened and braced with plates, channels and angles.

The barge when completed will be capable of handling fifteen loaded cars at a time. It will be provided with three tracks upon deck for this accommodation.

The hull is being erected at the contractor's yard in Toronto. After completion it will be taken down, shipped to Nelson, B.C., and there re-erected and riveted. It is expected that the delivery will be made this fall.

CEMENT PRODUCTION FROM RAW MATERIALS.

Covering a period of fifteen years, the following table shows the United States production of Portland cement in barrels, and the percentage of total output, for each type of raw material used in its manufacture, as prepared for the United States Geological Survey report on the United States mineral resources for 1912:—

Year.	Cement rock and pure limestone.		Limestone and clay or shale.		Marl and clay.		Blast-furnace slag and limestone.	
	Quantity.	Percentage.	Quantity.	Percentage.	Quantity.	Percentage	Quantity.	Percentage.
1898	2,764,694	74.9	365,408	9.9	562,092	15.2	.....	....
1899	4,010,132	70.9	546,200	9.7	1,095,934	19.4	.....	....
1900	5,960,739	70.3	1,034,041	12.2	1,454,797	17.1	32,443	0.4
1901	8,503,500	66.9	2,042,200	16.1	2,001,200	15.7	164,316	1.3
1902	10,953,178	63.6	3,738,303	21.7	2,220,453	12.9	318,710	1.8
1903	12,493,694	55.9	6,333,403	28.3	3,052,946	13.7	462,930	2.1

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, RAILROAD, MINING, MUNICIPAL HYDRAULIC, HIGHWAY AND CONSULTING ENGINEERS, SURVEYORS, WATERWORKS SUPERINTENDENTS AND ENGINEERING-CONTRACTORS.

Present Terms of Subscription, payable in advance
Postpaid to any address in the Postal Union:

One Year	Six Months	Three Months
$3.00 (12s.)	$1.75 (7s.)	$1.00 (4s.)

Copies Antedating This Issue by More Than One Month, 25 Cents Each.
Copies Antedating This Issue by More Than Six Months, 50 Cents Each.
ADVERTISING RATES ON APPLICATION.

JAMES J. SALMOND—Managing Director.
H. IRWIN, B.A.Sc., Editor.
A. E. JENNINGS, Advertising Manager.

HEAD OFFICE: 62 Church Street, and Court Street, Toronto, Ont. Telephone Main 7404, 7406 or 7405, branch exchange connecting all departments. Cable Address: "ENGINEER, Toronto."
Montreal Office: Rooms 617 and 628 Transportation Building, T. C. Allum, Editorial Representative. Phone Main 8436.
Winnipeg Office: Room 820, Union Bank Building. Phone M. 2914. G. W. Goodall, Western Manager.
Address all communications to the Company and not to individuals.
Everything affecting the editorial department should be directed to the Editor
The Canadian Engineer absorbed The Canadian Cement and Concrete Review in 1910

NOTICE TO ADVERTISERS:
Changes of advertisement copy should reach the Head Office two weeks before the date of publication, except in cases where proofs are to be submitted, for which the necessary extra time should be allowed.

NOTICE TO SUBSCRIBERS
When changing your mailing instructions be sure and give your old address in full as well as your new address.

MUNICIPAL ENGINEERING AND PUBLIC HEALTH.

At the convention of the Public Health Association in Regina, September 18th, 19th and 20th, the municipal engineers of Canada should have a strong representation, this branch of the profession being so closely associated with the health and development of communities. A special section has been arranged for engineers and architects and, in glancing over the list of papers to be read to this section, as appearing in last issue of *The Canadian Engineer*, the proceedings of the meeting will be carried on largely by and for the benefit of municipal engineers, which should be an incentive for them to attend. Papers to be read at other sections have a similar bearing upon the development work of municipalities, and, taken altogether, city and town engineers should turn out from quite a distance to this three-days' convention. The fact that some of them are not overburdened with development work at present is another argument in favor of their participation.

A suggestion has been made that those municipal engineers who attend this convention should hold an informal meeting at some convenient hour during its progress to discuss the feasibility of forming an organization primarily for municipal engineers. The idea of an association has certainly met with favor as many engineers have taken the time to write approving of the suggestions made in discussing the subject in our issue of July 10th. The opportunity, then, for exchanging views on the proposed organization will be welcomed, and should act as an added incentive for all to attend the Regina convention who possibly can. Although the gathering will not be sufficiently representative of Canadian municipal engineers to take any inaugural steps, the wisdom of collection of as many valuable suggestions as possible is apparent. Further, those who contemplate being present should signify this intention so as to add weight and make the proposed informal gathering a surety and a success.

ORGANIZATION AMONG MUNICIPAL ENGINEERS.

There seems to be unanimity of opinion among municipal engineers in Canada with regard to the lack of an official body as exists in other branches of engineering. Doubtless the municipal engineer, in his isolated position, needs an organization whereby his branch of the profession can stand alone. Municipal engineering is one of the younger branches of the profession, and like it, is an evolution of the artisan rather than of the early scientist. The engineer's work is becoming more scientific because of his relations and associations with the scientific world. These relations must become closer for the more direct application of science, through the municipal engineer, to the growth, health and general development of his municipality. He stands between a scientist and the work-a-day world with a keen appreciation of the value of the work of the one, and a ready understanding of the needs of the other; and his work consists in transforming the abstract results of the former into practical usefulness for the latter. His number is increasing and the intricacies associated with his professional duties will probably never subside. He is an indispensable member of the learned profession of civil engineering, whose growth during

the past decade would support claim to being a veritable profession of progress. As the larger portion of the immense material advancement of the world during the past century is due primarily and pre-eminently to its engineers, so has the tendency towards concentration of population, devolving from this advancement, necessitated the employment everywhere of the municipal engineer.

Again, the function of the municipal engineer appears to include everything but boundary. Civil engineering, as the term is understood generally, includes so many phases of useful construction that the ordinary citizen unfamiliar with the scope of municipal work, is disposed to consider this a very specialized branch. Yet it is scarcely practicable to draw a line between the profession, as a whole, and the duties of the municipal engineer. The former includes the design and construction of bridges, viaducts, wharves, piers, docks, canals, dams, irrigation works, retaining walls and other heavy masonry; tunnelling and extensive and difficult foundations; river improvements, harbors and waterways; water supply, sewerage, filtration and treatment of refuse; highway construction, surveying; railways (steam and electric); the general design and construction of power plants (steam, electric and hydraulic); of lighting plants (electric and gaseous); the heavier structural features of office and industrial buildings; the general problems of transportation, etc., etc. Has not the municipal engineer to be equipped with an up-to-date working knowledge of practically every item that one may classify under the heading of "Civil Engineering?"

Further the term "Civil Engineer," as upheld by the Canadian Society of Civil Engineers, the American Society of Civil Engineers and the Institution of Civil Engineers, covers thoroughly the field of the municipal engineer.

This brings us back to the opinion we expressed in July 10th issue of *The Canadian Engineer*, concerning the contiguity that would exist between the two if an association of municipal engineers were formed as a body separate from the Canadian Society of Civil Engineers. We believe that the existing Society will be more useful to a man engaged in municipal work, in establishing for him an association with engineers who, like himself, must keep in touch with the activities of all branches of engineering, and with the newer methods of scientific investigation, than would an institution, newly formed expressly for municipal engineers, many of whom are now members of the Canadian Society. The assertion is made with a belief that there are too many engineering and technical societies now existing in Canada, and also that among them there is none with a membership more difficult to build than that of the prospective organization.

A municipal engineers' section in the Canadian Society of Civil Engineers will give its members the best opportunity of forming for themselves a strong institution, coherent in itself and bearing directly upon all engineering applied to municipal development. It will have a strong organization behind it, and will continue to add strength to that organization as its membership increases.

Once formed, the establishment of sub-sections in the present branches of the Society throughout the Dominion and of other advantages, as for instance, a circulating library among these sections, equipped with the latest works on subjects allied to municipal engineering, will not be long in elevating that branch of the profession to what it should be, viz., one of the most inviting, from its present status, one of the least.

LEAGUE OF AMERICAN MUNICIPALITIES.

The seventeenth annual convention of the League of American Municipalities held recently in Winnipeg, brought forth a number of addresses and discussions on topics of more than usual importance. Mayor Deacon opened the convention with an address of welcome, responded to by Mr. John J. Ryder, superintendent of police, sanitation and public safety, Omaha, Neb., as president of the League.

Among the addresses made and topics discussed were the following:

C. J. Driscoll of the Bureau of Municipal Research, New York, formerly a police commissioner of that city, spoke of "Municipal Efficiency" with particular reference to the police departments. Mr. Driscoll's paper was a consistent argument for the expert in municipal affairs, mainly on the ground that municipal business is like any other business and requires long study and the application of scientific principles, if it is to reach the state of efficiency to which the people as ratepayers are entitled.

W. A. Larkin, street commissioner, Baltimore, read a paper on "Baltimore Street Cleaning and Garbage Removal." He mentioned particularly the good work of washing machines in keeping down the dust. In the discussion following, C. L. Willert said that Buffalo is one of the cleanest cities in the country.

Ossian Lang, Mt. Vernon, N.Y., president of the board of aldermen, read a paper on "Popular vs. Expert Government," in which he argued strongly for the popular representative form on the ground that the people themselves are nearly always right and that they have an unerring faculty for disposing of the man who has not proved his worth or efficiency. He described the professional expert as a man who thinks more of his job or his profession than of the interests of the community he may happen to be serving, and who is always ready to move along to any place that offers him more money.

In speaking on "Municipal Finance," W. Sanford ex-mayor of Winnipeg, reviewed briefly the history of municipal loans, noting that they were unknown two hundred years ago. Drawing from his own experience, Mr. Evans said that Winnipeg had found London to be the best market for the sale of its securities. The demand in London was for listed securities regularly dealt with in the stock market. Winnipeg is now issuing 1943-63 stock, that is, securities redeemable in that period. A large volume of securities was a benefit and a large list of holders as tending to make transfers possible without loss.

Charles L. Willert, councilman, Buffalo, N.Y., spoke on "Small Parks." He said that large parks chiefly benefited the owners of carriages and automobiles. Small parks attract the common people.

John B. Martin, election commissioner, Boston, Mass., spoke on "New Charter and Election Laws." The paper dealt principally with the new charter of the city of Boston and other local conditions.

Col. H. N. Ruttan, city engineer of Winnipeg, presented a paper on "Physical Construction of Cities," which brought out a lengthy discussion. "Municipal Light and Power" by J. W. Cockburn, controller, Winnipeg, and "Recent Development in Municipal Administration in Canada," by T. A. Hunter, K.C., corporation counsel, Winnipeg, were among the papers presented by Canadians at the convention.

QUANTITATIVE ESTIMATION OF GROUND WATERS FOR PUBLIC SUPPLIES.*

By Myron L. Fuller, Consulting Engineer, Boston, Mass.

THE development of water supplies from surface sources has long received the careful consideration of hundreds of engineers, including many of the most prominent in the country. The questions involved have been earnestly attacked, thoughtfully considered, carefully weighed, and painstakingly solved, not only for the large cities, but for the smaller municipalities, towns, and villages as well. The best thought of our best men has been freely given to the subject.

Ground-water supplies, on the other hand, with a few exceptions, have rarely received more than the passing attention of engineers. The problems, lying, as they do, outside the usual limits of the engineer's training and experience, have seldom been studied with anything like the same degree of thoroughness as the surface supplies. Too often, he has assumed, because they have been obscure to him, that the occurrence and movements of ground waters follow no definite laws, and that the securing of adequate supplies is, in most cases, a mere matter of luck.

In reality, the principles controlling the collection, absorption, storage, motions, and recovery of the waters within the ground are as definite as those governing upon the surface, and are worthy of the same serious consideration that has been given to the latter. If this is given them, their problems are equally open to solution, and the prediction of supplies will become a matter of comparative certainty rather than a mere conjecture.

Factors in Ground Water Estimates.—In any attempt to estimate available ground waters, a certain number of factors common to all localities must be carefully considered if the deductions are to be of value. These may be stated as follows: 1. Nature of water-bearing materials. 2. Storage capacities of water-bearing formations. 3. Availability of supply. 4. Area tributary to wells. 5. Velocity of underflow. 6. Rate of replenishment.

In the vast majority of cases the knowledge of the foregoing factors is practically confined to the first. In not more than one out of ten wells is there an adequate knowledge of storage capacity, rate of yield, or tributary area, while in hardly one in a thousand is the velocity or rate of replenishment seriously investigated. All the factors enumerated are susceptible of approximate determination and, when known, greatly restrict the range of errors of estimation.

Determination of Water-Bearing Materials.—The determination of the character of materials to be encountered in a well is not simple. In many instances the surface affords little indication of what lies beneath. The glacial deposits which overlie the rock in New England are highly variable in character and may range from loose sand to dense hardpan within an interval of a few feet. The depth of such deposits is subject to abrupt changes within short distances.

The character of the solid rock lying beneath the surface deposits is often even more difficult to determine, for although some formations are of nearly uniform character over wide areas, others change rapidly. In a large number of cases the changes occur beneath valleys where the rock is deeply buried.

The determination of the character of the rocks at considerable depths below the surface is seldom an impossible task; it may usually be made with a reasonable degree of accuracy. This work is properly that of the geologist, and the judgment of the engineer will ordinarily be of little value if the conditions are at all complicated. Too often he does not even know whether they are complicated or not.

An accurate determination of the character of the water-bearing materials is important, for upon it will depend the storage, the rate of yield, and the quality of the supply. The best information obtainable should be secured before drilling is begun.

Storage Capacities of Water-Bearing Formations.—The volume of the ground water depends directly upon the containing material, and if a quantitative estimate is to be made, the nature of the water-bearing bed must be accurately known, for upon it depends the character of the storage—whether in pores, in joints or fissures, in cleavage or schistosity plains, in solution passages or cavities, etc.

An intimate knowledge of the occurrence of ground water is again indispensable. Open cavities are encountered in rocks, but such openings are found only in limestones; in granites, sandstones and slates, there is no possibility of encountering such a passage. The supposed openings in the latter rocks, assumed to exist because of the sudden dropping of the tools while drilling, are simply soft streaks, consisting of clayey products of decomposition through which the drill penetrates at a single stroke. They are the result of the circulation of water within the rock, and will afford considerable water to wells. Water is found in the joints or fissures of granites, but the width of these is seldom more than 1/20 in. and is often less than 1/50 in., and few of them extend more than a few hundred feet, thus cutting off the possibility of a distant supply. These and other similar factors are of vital importance in the estimation of the yield of proposed wells.

Availability of Supply.—The availability of ground waters, or the quantity yielded to wells, has no relation to the storage capacity of the materials in which they occur. Often the formations containing the largest supplies will yield the least. In Table I. the first column indicates the volume of water actually contained in rocks and soils of various types, while the second shows the usual yield from the pores.

Table I. does not tell the whole story. For instance while clays will yield practically nothing to wells, they are of great value as feeders to underlying rocks, to which they slowly give up their water. In many instances the capacities of rock wells are probably doubled by the presence of their clay covering. Again, while the sandstones may show an ultimate yield of from 1 to 15 per cent. of their total supplies, the water often enters a well too slowly to be of value as a source of supply.

In fact, there are so many modifying conditions that the determination of the probable quantity of a proposed supply demands a thorough knowledge of ground waters and a careful study of local conditions.

Area Tributary to Wells.—The ultimate quantity to be derived from wells at a given point will be, other things being equal, proportional to the extent of the tributary area. It is not always a simple matter to determine the distance from which water will find its way

*From an address delivered March 12th, 1913, to the New England Waterworks Association, and appearing in the Journal of the association for June, 1913.

to a well, and a separate determination based on a careful examination, must be made at each locality. There are, however, certain general facts regarding the distances traversed by ground waters. Some of these are summarized in Table II.

The wide variations in the areas tributary to different sets of wells will be appreciated from an examination of Table II. The problems of source and tributary area are, naturally, geological in their nature and will require the services of a geologist for their solution. To one trained in this line they will ordinarily present few difficulties.

The Velocity of Underflow.—As in the case of a surface stream, the quantity of available ground water at a given point is determined by multiplying the cross-section of the moving water body by the velocity of its movement. This will give us the normal underflow, or, in other words, the maximum available supply; for, although it is possible to pump for a time from the reservoir (accumulated storage) within the ground, no more water can be obtained in the long run than is normally flowing within the limits of the area tributary to the wells.

Only in a very few cases has the velocity of underflow been determined in connection with the development of municipal supplies, although it is perfectly practicable where the water occurrs in unconsolidated material of reasonable uniformity and would undoubtedly prevent the waste of large sums in injudicious prospecting or unwarranted development.

TABLE I.

Porosities and Yield of Rocks and Unconsolidated Materials.

Material	Storage Capacity or Porosity Per Cent. of Volume	Normal Yield to Drilled Wells from Pores.* Per Cent. of Volume
Quartzites (average)	½	None
Granites (average)	1	None
Slate and shale (average) ...	4	None
Limestone and marbles (average	5	None
Sandstones	5 to 25	1 to 15
Gravel (mixed with sand)	20 to 30	10 to 20
Sand (medium to coarse)	30 to 40	10 to 25
Sand (fine)	30 to 40	5 to 20
Clay	40 to 70	None
Till or bowlder-clay	20 to 60	0 to 20

* The figures in this column do not include the yield from fissures, joints or cleavage planes Water remaining in rock is largely residual moisture held by capillarity.

The most successful process of measuring underflow is the Slichter method, described in the succeeding article. It can be applied by any mechanical or other engineer, but for the interpretation of results and more especially the determination of the extent of the tributary area, usually demands considerable geological knowledge and experience.

Rate of Replenishment.—An accurate determination of the rate of replenishment is of the first importance, for, no matter how great the storage and how large the tributary area, a large permanent supply will be obtainable only when the average absorption is at least equal to the quantity of water withdrawn.

In New England, the determination of the rate of replenishment is a comparatively easy matter, for we are here dealing with an area of abundant and well-distributed rainfall, relatively low evaporation and fairly simple absorptive conditions. In the western arid and semi-arid regions, on the other hand, the problems are more complex. There, the rainfall and evaporation are very irregular and it takes but little to disturb the balance and change a net gain to a net loss. When the loss by evaporation becomes greater than the rainfall, the replenishment can take place only by absorption of water from the streams, which often pour down more or less transient floods after heavy rainfalls. In such instances careful field observations, supplemented by laboratory tests to determine porosities and rates of percolation, are necessary to determine the rate of absorption and additions to the ground-water reservoir.

In the East, the problem requires a careful computation of the rainfall and an analysis of its seasonal distribution, together with a similar investigation of seasonal evaporation and plant transpiration and an accurate determination of the porosity, size of grain, rate of percolation, nature of vegetation and other minor factors regulating absorption.

TABLE II.

Distances Traversed by Ground Waters.

Material	Usual Distance of Source from Well	Ordinary Maximum Limit of Transmission in United States
Surface sands and gravels	Less than 1 mile	25 miles
Deep sands and gravels beneath clay or other confining layers	Several miles	100 to 200 miles
Sandstones near surface..	½ to 1 mile	5 to 10 miles
Deeper sandstones	Several miles	100 to 300 miles
Limestones near surface..	½ to 1 mile	10 to 20 miles
Deeper limestones	Several miles	100 to 200 miles
Slate or shale near surface	Less than 500 ft.	Rarely over 1 mile
Deeper slates or shales ..	Possibly several miles	Rarely over 10 miles
Granites	Less than 1,000 ft.	Rarely over 2 or 3 miles

NOTE —Some rocks are water-bearing at greater distances from the outcrop than is indicated in the table, but it seems probable that the water has been absorbed by capillarity from overlying materials rather than derived by transmission from remote catchment areas.

Limited Value of Test Wells and Pumping Tests.—Engineers have frequently remarked that the only way to tell whether or not one has a supply is to put down a test well and make a pumping test.

With this view the writer does not at all concur, for it may be readily shown that pumping tests come far from furnishing complete data as to the availability of permanent supplies. What a pumping test shows and what it does not show is concisely summarized in Table III.

That a knowledge of the materials at the well is insufficient is indicated by the fact that it is the average section for the whole area and not its character at a single point that determines both storage and movement of the ground water. This is not furnished by a single test well.

The pump may deliver during a test very large volumes of water, but, except where the supply is very limited and hence readily depleted, the test shows nothing as to the supply permanently available. Many wells tap groundwater reservoirs containing the accumulated supplies of long periods, but the fact that half a million gallons may be withdrawn daily for a few days is no indication that the permanent yield will be more than a small fraction of this amount.

When the water table stands high in the ground, the entrance of the water into a well is relatively rapid, but the rate of entrance declines as the water table becomes lowered. The extent to which the supply will be affected can be determined only by a study of the tributary area, velocity of underflow and rate of replenishment, no indications of which are afforded by pumping tests.

It is well known that in heavily pumped wells the quality of the ground-water supply often deteriorates with the passage of time, although possibly not for some months or years, but the nature and extent of the change is to be predicted from a study of the character of the materials and of the geological structure rather than from a necessarily brief pumping test.

TABLE III.—DATA FROM PUMPING TESTS.

Pumping tests show—

1. Character of material at well.
2. Presence or absence of water at time of test.
3. Rate of delivery when water is at maximum height.
4. Quality of water at start.

Pumping tests do not show—

1. Average character of material of tributary area.
2. Permanency of the supply.
3. Rate of delivery from depleted reservoir.
4. Quality of water after continued pumping.
5. Direction of movement of ground water.
6. Velocity of ground-water movement.
7. Source of water.
8. Extent of tributary area.
9. Rate of replenishment.

The direction of movement of the ground waters is of considerable moment in determining the liability of pollution by contaminating matter from the surface, or of the likelihood of the penetration of sea water or other mineralized waters from clays, shales, bog iron ores, peats, etc., but is not usually indicated by the pumping test.

Notwithstanding the limitations of the data furnished by pumping tests, they are of much value when their limitations are understood. They should, however, be regarded as adjuncts to ground-water investigations rather than as final in themselves.

WATER POWERS OF ICELAND.

The undeveloped water-power of Iceland is receiving attention this season. The Delbi Falls, 35 miles from the coast, have been acquired by an English concern, engaged in the manufacture of nitrogen products, and with 410,000 horsepower at its command, the company will move all its factories from Peru and Chile to Iceland. Big factories are to be built in the vicinity of the falls and a railroad constructed to the coast. The ownership of the falls was purchased for the sum of $60,000.

What is claimed to be the largest bascule bridge in the world has just been completed at Portland, Oregon. This new bridge, which is 4,800 feet long, crosses the Willamette River, connecting Broadway Street on the west side with Broadway on the east side. It provided an easy grade thoroughfare from the business district to the large residence district on the west side. This type of bridge allows practically unobstructed water traffic up and down the river. It was built by the city at a cost of about $1,300,000. The bridge is lighted at night by 250 5-light and 2-light fixtures, together with an outline scheme of 7,000 lamps spaced 18 inches apart. One hundred-watt tungstens are used in the pole fixtures and 32-candle power lamps on the outline system. Current is supplied to the lamps over more than 12 miles of wire in metal conduit.

TOWN PLANNING.*

By Christopher J. Yorath, A.M. Inst. C.E. (Eng.), City Commissioner, Saskatoon.

GREAT BRITAIN, by the passing of the Town Planning Act of 1909, took the first step towards the undoing of mistakes of centuries, and hopes by planning the future growth of existing and new cities to avoid the enormous expense occasioned through the lack of planning.

Until recent years it was thought that the checkboard system of planning was all that could be desired, but anyone who has studied the subject of town planning will realize at once that it is a failure, and has necessitated even in what are known as the New World cities large expenditure to rectify some of its many defects. How can a system be called a plan which does not take into consideration local characteristics, such as the undulation of the ground, a winding river, thickly-wooded spots and other amenities?

If Great Britain realizes the necessity of passing a Town Planning Act, surely such an Act would be of infinitely more use to Canada, which at present has only a population of about eight millions, or slightly more than that of London, while its area is 3½ million square miles compared to 112,000 square miles comprising Great Britain.

A careful study of what wise town planning, the liberal provision of attractive amenities can do, and has done, for some of the cities of Europe will convince the greatest anti-town planner of the wisdom of looking well ahead.

It invariably happens that town planning is not thought of or put into operation until a certain amount of development has taken place. In Great Britain this does not interfere to any great extent with the planning for the future, as the undeveloped land is not staked out into lots and held by numerous land-holders, but is usually in possession of a few; whereas in Canada, owing to the checkboard system and the selling of outlying plots far in advance of the time when the land is ripe for development, the proper planning of the future is rendered far more difficult, and probably in many cases the difficulties will be so great as likely to make a scheme impracticable without special legislation.

A city attractive by its beauty, by its artistic symmetry and design and convenience which it offers will gain a reputation and an individuality which not only its council and its landowners, but also its citizens, may be proud.

What, then, should be the aim of every city? and to answer that question we are at once thrown back upon the question of what should be the individuality by which the city should be marked and known. Bacon says in his "Essay of Gardens": "God Almighty first planted a garden. And, indeed, it is the purest of human pleasures, it is the greatest refreshment to the spirits of men, without which buildings and palaces are but gross handiwork." Surely, then, the aim should be the one implied by the term "Garden City," beautiful, well planted, and finely laid out, known and characterized by the charm and amenities which it can offer to those who seek a residence or dwelling removed from the turmoil, stress and discomforts of a manufacturing district.

The various systems of planning which have been adopted in the past are rectangular, radial and circumferential, and curvilineal, but the latest schemes for town

* Extracted from paper read at the Convention of the Union of Canadian Municipalities in Saskatoon, July 15th, 1913.

planning are generally a combination of all three, which allows for the best fulfilment of town planning ideals.

The problem, then, for the town planner is to consider his scheme in respect to:—

(a) The configuration and undulations of the site.
(b) Direction of main radial and circumferential avenues and boulevards.
(c) The layout and construction of avenues and boulevards.
(d) Open spaces, parks and recreation grounds.
(e) Tramways.
(f) Civic centre.
(g) Buildings—The space about the same; the limitation of the number of houses per acre, and the height and character of same.
(h) Restrictions of factories and works to special areas.

The Configuration and Undulations of the Town Site.—The beautiful sites which the Great Architect of the Universe has provided for many of our cities have been wantonly spoilt by the worst form of vandalism and the lack of a proper system of planning instead of providing a setting and vista by which the beauty of monumental and public buildings may be shown.

The first essential preparatory to the drawing up of a town planning scheme is to make a contour map of the site, with contours showing the rise or fall of the ground every five to ten feet. In addition, the map should show existing trees, places of historic or local interest, railways, existing public and industrial buildings, waterways, etc.

This map will enable the town planner to lay down the main avenues with the easiest possible grades; to preserve places of beauty; to establish the sites of the most important buildings so as to be in commanding positions; to design his storm and sanitary sewers so as to obtain the maximum amount of gravity flow, and to arrange his water supply in the most suitable zones to that the whole system of public utilities can be built up of units, which will ultimately become parts of a completed whole.

Direction of Main Radial and Circumferential Avenues and Boulevards.—In London and New York, and many other large cities, great inconvenience and expense is occasioned through not having the most direct means of transit between business, factory and residential districts, and proper connections between these centres and the different railway depots. Again, through the lack of circumferential avenues the traffic in the centre of the city becomes greatly congested.

It is imperative, therefore, in the planning of a city to exercise the greatest care and judgment in fixing the position and direction of main avenues. If possible, they should radiate from the centre towards the principal outlying districts north, south, east and west of the city, and be linked up with inner and outer circumferential avenues. By this means traffic desirous of crossing from one side of the city to the other can avoid the centre and more heavily trafficked streets, and in so doing prevent the congestion which so often occurs in the centre of old cities.

London is at present contemplating the construction of circumferential avenues in order to relieve the congestion which occurs in the centre.

In Vienna the Girdle Linie, or Outer Boulevard, is about eight miles in length; the total width between buildings is 248 feet. A separate strip of the road is set apart for the tramways and fast traffic; a continuous recreation ground or playing space is included in the scheme, well planted with trees to provide shade during the hot season.

Another circumferential avenue in Vienna is the Ring Street, or Hub, 178 feet wide. It has a central carriageway 41½ feet wide, which is principally used by fast and through traffic vehicles. On either side are the tramways on the electric conduit system. A riding track and promenade for foot passengers occupy the spaces between the trees, and slow and stopping vehicles find accommodation on the two outer roads.

These circumferential routes, which connect up the various parks and open spaces, are largely used by residents, motorists and cyclists as circular drives.

The Layout and Construction of Avenues and Boulevards.—It must be borne in mind that all objects in the street, utilitarian or otherwise, are things to be seen, part of an organic whole, each having their respective part and place.

Athens and Rome were each crowded with such objects, arranged for the most part in picturesque association. Although it will be impossible for young cities to expend much money, if any, upon beautification, beyond the planting of trees, a town planning scheme should allow for such improvements at some future date at a minimum of expense.

Long, straight avenues, with buildings of approximately the same height and no object to break the horizon, should be avoided. If natural scenic effect cannot be obtained, then provision should be made for some architectural feature to break the skyline. By careful planning it can generally be arranged to place a church, a public building, or artistically designed residence to break the monotony of long streets.

In Germany this branch of town planning is given careful consideration, and long avenues are usually broken by means of "squares," so that the line of sight will be met by a building, the architecture of which has been previously approved by the local authority.

In planning out the widths of main roads it is difficult to estimate what the future will demand, but in any case it will be better to err on the wide side rather than the narrow.

The various types of streets usually required in a city are:—

(a) Main business avenues, with provision for tramways and boulevards—width from 100 to 200 feet.
(b) Secondary business avenues, without provision for tramways—width from 80 feet to 150 feet.
(c) Semi-residential avenues, with provision for tramways, side and centre boulevards—width from 80 feet to 120 feet.
(d) Semi-residential avenues, without provision for tramways, but with side and centre boulevards—width from 80 feet to 100 feet.
(e) Residential avenues, without provision for tramways, but with side and centre boulevards—width from 60 feet to 80 feet.
(f) Secondary residential avenues, with carriageways to take local traffic only, with side boulevards and an established building line of 30 feet—width from 40 feet to 60 feet.

The main avenues should be laid out with 12-feet sidewalks, slow traffic carriageways next sidewalks, and boulevards on either side of a centre carriageway for fast traffic and tramways.

The secondary business avenues should have sidewalks of a minimum width of 10 feet, with a centre boulevard with wide grass margins, so that the actual paved carriageway can be widened as the business of the city extends.

In main and secondary business thoroughfares provision should be made for laying all sewer, water, electricity and other mains in underground conduits of sufficient size to allow of proper inspection at all times. The advantages of this method are:—

(1) The pipes being open to inspection at all times, leaks can be more easily located and repaired.

(2) The traffic is not inconvenienced by frequent openings for repairs.

(3) The enormous annual expense of opening trenches is saved.

(4) The surface of the carriageway, which soon becomes uneven if many trenches are made, retains an even contour.

The residential avenues can be so formed that the sidewalks have a boulevard on either side, which will provide space for pedestrians in the hot weather.

Railways, usually an ugly feature of every city, should be made less objectionable by boulevarding.

Open Spaces, Parks and Recreation Grounds.—In locating open spaces and parks, special consideration should be given to the preservation of places of natural beauty, such as woods, waterways, etc.

With the checkboard system of planning, a large amount of valuable ground is often wasted in the unnecessary provision of paved streets and passages. By carefully planning the main and secondary avenues, through traffic can be avoided and residential districts can be laid out in a far less costly manner, and part of the space occupied by paved streets being utilized for open spaces, tennis courts, and children's playgrounds.

Where individual gardens are not wanted, part of the land between the houses might be laid out as allotment gardens, or as gravel playgrounds, or as paved playgrounds, to prevent a lot of derelict gardens being attached to the houses.

People's parks are universally provided on the Continent within or close to the city's gates, namely, a large woodland garden or forest, intersected by drives and walks, and interspersed with spinnies and glades typical, as far as possible, of rural country.

It is the duty of every city to provide as early as possible, and before development makes the price of land prohibitive, suitable parks within easy access of the public.

Country life is acknowledged to be more healthful, more restful, more natural and less wearing than that of town. It should, therefore, be the aim of town planners to introduce into the home life of the worker conditions as far as possible which are common to the country, viz., quiet, the absence of distracting sights, sounds and influences and the introduction of works of nature.

It has become a very general rule in making arrangements for the development of land on modern lines in Great Britain to stipulate that one acre in ten shall be set aside as public or semi-public open spaces; this in addition to limiting the number of houses per acre.

Tramways.—The tramway system should follow the main avenues, and, as far as possible, each route should be linked up, one with the other, to form easy and suitable means of transit for the public to and from every part of the town. It should be arranged so that new lines could be constructed as the development of the town in a particular district required, yet be part of what would ultimately become a completed scheme.

The tramway system of Vienna is an admirable one. It has been described as follows: "The trams circle round the Ringstrasse, and the outgoing routes branch off like the spokes of a wheel. It soon becomes an easy matter to know where to leave the hub and take the necessary spoke."

Civic Centre.—The creation of a fitting civic centre is one of the most important matters which should be considered.

It should be dignified, impressive, whilst at the same time in harmony with the characteristics of the town itself and in keeping with the resources of the public.

Its situation should be as near the centre of the city as is possible, so planned that its architectural features and beauty can be seen from many points of vantage.

The buildings usually comprised in such a centre are the town and public halls, offices, sessions courts, museum, and art galleries, which, suitably designed and arranged in relation to each other, can, and should, form a civic centre worthy of the community.

Buildings—The Space about Same; the Limitation of the Number of Buildings per Acre; Their Height and Character.—The regulations with respect to buildings will be one of the most important parts of a town planning scheme, and will need very careful thought on the part of the local authorities.

In order to obviate overcrowding, it is essential that a maximum number of houses per acre should be adopted for different grades of property.

In limiting the number per acre it should be sufficient, in the case of land that is not planned out in detail, if it be stated that the rule should be so many houses to the acre, but that the requirements of the local authority would be satisfied if the average number was obtained over a certain area with due safeguards for the space about each house not being too small. There should also be a maximum number of houses stated, more than which should not be erected on any one acre.

Thus, if the number limited was 12 to the acre, the local authority might be satisfied if on any ten acres no more than 120 houses were built.

In residential areas the height should also be limited. Houses should not be built more than three stories, or more than a maximum height, to be defined.

It would seem desirable in planning an area that certain centres should be fixed where shops, schools, churches, institutes, and such like buildings should be grouped together.

The grading of districts and the planning out of the constituent parts which build up a city is an important consideration. The higher buildings should be fronting on the main arteries, gradually grading back to the residential property. Stores and offices will, of course, be placed along the main thoroughfares, and workmen's dwellings as close as possible to the factories in which the work people are employed.

Restrictions of Factories and Works to Special Areas.—It is very desirable in a town plan that the position of these should be fixed, and the people should not be allowed to place them where they like.

There will nearly always be natural places in a district which will be suitable for factories and workshops. Contiguity to the railway, easy gradients to same, and the position of the rivers, canals and streams should govern this in most cases.

It is usually accepted as an established fact that factories are unsightly, with untidy and dirty surroundings, but in many places, particularly in Bourneville, in England, the headquarters of Cadbury's factory, the reverse is the case. The whole of the surroundings of the factory and the workers' houses adjoining are laid out on garden city lines, and is a model of what can be done to make a factory district more amenable than is generally the case.

BUCKET LADDER EXCAVATORS FOR CANAL CONSTRUCTION.

While bucket ladder excavators are almost unknown in North America, they are extensively and with much success used in other countries for canal building. The canal, Alfons XIII., in Spain, joining Sevilla with the Atlantic, and projected to accommodate ships up to 10,000 tons capacity, is now nearing completion.

Four excavating plants, each consisting of one bucket ladder excavator, with portable water depot, two locomotives and forty square box dump cars, with the necessary track, switches, etc., built and supplied by the Orenstein-Arthur Koppel Company (general offices and plant, Koppel, Pa.), have accomplished the excavation in a surprisingly short time and at low cost.

The four bucket ladder excavators built for the construction of the canal, are designed for an actual capacity of somewhat over 200 cubic yards per working hour, excavating heavy soil. All four excavators are constructed to gauge and template, to make the repairs and the replacing of worn-out parts as easy as possible.

Excavator Working in Gravel Pit.

Bucket ladders of different patterns were supplied with each machine, firstly, for cutting down hills, thus fulfilling the same work as the steam shovel; and further, ladders for digging the bed of the canal to a depth of 50 feet, the digging being performed with buckets of special shape, mounted to a chain, which is supported by a ladder.

Two of the excavators supplied for this contract are fitted with the so-called "flexible" chains, and the others are equipped with "rigid" chains. The flexible chain is only in its upper part supported by the ladder, the lower part is hanging free, which means, that the chain has a fair amount of play in every direction. This is a great advantage should the buckets meet with large rocks, logs, etc., when digging, as on account of the flexibility of the chain, they will be able to jump over such obstacles or pass sideways. These excavators with flexible chains are constructed to dig to a depth of 33 feet below the rail level, and the embankments will have an inclination of 1 to 1.

The ladder is constructed of large dimensioned steel girders, well braced by diagonal and cross stays. The chain links are hand-forged, joined by connections made of a high-grade steel. Every fourth link carries a bucket of about 9 cubic feet capacity, making a total of 33 buckets to a machine.

The two excavators with "rigid" chains are constructed to dig to a depth of about 50 feet. This enormous depth necessitates the use of a bucket ladder of especially strong construction. The chains of this machine are guided all over by rollers working in ball bearings, thus cutting the embankments perfectly straight. The ladder can be set to work at depths of 25, 33, 40 and 45 feet. The adjusting requires a comparatively small amount of labor. The number of buckets furnished with the excavator is 26, of about 7 cubic feet capacity each. If these buckets meet with extraordinary obstacles, as rocks, logs, etc., which they cannot pass on account of the "rigid" chain, an hydraulic clutch automatically stops the movement of the chain, the engine running free until the obstacle is removed.

The lifting and lowering of the ladder on all the machines is effected by pulleys fitted to a double beam, as clearly illustrated on the cut. The transmission of power from the engine to the chains is made by means of tooth and cog wheels; strong springs are provided where it is necessary and advisable to diminish the effect of the shocks occurring during the work.

The excavator is constructed for running on track, the transmission from the engine to the axles being made by means of chains. It runs on 14 wheels, 10 supporting the front part and 4 the rear. The necessary power is provided by a large dimensioned boiler of locomotive type, located at the rear part. A water tank of about 750 gallons capacity, fitted underneath the boiler, supplies the necessary feed-water; further, coal bunkers are placed into this part of the machine, and a space for a counter weight, consisting of scrap rails, stones, etc., the quantity of which has to be increased the deeper the excavator is digging.

On a bridge joining the front and rear part the engine and a platform for the engineer are provided. All levers are worked from this platform, and this arrangement makes it possible to watch all parts of the machine during operation. The engine is of the compound type, having a rating of about 100 horse-power.

The earth lifted drops into a funnel chute when the buckets turn over the top part of the ladder. At the bottom of the chute a flap controls the filling of the dump cars, which are standing on the track, while the excavator travels along by its own power.

For each machine a transportable water car of 2,000 gallons capacity is in attendance. This car, combined with the water tank underneath the boiler, supplies sufficient feed-water for 10 working hours. The boiler is fed by an injector and a steam pump.

A three-rail track is necesssary for carrying the excavator, two rails for the front part, one rail for the four wheels of the rear part. Any 100 to 120-pound relaying rails can be used. Tracks for the dump car trains are running between these rails.

For moving the earth, stones, etc., 8 locomotives and 160 square box dump cars are used. The locomotives have cylinders 13″ x 16″, and work with 176 pounds boiler pressure. They are built with an underslung water tank, following the usual practice of the Koppel locomotives, as this arrangement puts the centre of gravity low and insures a smooth running of the locomotive, even if the track is not laid perfectly level. The tank will carry about 750 gallons of water and the bunkers about 3,000 pounds of coal. The dinkeys weigh about 54,000 pounds. The cars used are five cubic yard square box dump cars.

The track for the excavator is laid down parallel with the axis of the respective canal section. The machines are put to work, and, after digging a stretch of considerable length to the necessary depth, they will work their way back again, now running on a track which has been shifted further away from the edge of the canal, thus excavating another layer of 4 to 5 feet to the depth required. This shifting of the track backwards will be continued until the full profile of the canal is excavated. The earth drops into empty cars standing underneath the delivery chute, as mentioned above; as soon as one train is filled it is shifted away and an empty train is pulled along. A reasonable arrangement of the track will always provide empty cars in good time.

BARGES PROPELLED WITH PRODUCER GAS ENGINES.

A fleet of large self-propelled barges, 15 in number, to ply between New Orleans and the coal fields of Northern Alabama is of peculiar interest in that they are the first craft of their kind in America to be propelled by producer gas engines.

The barges are of steel construction, and are similar in design to those in use on the canals of Holland. Their measurements are as follows:—Length, 240 ft., width on deck, 32 ft., width at bottom, 28 ft., depth, sides, 8ft., depth, centre, 8½ ft. Their capacity is 1,000 tons. Draft, when fully loaded, 7 ft. They are propelled by twin screws driven by twin engines and have a speed of approximately seven miles an hour when fully loaded. The weight of each barge and equipment is close to 240 tons.

The screws are driven at 300 r.p.m., by two 75 h.p. vertical producer gas engines. Gas is furnished by a 150 h.p. producer. The fuel used for the producer is what has heretofore been a waste coke from the ovens of the Birmingham district and which consequently is secured at a very low price. This coke is practically pea size. It has a calorific value of about 11,000 b.t.u., and the consumption is approximately 1 lb. per horse power. Bunkers are provided to hold about 15 tons of fuel. Each producer is equipped with scrubber, gas tank, tar extractor and is fitted with water bottom.

Fig. 1.—First of Fleet of Fifteen Barges, Propelled by Producer Gas Engines.

While the main power plant is of primal interest the auxiliary power equipment of the barge also merits mention. This consists of a 9 h.p. gasoline engine, which drives a centrifugal pump handling the ballast and bilge water, a blower, an air compressor and a 5½ k.w. direct current generator. Current is used for electric lights throughout the boat, fans in cabin and engine room, a 3,200 candle-power search light and a 5 h.p. motor. The arc light is mounted on the roof of pilot house and galley, which are immediately over the engine room. The motor is for operating an anchor winch. The generator is so mounted that when the large engines are running it may be belt driven from one of them. A second 4 in. centrifugal pump is also installed to be driven by one of the large engines through friction wheel contact.

A decided advantage of the self-propelled barge for use in these waters is that they can negotiate the numerous locks on the Warriors and Tombigee Rivers in much less time than if towed. Each lock can be passed in 20 minutes by these vessels, whereas more than an hour would be consumed by the towed fleet system.

The barges will make the trip from the mine region to New Orleans in 72 hours and with all 15 vessels in service, it is estimated that coal will be moved into New Orleans at the rate of 50,000 tons a month. Added revenue will be de-

Fig. 2.—Showing Barge Being Loaded.

rived by the barges carrying freight on the return trip to the coal field. All the power equipment for the barges—engines, gas producers, motors, generators, pumps, air compressors, etc., was designed and furnished by Fairbanks, Morse and Company.

SAWDUST FOR FLOORING.

Floorings are now being made out of sawdust concrete. The cement used consists of a solution of magnesium chloride to which pulverized magnesia is added. The sawdust is then used in any desired quantity. Floors manufactured in this way are more resilient than concrete, and are not good conductors of heat. They wear well, and do not burn, charring under the fire test.

WATER WASTE IN NEW YORK CITY.

During 1911 and 1912, on account of a threatened shortage in the supply, a vigorous campaign to prevent water waste was carried on in New York city. The methods generally employed were as follows:—

(1) The attention of consumers was called to the necessity for checking waste.

(2) A house-to-house inspection was carried on in order to detect and repair leaks.

(3) An examination was carried on with the object of locating and repairing underground leaks.

(4) Connections were metered where the cost of metering and the existing conditions of the supply warranted this measure.

The results obtained were noteworthy in many respects. The estimated daily reduction in consumption in Manhattan and the Bronx reached a maximum of 71 million gallons in August, 1911, averaged 65 million gallons for the last six months of 1911, and almost 50 million gallons for the year 1912. The aggregate value of the water thus saved, if figured at meter rates, $133 per million gallons, would be nearly $6,500,000, while the total cost of the work was only $167,000.

BOOK REVIEWS.

Switches and Switchgear.—By Prof. R. Elder, translated by P. Laubach, A.M.I.E.E. Publishers, Constable & Company, Limited, London, W.C. 397 pages; 6 x 9 inches; illustrations and tables; cloth. Price, $4.50 net.

Reviewed by M. B. Watson, B.A.Sc.

Ever since electricity became of commercial importance no branch of the art of applying this force has received more attention than the switchgear used for opening, closing and connecting together of circuits; and rightly so, because in the early stages of the science this was the operation which was of necessity performed manually in the control of circuits and the operator's protection was of primary importance; also in the present day of high tension electrical installations it has been found necessary to protect the apparatus in the circuit as well as the operators, hence the necessity for automatic switching devices, and the scientific study of the whole subject of switching.

The volume under discussion treats mostly of present day practice although confined largely to continental European practice touching somewhat on English and slightly on American practice. The subject discussed is one on which there is much variety of opinion as there is variety in the types of apparatus manufactured, and it is a task of no mean proportion to summarize and give intelligent descriptions of practically all types of switches and switchgear on the market. This book is, however, the first really comprehensive work on the subject of switchgear that has been presented in English language.

The opening chapter contains a few general remarks on the requirements of and the materials used in the manufacture of switches. Chapter 2 deals with the materials most commonly used for the manufacture of switches, giving tables and formulæ for the design of bus-bars, cables, cable terminals and switch blades for different allowable rises in temperatures. Chapter 3 gives descriptions, formulæ and tables for the design of the current carrying parts of switches, such as blades, spring clips, and brush contacts with regard to both current carrying capacity and mechanical strength.

In chapter 4 we find a discussion of low and medium voltage switches for small and large currents, also data for the mechanical design of springs for use with quick opening switches. There are also empirical formulæ for the design of the assembled switches, accompanied by tables for use with the formulæ according to European practice. Note is also made of the prevalence of the brush contact switch in Europe in contrast to the multiple blade knife switch in use in America. This chapter is apparently somewhat revised by the translator.

Chapter 5 gives data on high tension switches. A great deal of this chapter is relative to the older types of switches for what is known in American practice as medium voltage, i.e., between 1,000 and 6,000 volts, while there is practically no data of value on switches for voltages above 50,000. However, there are thorough descriptions and discussions of the characteristics and theories of operation of medium voltage switches, including a discussion of oils for use in oil switches, also of the mechanical and electrical properties of porcelain as an insulator. A good discussion of the relative merits and reasons for the use or disuse of the different types of switches is also included.

Chapter 6 treats of fuses, discussing the several materials used in their construction, including formulæ, tables and curves for the design of fuses for different conditions. This part of the chapter is very complete. The descriptions of fuses in use are practically all of European types and a few obsolete types. None of them are used to any great extent in America.

Chapter 7 describes in detail, the construction and operation of automatic and self-acting switches, being well illustrated with cuts and circuit diagrams. The types most fully discussed are overload cut-outs, no-load circuit-breakers and reverse current cut-outs, also combinations of the above at present in use and on the market. The theories of operation and the circuit diagrams are especially valuable, though the types of construction described are wholly according to European standards. Practically no data of value to designers or manufacturers is given.

Chapter 8, which is the part of the book on which the most pains have been spent, begins with a practical analysis of the characteristics of motors during starting, developing examples of designs for starters and controllers to meet the different conditions of starting both A.C. and D.C motors. Data, equations, tables and curves for the design of generator regulators, line voltage regulators and armature and field regulators for variable speed motors are given, also descriptions and operating characteristics of the above. A discussion of designs for resistance feeder regulators is given as are also tables, formulæ and discussions of resistance materials and typical designs of resistances to meet different conditions of load. This subject is quite fully covered with the exception of data on dimensions of the assembled apparatus. A fine analysis of resistances with methods of assembling and mounting same is also included. A good general description of automatic and relay switches is given, also descriptions of starters and controllers of the cylinder type, such as traction controllers.

The final chapter, dealing with accumulator switches, gives diagrams and explanations of hand-operated and automatic end cell switches, constant voltage regulators, charging and booster regulators and remote control and indicating switches, also the anti-arcing devices in use with same.

On the whole the book contains valuable information for erection and lay-out men but little of value to the designer. There are many references to foreign technical papers and books. One item which the translator might have improved considerably is the use of units, which are not at all consistent. English units, or parallel English and metric units should have been used throughout, also in tables of areas of cross-sections of conductors, etc., the square inch, instead of the circular mill, has been taken as the unit.

In many parts of the book the matter is poorly arranged, the continuity being lost in several instances. Some of the cuts used are not of the best, but the line diagrams are both plentiful, intelligible and well produced.

The Resistance of the Air and Aviation.—By G. Eiffel, translated by Jerome C. Hunsaker. Published by Constable & Company, London, Eng. 442 pages, 10 x 12¾ inches; 137 illustrations in the text, 27 plates; cloth. Price, $4.50 net.

Reviewed by J. E. Burns, B.A.Sc.

The aeroplane, like the hydraulic turbine, has been, and is being, developed by two classes of experimenters, who work in very different ways. One is the mechanic, often of consummate skill, who pins his faith to the method of trial and compromise. The other is the engineer, or man of science, whose design is always rational and based on facts; who often suspends operation of a direct nature for years in order to ascertain the facts by which he may proceed. To the latter class belongs M. Eiffel, the author of the work under consideration. As early as 1902 he began experimenting upon the resistance offered by air to moving bodies by means of a "dropping apparatus," and in 1910 published the results of his labor with a review of the subject.

The present work is a description of a method of investigating the resistance offered by air to moving objects which has been developed by M. Eiffel, together with the results obtained by the use of his methods in an immense amount of painstaking experiment carried out in an aerodynamic laboratory established by the author at the Champ de Mars, in Paris, and in a much larger but similar laboratory established later at Auteuil.

The book is divided into two parts, the first of three chapters. The first chapter describes the laboratory and method followed, and presents a complete calculation of the resistance of a given plate. The second chapter presents general results obtained from experiments on plates of various form and on many bodies of different shapes. Chapter III. presents results obtained from model aeroplane wings and complete models of many well-known types of machines The second part is a supplement of the first, containing the numerical results of the experiments described, and the general conclusions of the author.

Much of the work of M. Eiffel is already classical, for he has demonstrated beyond doubt that, to use his own words: "In aeroplane design, careful tests with a model aeroplane, or with model wings, permit the designer to predict the conditions of normal flight."

To those who are interested in aerodynamics or in aviation the book will prove of profound interest, though it is far from easy reading. The experiments recorded give ground for believing that the problem of stability in aeroplanes, the bugbear of the birdman, is capable of solution, and through the consequent safety of flight the future of the art is established. Even at the present date very gratifying results have been obtained in actual flight by designs growing out of the Eiffel experiments. Although the author does not indulge in any mathematical theory, the work is intensely technical, but it is written in a clear and pointed style, and is one of the most pregnant books on the subject in print. We may thank the translator for having so well rendered a valuable work into English.

The Gas Engine Handbook.—By E. W. Roberts, M.E. Published by the Gas Engine Publishing Company, 224 E. 7th Street, Cincinnati, Ohio. 323 pp.; 4½ x 7 inches; 80 line illustrations; bound in limp leather. Price, $2.00.

This little pocket manual appears in its seventh edition, the publishers stating that it is entirely re-written and enlarged. It contains much information that gas and gasoline engine men find indispensible and frequently find difficulty in securing in the form of a book of reference. The text comprises three parts: description, design and points concerning operation, which include installation, testing, troubles, selections, etc. The reading matter is attended by the usual tables on areas and circumferences of circles, strength of materials, specific gravity of metals, etc.

Although the handbook has a fair index, the text is devoid of sub-headings which are generally considered a necessity in engineers' handbooks. When twenty or more pages are devoted to a single chapter without a single sub-heading, such as the chapter on "Testing" on can only infer that the book might have been greatly improved in this respect, if it is to fill the requirements of a handbook. The information, however, is carefully compiled, although little of it is new, and for engineers and designers there are few books in print that contain in better form, with the exception of the deficiency mentioned above, the results that are to be derived from a close study of gas enginery.

In the chapter on design the discussion starts with a chapter on the indicator diagram, and in another chapter shows the method of arriving at the general dimensions of a motor desired to fulfil certain conditions. Then follow chapters on the design of the specific parts such as the cylinder, the piston, rods, shafts, etc. Of special interest, however, is the chapter on frame design in which not only are the formulas given and explained in detail, but a method of design without the use of the general formulas is given. In the chapter on flywheels, the treatment has been brought up-to-date, without being pedantic. Governor design in its especial application to the gas engine has been treated quite fully and to an extent not found in any other work on the subject.

Of more than ordinary interest is the chapter on the design of two-cycle engines, this chapter in many ways tending to lift a veil of mystery from this subject. It gives not only the formulas for design but shows that instead of being an everlasting puzzle, the design of the two-cycle is a very simple matter indeed.

There is a chapter on the design of aeroplane motors in which there is given a few simple rules for the design of engines of the lightweight required in this service. While the author does not go into minute details on this subject as much as might be desired, it is touched upon in the chapters on the design of details.

In the third part a chapter on installation describes the arrangement of the engine room and gives many useful and practical hints on the arrangement of piping, cooling tanks, meters, etc., and goes into the whole matter of engine room fittings in a thorough manner.

The chapter on installation is followed by others on starting and stopping, care of gas engines and a very full and complete chapter on troubles. The latter is arranged under various heads and gives both the cause of the trouble and the remedy.

The next chapter on testing is the most extensive in the book. It describes in detail the method of making a complete test to the extent of a thermal analysis or the determination of a complete heat balance. In this chapter there is described the construction and the operation of the gas calorimeter, the manograph, etc. A form for a test log and an-

other for a test report leaves nothing undone to make the treatment of this important subject, the most complete.

The book ends with a chapter on the selection of a gas engine, which is well worth reading by the intending purchaser of a power plant.

Principles of Setting Out—Securing and Tooling Operations, for Engineering (Machinist) Students and Apprentices, and Students in Manual Training in Metal Work. By Alfred Parr, lecturer on Workshop Practice, University College, Nottingham. Published by Longmans, Green & Company, London. 280 pages; 6 x 9 inches; 250 illustrations, 1913. Price, $1.50 net.

Reviewed by Chester B. Hamilton, B.A.Sc.

The mechanical execution of this book is good. The numerous illustrations, many of them half-tones, are well selected for their purpose. The composition of the book has two large faults, however. In selecting material the author has wandered over almost the length and breadth of machine shop practice. Probably this was intentional, for in the introduction it is said:—

"The man who sets out work must be well acquainted with the construction and use of such appliances, and with the proper tolerance and allowances for various classes of fits, as well as with the best methods of holding work and the proper cutting speeds. No apology is, therefore, needed for the inclusion of such information in a book on setting-out."

Following this train of thought, the author might say that a good setter-out should have some knowledge of elementary mathematics, and proceed to instruct him, and that he should be a sober man, and, therefore, include a temperance lecture. However, it should hardly require argument to prove that information on a specialized subject should apply definitely to that subject.

The other point to be criticized in this book is more serious. There is an absolute and total lack of logical order or arrangement of subject matter. The author flits from one unrelated subject to another with the happy unconcern of a butterfly in a flower garden. The most provoking point is that the material itself is really good, and a little careful editing and arranging in logical form would make the work really valuable.

Broadly speaking, machine work may be divided into three classes by its relation to setting-out: (1) Where various lines and marks are placed on the rough stock and the tool is made to conform to them by the skill of the operator. (2) Where the copying principle is used and the actual form of the finished work is given by the tool used. Examples: Gear-cutting, form-milling, planing or turning with form tools, punch and die work, etc. (3) What is commonly known as jig work, where the stock is held in some fixture, which usually also guides the tool, and by giving tool and work definite relative positions produces work of superior accuracy in an easy way.

In the strictest sense it is only in the first case that the work is set out or marked off. In the second case this is done only on the tools when they are first made, and in the third it is the holding apparatus or jig which was marked off.

Concrete Roads and Pavements.—By E. S. Hanson. Published by the Cement Era Publishing Company, Chicago, Ill. 227 pages and advertising; 4½ x 7½ inches; illustrated; cloth. Price, $1.00, postpaid.

This book opportunely appears in the midst of a season when the construction of roads is receiving the greatest attention in history, and when there is an acute demand for carefully compiled data on road materials, construction and maintenance.

The subject is treated in thirteen chapters, containing general information on concrete as a road and paving material for rural and urban highways, supplemented by examples descriptive of some roads in Michigan that are claimed by road engineers to be deservedly famous for their careful construction, and of similar roads in Illinois, where valuable data pertaining to costs is also given. The theory and practice of joints, problems relating to bridges, culverts, sidewalks and curbs and gutters are admirably dealt with, and Chapter XI., describing tests made on concrete as a paving material, contains results and methods with which every road engineer should be familiar.

The work is supplemented by twelve appendices, dealing with specifications for various pavements, for bridges, culverts, etc., which obtain in the States mentioned above. The book is admirably edited, as one might expect, as the author is the editor of The Cement Era. His presentation of the subject is concise and carefully condensed, and as such will be of great value as an up-to-date treatment on concrete road construction.

Manual of Industrials, 1913.—(Fourth annual number). Published by Poor's Railroad Manual Company, 535 Pearl Street, New York City. 2,268 pages; 6 x 9 inches; 124 pages of index. Price, $7.50, postpaid.

This manual is associated with two other manuals published by the same company, viz., Railroad Manual and Manual of Public Utilities, the one under consideration completing the set for 1913. It refers entirely to manufacturing, mining and miscellaneous corporations. It contains an exhaustive list of new companies, and is particularly valuable for its comparative and analytical statistics.

The Railroad Manual is a well-recognized standard authority on railroad operations, and the present constitutes the forty-sixth year of its existence. The other manuals are more recent publications, but are almost all equally recognized in their respective fields. The Manual of Public Utilities was reviewed in the Engineers' Library of *The Canadian Engineer* in the issue of June 26th, 1913. The publishers claim that the three books contain over 6,000 pages, thereby superceding any other manual in volume of information The price of the three volumes complete is $20.00.

Each of the three volumes for 1913 is a decided advance upon its corresponding predecessor of last year.

Industrial Plants, Their Arrangement and Construction.—By Charles Day. Published by the "Engineering Magazine," New York. 294 pages; 5 x 7 inches; illustrated; cloth. Price, $3.00 net.

This little book in twelve chapters is a product of Mr. Day's wide experience as consulting engineer in the construction of some most successful plants and structures. Chapters I. to VIII. inclusive are founded upon a series of university lectures covering the broad industrial principles upon which the arrangement and the planning of the industrial plant are based. Chapter IX. goes more into the specific problems entering into machine shop practice. Chapter X. depicts the advantages of logical planning by a number of descriptions of plants in operation, illustrative of the trend of modern practice. The two closing chapters admirably supplement the work by a treatment of the relationship between the client and the engineer, dealing from the standpoint of the former, with the value of an engineering organization to a proposed plant layout, and upholding for the latter a considerate and judicious opinion relative to compensation for engineering services, and the preferred basis for reasonable commission.

The book does not guarantee a plant to be successful. It is well known that inefficient management is the governing factor; but the plant that is arranged along the line

of Mr. Day's elucidation of the many factors covering the project and the product from its raw state until the bill of lading is affixed, will prove to be one susceptible to economical management in its own field.

Excavating Machinery.—By A. B. McDaniel, B.S., Assistant Professor of Civil Engineering, University of Ilinois. Published by McGraw-Hill Book Company, New York City. 327 pages; 134 illustrations; 6 x 9 inches; cloth. Price, $3.00 net.

The book is a careful treatise upon all types of excavating machinery and apparatus used in modern practice, and covers its subject in two parts, supplemented by two appendices. Part I. deals with scrapers, graders, and shovels of various kinds, while Part II. takes up the subject of dredges and excavators. A good deal of usahle information concerning costs relating to the operation of excavating machinery has been included and will be of service. Although the condition and circumstances dependent upon such work are so variable that the cost data can be of very general value only, it nevertheless should be serviceable regarding efficient operation of machinery and the systematic arrangement of work.

In his introductory paragraphs the author lays stress upon the importance of closer attention to cost, and advises the keeping of accurate and complete records of cost of all work, by engineers and contractors alike, as valuable data for future use. He has supplemented each section by carefully selected bibliographical references, to which the reader may turn for additional information.

PUBLICATIONS RECEIVED.

Foundry Cupola Gases and Temperatures.—By A. W. Belden, Bulletin No. 54, United States Bureau of Mines, Washington, D.C., 29 pages; illustrated with photographs and drawings.

Elevators and Warehouses.—Eighty-seven page list of licensed elevators and warehouses in the Western Grain Inspection Division. Issued by the Department of Trade and Commerce.

Ontario Land Surveyors.—Annual report of the association and proceedings of the 21st annual meeting, including reports of committees, papers, examinations papers and membership.

Manitoba Department of Public Works.—Report of the Department of Public Works of Manitoba for the fiscal year ending November 30th, 1912, by Colin H. Campbell, Minister of Public Works, Winnipeg, Man.

Summary of United States Commerce and Finance for June, 1913.—Covering the foreign commerce of the United States and its non-contiguous territories. Published by the Department of Commerce, Washington, D.C.

The Canadian Chamber of Commerce, London, England.—First annual report of the Council "for the encouragement and promotion of Anglo-Canadian trade and commerce and the development of Canadian industries by British capital."

The Territory of New Quebec.—Extracts from reports on the district of Ungava, recently added to the province of Quebec. Issued by the Department of Colonization, Mines and Fisheries, Quebec, Que.

Revenues and Expenses of Steam Roads in the United States.—Bulletin No. 54 of the Inter-State Commerce Commission. Prepared by the division of Statistics from the reports of expenses and revenues of steam railway operations during the month of May, 1913. Published by the Commission.

Commission of Conservation, 1913.—Report of fourth annual meeting held at Ottawa, January 21st and 22nd, containing reports of committees on public health, minerals, forests, fisheries, waters and water powers; papers on oyster farming, forest surveys, claybelt conditions of New Ontario, smoke prevention, etc.

Coal and Power Investigation, Sask.—Report by R. O. Wynne-Roberts. 133 pages; 10 plates and maps. A compilation of data and conclusions therefrom resulting from an inquiry into the practicability of producing power at coal centres and distributing it throughout the province. Published by the Board of Highway Commissioners, Regina, Sask.

Portable Electric Mine Lamps.—Technical paper No. 47, Bureau of Mines, United States Department of the Interior. Written by H. H. Clark. Discussing the advantages that such lamps possess and suggesting some characteristic which they ought to have as now designed and constructed, portable electric lamps having been already introduced in a number of mines.

Investigations of Detonators and Electric Detonators.—By Clarence Hall and Spencer P. Howell. Bulletin No. 59 of the United States Bureau of Mines, Washington, D.C, 72 pages; illustrated. Numerous tables. Containing a comprehensive treatise on the theory of detonation of high explosives and the result of tests for determining directly and indirectly the strength of various electric detonators.

Brick Fire Places.—A handsomely illustrated booklet of 32 pages containing suggestions for modern designers of interior woodwork and furnishings, in the matter of brick as a material for fireplaces. The compilers have used Arts and Crafts motifs in their design and by the neat decorative schemes which the booklet displays, much has been added to the architectural effects to which the fireplace lends itself. Published by the Thomas Moulding Company, Chicago, Ill.

Report of Minister of Mines.—Annual report by Mr. F. Robertson of mining operations for gold, coal, etc., for 1912 in the province of British Columbia. Contains statistical tables of mineral output, and shows in detail the actual mineral production of the past year, as based on smelter or mill returns; also a summary of the production of each of the last four years, thus illustrating by comparison the progress made in productive mining during that period. Issued by the Bureau of Mines, Victoria, B.C.

The Nickel Industry, with Special Reference to the Sudbury District, Ont.—By A. P. Coleman, Ph.D. Professor of Geology, University of Toronto.—Issued by the Department of Mines, Ottawa. A book containing 206 pages; 6½ x 10 inches; well illustrated; 53 plates, 14 figures, and 8 geological maps. The development of the nickel industry in the Sudbury district is a prominent feature in the history of Canadian mining industry. Dr. Coleman has made a very thorough investigation extending over a period of three years, and the information gained thereby, together with his own comprehensive knowledge of the geology, has enabled him to produce a very excellent monograph, which covers in every detail the activities of the industry in the Sudbury region. The accompanying maps of the district and of the more important mines, together with the descriptions of all the known nickel ore deposits in Ontario, and concise accounts of methods in vogue for the mining and melting of nickel ores, go to make the publication one of greatest value.

CATALOGUES RECEIVED.

Mechanical Dwarf Signal.—Illustrated catalogue on G. R. S. mechanical dwarf signal and R. S. A. design. Issued by the General Railway Signal Company, Rochester, N.Y.

Train Dispatchers' Telephone Selector System.—Illustrated 35-page catalogue. Issued by the General Railway Signal Company, Rochester, N.Y.

Railway Motor Cars.—Illustrated catalogue dealing with Rockford motor cars. Issued by the Chicago Pneumatic Tool Company, Chicago and New York.

Peebles' Motor Converters.—Illustrated catalogue dealing solely with the company's converters. Issued by Bruce, Peebles & Company, Limited, Edinburgh, Scotland.

Lucal Liquid Fuel Company issues a 24-page illustrated catalogue on Lucal appliances for burning oil. The Lucal Liquid Fuel Company, 203 Hope Street, Glasgow, Scotland.

Fuel Oil Data.—Twenty-page illustrated catalogue on various types of installations and information regarding the burning of fuel oil. Issued by the Tate, Jones & Company Inc., Pittsburg, Pa.

Couplings and Pulleys.—Illustrated catalogue dealing with friction clutches, couplings and wood pulleys. Issued by the Allis-Chalmers Manufacturing Company, Milwaukee, Wis., and Toronto, Ont.

Compressors.—Illustrated catalogue dealing with enclosed, self-oiling, single-stage, steam and belt-driven compressors. Issued by the Chicago Pneumatic Tool Company, Chicago and New York.

General Catalogue.—Water metres, hydrants, sluice valves, tanks, sewerage fittings, pumps, hot water and steam fittings, etc. 272 page catalogue. Illustrated. Beck and Company, Limited, Hydraulic, Sanitary and General Engineers, London, England.

Engineering Instruments.—155-page illustrated catalogue, showing the various types in their wide line of engineering instruments. Issued by Bausch & Lamb Optical Company, Rochester, N.Y., through the Toply Company, their Canadian representatives at Ottawa.

The Squires Steam Trap.—An 8-page folder descriptive of the trap giving directions for connections and operations under various fittings, showing section illustrations and tables of capacity. Representatives in Canada, Canada Allis-Chalmers, Limited, Toronto.

Continuous Current Motors and Dynamos.—Illustrated catalogue dealing with continuous current motors and dynamos, 2 and 3-phase motors and dynamos, continuous current starters, alternating current starters, motor generators, etc. Issued by Wright & Wood, Limited, Century Works, Halifax.

The Foos Pumping Engine.—An illustrated 12-page booklet descriptive of the application of the Foos gas engine for all kinds of pumping service, is Bulletin 89 of the Foos Gas Engine Company, Springfield, Ohio, containing a number of tests from deep-well, irrigation and ordinary water supply systems.

The Monahan Trench Digger.—An illustrated catalogue descriptive of this and other Monahan machines, e.g., back-filler, pipe-laying derrick and steel forms for concrete manholes and catch basins, of which Wm. Heggie, Joliet, Illinois, is the manufacturer and W. B. Louer, 900 Old Colony Building, Chicago, is sales manager.

The Imperial Positive Water Meter.—A twenty-two page catalogue handsomely printed and illustrated in colors dealing with the characteristics, construction, maintenance, of the type, including also price list and shipping particulars. Issued by the Manufacturers, Beck and Company, Limited. 130 Great Suffolk Street, London, S.E.

Ceresit.—A handsomely printed booklet descriptive of the product of the Ceresit Waterproofing Company, and containing information on the waterproofing of concrete. The attractive catalogue covers many topics in an individual manner and will be found a helpful addition to engineers' and contractors' bookshelves. Published by Ceresit Waterproofing Company, 446 Commercial National Bank Building, Chicago.

COAST TO COAST.

Windsor, Ont.—The Hydro-Electric Power Commission has decided on the route of the transmission line to Windsor, and has the location almost completed between Chatham and this city. The foundations have been also placed between Belle River and Chatham for the transmission line towers.

Quebec, Que.—The Canadian Northern Railway has made it known in this city that the company expects to be operating grain trains over its line from the Canadian North-West to Quebec this fall. All connections between Quebec and Ruel, Ont. (384 miles) will be ready for train service early next month, and the road from Sudbury to Port Arthur opened for traffic a month later, which will give the Canadian Northern Railway direct communication from Quebec to the end of its present line in the North-West.

Edmonton, Alta.—Roused by recent discoveries of rich, undeveloped mineral, asphalt, gas and oil resources in various parts of the western provinces, scores of prospectors and experts, known in many camps throughout the United States and Canada and Mexico, are making exhaustive searches in the Peace River country and other northern districts. Central and Southern Alberta are also being prospected. The Dominion and provincial governments likewise have their experts in the field. Seventeen parties are prospecting in the Canadian Rockies, west of Edmonton, but most of the work at present is being carried on in the north country.

Sarnia, Ont.—For some time past Sarnia's water supply has been showing a serious state of pollution, as mentioned in last issue of *The Canadian Engineer*. So much is this in evidence that the provincial health authorities have ordered that double the quantity of chlorine be added to the water supply. This has been done, but in several instances where tests of the water have been made the pollution continues to exist. This leads to the opinion that there must be a break or leak in the intake pipe, through which sewage is being allowed to find its way into the waterworks well, and thence into the waterworks pumps.

Le Pas, Man.—That the Saskatchewan River, working in conjunction with the Hudson's Bay Railway from Le Pas, will prove of immense value to farmers and other shippers as far west as Edmonton, is the opinion of L. A. Voligny, Dominion Government chief engineer, in charge of the surveys and works in connection with the navigability of the Saskatchewan. Work is now completed to Le Pas, and orders have been received to continue to Grand Rapids. A channel ten to twenty feet was found the entire way from Cumberland House, and hardly any extra work was necessary, though some dredging will be required about Moose Lake and Cedar Lake, and this will be started immediately, as will also the construction of a wharf at this point. The government insisted on Prince Albert building a lock at LaColle Falls, and this indicates that the fullest use is to be made of the North Saskatchewan as soon as possible. Mr. Voligny estimates that the entire project can be carried through within five years, and no doubt eventually through Winnipeg. In conjunction with the government road to the Bay this navigable channel, tapping all the northern part of the Canadian prairie west, will go a long way to reducing the cost of marketing grain, and the cheaper water rates should bring freight tariffs of the transportation companies into line. Nor is this all. Mr. Voligny feels confident also about the navigability of the south branch of the Saskatchewan, which, he says, will soon receive attention. All the railway bridges have been built to this end, and all that is required is a demand by cities and towns along its course. Curiously enough, these municipalities appear apathetic as regards navigability of

the south branch, while their neighbors on the north branch have been agitating for a long time, and now get served first.

Calgary, Alta.—Forty-six line elevators will be built in Alberta this year in time to handle this season's crop by the Alberta Farmers' Elevator Company, Limited, authorized under the Farmers' Elevator Bill, passed at the last session of the Alberta legislature. The work of construction of half of these elevators is in progress now, and materials for the others have been purchased and are on the ground at the various locations. For the erection of these elevators, forty-six local companies have been formed, which are under the direction of the parent company. The preliminaries for all this had been arranged by the provisional directors of the Farmers' Elevator Company, and to ratify and confirm the action of those officials and to properly launch the company a meeting of the shareholders of the company was held recently. The necessary confirmation of the work of the provisional directors was accorded, the company was organized upon a permanent basis, and the Minister of Agriculture assured the shareholders that the necessary money to pay for the elevators was ready and waiting their pleasure.

Sault Ste. Marie, Ont.—The installation of the chlorination plant of the Tagona Water and Light Company has just been completed, and was immediately put to work. Inspection showed it to be in excellent order. Its completion dates just twenty-eight days from the issuing of the order for its construction. It was ordered as a result of the investigative work of Dr. Amyot and F. A. Dallyn, C.E., of the Provincial Board of Health. Analyses of the water taken at various intervals across the river, which is the source of the town's supply, showed the presence of bacteria. Up to the present time twenty cases of typhoid have been reported, two of which came from the neighboring municipality of Steelton, and one, it was found, had come from an outside point along the line of the Algoma Central Railway. So far, only one death has occurred.

The two municipalities of Sault Ste. Marie and Steelton are devoting their attention to choosing the most suitable place for a joint intake pipe which will serve the two towns when the present franchise of the Tagona Water and Light Company expires, which will be in 1914.

Ottawa, Ont.—The chief architect's branch of the Public Works Department has issued the conditions for the competitive designs for the new departmental and courts buildings. Not only is there the booklet containing the conditions, but there are also extensive plans of the grounds and a set of beautiful half-tones of the site between Wellington Street and the cliff. One feature of the conditions is that the successful architect will erect the buildings. The conditions state that the successful architect will be allowed regular fees and must maintain an office in Ottawa while the work is in progress. The conditions point out that the work on the new buildings will start very soon after the final award has been made. The final designs entered in the competition will be on exhibition in Ottawa with the author's name on them for seven or more days subsequent to the award. The plan for the treatment of the site prepared by Mr. E. White and Sir Aston Webb is submitted, but the conditions leave the competitors a free hand to develop their designs regardless of that plan. The conditions provide that all plans be delivered to Ottawa by January 2nd, 1914. The award of the preliminary competition will be made as soon as possible afterwards. The assessors will be Messrs. T. E. Collcutt, J. H. G. Russell and J. O. Marchand. The complete scheme is to build a supreme court, exchequer court, railway commissioners' court, and the necessary offices in connection with these courts, also a block or blocks of departmental buildings having 500,000 superficial feet of floor area The competition is restricted to architects who are British subjects practising in the British Empire.

Toronto, Ont.—Acting City Architect G. F. W. Price and Deputy Fire Chief J. C. Noble were very favorably impressed with the new system of fireproof flooring, consisting of gypsum and wood chips, reinforced by wire cables, and capable of carrying a live load of 125 pounds per square foot. It is claimed that the new floor is much lighter and cheaper than reinforced concrete, inasmuch as it does not require such heavy steel reinforcements. Experiments with the material are attracting much attention from engineers and architects, and a specially severe test recently conducted in New York by Messrs. Perrins & Miller, of Columbia University, in which the average temperature maintained for three hours was 1,757° F., the floor sustaining its load and withstanding the test in a most admirable manner.

St. Catharines, Ont.—Port Weller is to be the name of the new townsite at the Lake Ontario entrance to the new Welland Ship Canal, described in *The Canadian Engineer* for August 21st. This decision has been reached by the syndicate that has purchased several acres on each side of the new harbor. It was supposed that the harbor would be called Port McCalla, on account of an old private park there, but the above choice has been made in honor of J. L. Weller, of this city, chief engineer in charge of the canal, who has done all the planning in connection therewith. The syndicate has purchased all the land adjoining the entrance of the canal, the Government is beginning the erection of an office building on part of the land which has been expropriated, houses and stores will be erected without delay to provide for the workmen to be employed on the canal, the owners of the property hope to secure a factory, and expect that before long a thriving town will be springing up where now are only farms.

Vancouver, B.C.—In order to facilitate the driving of the 22 by 30 foot double-track Canadian Pacific Railway tunnel, of five miles long, through Rogers' Pass, at the summit of the Selkirks, Messrs. Foley, Welch & Stewart, the contractors, have decided to adopt a new method, which will be watched with great interest by the engineering world. The expedient consists of first boring a parallel tunnel, 7 by 8 feet, for virtually the same length, and from this tunnel cross-cuts will be made at short intervals to the site of the proposed large tunnel. This will enable gangs of men and machine drills to attack the work simultaneously at scores of points. Incidentlly, the "pioneer" tunnel, as it is called, will also provide ventilation, and will, for a considerable time, provide an exit in removing the rock material. The railway company and the contractors have figured that it would take too many years to construct the large size bore, starting only from the two ends.

Montreal, Que.—Although companies like the Dominion Steel Corporation and the Nova Scotia Steel and Coal Company are experiencing an active demand for their entire output of iron, the situation is somewhat different with the merchant furnaces. Companies such as the former are able to use up in their own finishing departments the greater portion of their output of pig iron. Dominion Steel practically uses its entire output; Scotia has but a small quantity for sale, and has no difficulty in disposing of it. The 300-ton Midland furnace of the Canada Iron Corporation is cold, and will remain so until the situation improves. The 150-ton furnace, however, is kept actively employed. The Deseronto plant is operating full blast, as are probably most other plants throughout the country. At the same time, Canadian plants now have to meet the low prices being made by American furnaces. Buffalo has been selling at $17.25, Toronto, and it is said quite a large tonnage was disposed of. The Steel Company of Canada is reported selling at $17.25, Hamilton, equivalent to $19.25, Montreal.

TRACTION ENGINE COMPETITION IN BELGIUM.

According to its weekly report the Department of Trade and Commerce, Canada, is informed that the Belgian Minister for the Colonies has organized an international competition of traction engines and other ploughing machines. A sum of 70,000 francs will be appropriated for the best machines, and indemnities up to 15,000 francs will be granted to the competitors who have received no orders.

Canadian manufacturers are invited to take part in this competition, which will be held at Chassart, near Fleurus, Belgium, from the 24th to the 27th of September next.

PERSONAL.

FRANK BARBER, C.E., bridge and structural engineer, Toronto, has recovered from an illness extending over several months and is at his office again.

ERNST POENSGEN, general manager of the tube department of the Phœnix Steel Works, Dusseldorf, Germany, arrived this week in New York City. He will make a tour of United States and Canada in his firm's interests.

A. WOODROFFE MANTON, M.I.C.E., B.Sc., resident engineer in Constantinople for the engineering firm of S. Pearson & Son, Limited, with headquarters at London, England, is in Toronto at present forming a Canadian office for his firm.

W. B. STOKES, formerly of London, England, has opened a store on Notre Dame Street, Montreal, for the sale of engineering and surveying instruments. He has the sole Canadian agency for Cassella's instruments, and also for Watson's microscopes.

H. V. HUTCHINSON, of Baldry, Yearberg & Hutchinson, contractors, Westminster, London, England, is visiting Canada to determine the possibilities in this country for profitable contracts for his firm. He is making arrangements for Canadian representation.

WM. GIBBS BAIN, contracting engineer and metallurgist, of Philadelphia, is at present in Toronto. Mr. Bain was a student at the University of Toronto in the early eighties, but has resided since then in the United States. He is making a tour of the Dominion, and is particularly interested in the hydro-electric development

H. T. ROUTLY, B.A.Sc., has this summer severed his connection as engineer of the Township of Coleman, after having had charge of the highway and other engineering work during the past four years. In the course of that time the standard of high-class road construction which he set in Coleman township has been an object lesson for other and older parts of the province. Mr. Routly has established an office in Toronto.

JAMES D. ROBERTSON, formerly sales manager for the Pittsburg Valve, Foundry and Construction Company, has again assumed charge of the sales of this company, returning as second vice-president after two years' absence. Mr. Robertson in the meantime has successfully completed the organization, plant, and launching in business of the Warren Tool and Forge Company, of Warren, Ohio. He began his business career with Atwood & McCaffrey, and when that concern was absorbed by the Pittsburg Valve, Foundry and Construction Company, he continued his services, and up to the time of his withdrawal had completed his twenty-first year with the company.

In last week's "Personal" column we made mention of a trip west of Gustave Kahn, of the "Trust" Concrete Steel Company, of Canada, Limited. The Trussed Concrete Steel Company is so widely known that it seems superfluous to call attention to the typographical slip in the item as it appeared. We mention it, however, just to remind ourselves of its occurrence.

OBITUARY.

JOHN C. BAYLISS, a well-known contractor of Toronto, died at his summer residence at Dixie on August 17th. Mr. Bayliss came to Toronto some twenty years ago from Islington, England, and was engaged in contracting work in this city for the past eighteen years, his firm having built many of Toronto's public schools, the latest one being the Duke of Connaught School. The firm also built St. Anne's Anglican Church, and is at present working on the Church of St. Mary the Virgin. Mr. Bayliss also had charge of construction work in Meaford and Walkerton, Ont.

JACOB SERSON, Provincial Superintendent of Bridges for British Columbia, and a resident of Kootenay, died in Nelson, B.C., on August 12th, at sixty-nine years of age. Mr. Serson joined the construction forces of the Canadian Pacific Railway Company at Pembroke, Ont., thirty-eight years ago, when the first great transcontinental line was in its infancy. A greater part of his connection with the company was in the building of bridges throughout the West. About eight years ago Mr. Serson left the railway service to accept the position which he held with the province at the time of his death.

COMING MEETINGS.

ONTARIO MUNICIPAL ASSOCIATION.—Annual Meeting to be held in Toronto, August 28th and 29th. Secretary-treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ont.

THE NEW ENGLAND WATERWORKS ASSOCIATION.—Annual Convention to be held in Philadelphia, Pa., September 10th, 11th and 12th, 1913. Secretary, William Kent, Narragansett Pier, R.I.

THE ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Sixth General Annual Assembly will be held at Calgary, Alberta, September 15th and 16th. President, J. H. G. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Third Annual Meeting in Regina, September 18th, 19th and 20th. General Secretary, Major Lorne Drum, Ottawa; Local Secretary, R. H. Murray, C.E., Regina.

AMERICAN ROAD CONGRESS.—Annual Session will be held in Detroit, Michigan, from September 29th to October 4th. Secretary, J. E. Pennybacker, Colorado Building, Washington, D.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—Twentieth Annual Meeting to be held in Wilmington, Del., October 7th to 10th. Secretary, A. Prescott Folwell, 15 Union Square, New York.

UNITED STATES GOOD ROADS ASSOCIATION.—Convention will be held at St. Louis, Mo., November 10th to 15th. Secretary, J. A. Rountree, L021 Brown-Marx Building, Birmingham, Ala.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

19988—August 11—Authorizing the C.N.O.R., the G.T.R. and C.P.R. to operate their trains over crossing near Ottawa, Ont., without their first being brought to a stop.

19989—August 7—Authorizing the C.N.O.R. to construct its line of railway across the public road on Lot 3, Con. 5, Twp. Crerar, Ont., at station 3294.29.

19990—August 9—Authorizing the C.P.R. to construct, maintain, and operate a spur 1,490 feet in length across Richmond St., and land adjoining, in Chatham, Ont.

19991—August 8—Authorizing the C.P.R. to construct, maintain and operate a branch line of railway or spur for the Canadian Manufacturing Co., Medicine Hat, from a point on existing spur in Block "D," to and into the premises of the Can. Man. Co., in Block "D," Dunmore, Alta.

19992—August 8—Authorizing the C.P.R. to construct, maintain, and operate a branch line of railway or spur for James Murphy on Subdiv. Lots 1, 2, 3, 4, 5 and 6, Front St., and adjoining lots situate at Fort William, Ont.

19993—August 8—Authorizing the C.P.R. to construct, maintain and operate a branch line of railway or spur from a point on the south westerly limit of the Applicant Company's right-of-way, thence in an easterly direction across Lots 24, 25, 26 and 27, in the block of land lying to the north of Vine St., and westerly of Keele St., and to change the alignment of existing spur in Lots 24, 25, 26 and 28 in said block of land lying west of Keele St., West Toronto, Ont., for the Gibson, McCormack and Irvin Co., Ltd., Toronto.

19994—August 11—Approving location of the C.P.R. location of its Gimili to Riverton Branch, from a point in Sec. 17, Tp. 19, Rge. 4, E. P. M., at Gimili, Man., thence in a northerly direction to a point in Sec. 20, Tp. 23, Rge. 4, E. P. M., at Riverton, being from mileage 0.00 (at Gimili) to mileage 26.03; authorizing construction of tracks of Gimili to Riverton Branch across certain highways.

19995—August 8—Authorizing the C.P.R. to construct Bridge No. 109.4 on the Swift Current Subdiv. of its line of railway.

19996—August 12—Authorizing the C.P.R. to construct, by means of grade crossings, additional track across certain highways on its main line of railway between Percival and Broadview.

19997—August 12—Authorizing the C.P.R. to construct, by means of a grade crossing the tracks of its said ballast pit spur, at Carseland, across the highway between Secs. 5 and 6, Twp. 22, Rge. 25, W. 4 M., at mileage 0.98 of said ballast pit spur.

19998—August 13—Approving proposed change in location of C.P.R. station on Lot 3, Con. B, Twp. North Dorchester, Co. Middlesex, Ont., at Putnam.

19999—August 12—Authorizing the C.P.R. to construct road diversion in the N.W. ¼ of Sec. 7, Twp. 22, Rge. 26, W. 4 M., and to construct by means of a grade crossing the tracks of its Gleichen-Shepard Branch across diversion at mileage 24.3.

20000—August 12—Authorizing the C.P.R. to construct, maintain, and operate extensions to the existing sidings for the Dominion Government situated in Lot 20, Con. 10, Twp. of Petewawa, Co. Renfrew, Ont., at Petewawa at mileage 116.47 from Ottawa on the Applicant Co.'s Eastern Div.

20001—August 13—Approving locations of the C.P.R. stations, Portreeve and Sceptre, on its Swift Current N.W. Branch.

20002—August 11—Authorizing the Winnipeg, Selkirk and Lake Winnipeg Railway Company to construct subway at Middlechurch, to carry its Stonewall Branch underneath the West Selkirk Branch of the C.P.R.

20003—July 28—Extending the time within which the half-interlocking plant was to be constructed at Adelaide St., London, until the 15th September, 1913; and authorizing the C.P.R. to operate their cars and trains over said crossing.

20004—August 13—Authorizing the C.N.R. to construct its railway across certain highways on its Alsask Branch, Sask.

20005—August 13—Authorizing the C.P.R. to construct certain bridges on its line of railway.

20006—August 12—Approving location of the C.P.R. station at Shalketon, in the N.W. ¼ of Sec. 8, Twp. 20, Rge. 19, W. 3 M., at mileage 43.18 on its Swift Current N.W. Branch.

20007—August 13—Approving location of the C.P.R. station at Prussia, in the N.W. ¼ of Sec. 21, Twp. 22, Rge. 26, W. 3 M., at mileage 88.00, Swift Current N.W. Branch.

20008—August 13—Approving location of the C.P.R. station at Lancer in the N.Q. ¼ of Sec. 20, Twp. 21, Rge. 21, W. 3 M., at mileage 58.08, Swift Current N.W. Branch.

20009—August 11—Authorizing the G.T.P. Branch Lines Co. to divert Toronto St., between Sixth Ave. and Eighth Ave., Moose Jaw, Sask.

20010—August 11—Refusing application of the Toronto Board of Trade for a reduction of the freight classification ratings on dried fruit.

20011—August 12—Authorizing the Edmonton, Dunvegan and B.C. Ry. to construct its railway across certain highways in the Province of Alberta.

20012—August 8—Authorizing the New Brunswick Coal and Railway Co. to construct bridge No. 33.4 at Cumberland Bay, N.B.

20013—August 9—Authorizing the Edmonton Interurban Railway Co. to operate its cars over the crossing of the tracks of the E. D. and B. C. Ry., (pending the installation of an interlocking plant), for construction purposes only.

20014—August 12—Authorizing the G.T.R. to construct, maintain and operate a branch line of railway, or siding, commencing at a point on its railway on Lot No. 262, Subdiv. Lot 102, Lachine, Que., thence extending northerly to and into the premises occupied by the Railway Signal Co., on subdiv. Lots 103, 104, 105, 106 and 107 of Lot 262, in the city of Lachine.

20015—August 9—Ordering the G.T.R. to construct a subway twenty-four feet wide on Bay Street, village of Callender, Ont.

20016—August 12—Approving location of G.T.P. Branch Lines station at Gorlitz, Sec. 25, Tp. 28, Rge. 24, W. 2 M., mileage 43.3 on its Yorkton Extension.

20017—August 11—Ordering the C.P.R. to install an improved type of illuminated electric bell, within ninety days from this Order, at the Main St. crossing in the village of Shelburne, Ont.

20018—August 14—Amending Order No. 18705 by providing that the cost of the maintenance of the watchman at Anderson St. crossing, west of station building at Grenfell, Sask., be divided equally between the C.P.R. and the municipality.

20019—August 15—Approving location of C.P.R. proposed station on road allowance between Secs. 8 and 9, Twp. 13, Rge. 12, W. 4 M., at Ronolane, Alta., at mileage 22.5, Suffield to Blackie Branch.

20020—August 13—Approving portion of location of C.P.R. Snowflake westerly branch from mile 0, a point in Sec. 18, Tp. 1, Rge. 9, W. P. M., thence in a westerly direction to a point in Sec. 14, Tp. 1, Rge. 11, W. P. M., at mile 9.10.

20021—August 13—Authorizing the Toronto, Hamilton and Buffalo Ry. to construct and maintain bridge across the Welland River at Coyle, Ont.

(Continued on Page 86.)

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

RAILWAYS—STEAM AND ELECTRIC.

Ottawa, Ont.—Tenders will be received up till the 8th of September, 1913, for the double tracking of the line between St. Romuald and Chaudiere curve. Plans and specifications may be obtained from the Chief Engineers's office, Moncton and the Department of Railways and Canals. L. K. Jones, Deputy Minister and secretary.

Sussex, N.B.—Tenders will be received up till the 3rd of September, 1913, for the construction of a passenger station. Plans and specifications may be obtained from Chief Engineer, Moncton, N.B. and the Department of Railways and Canals. L. K. Jones, Deputy Minister and secretary.

BRIDGES, ROADS AND PAVEMENTS.

Barrie, Ont.—MESSRS. CURRAN & CLEMENT, Orillia, Ont., have been awarded the contract for paving work.

Calgary, Alta.—In anticipation that the deal for an extra million dollars offered by Stimson and Company, of Toronto, to the city, will be negotiated, plans for enlarging on the paving programme of the city for this season are being laid in order to be ready to go ahead with the work without losing any time when the money is assured.

▲—Cayuga, Ont.—Tenders will be received up till the 16th of September, 1913, for the construction of 26½ miles of stone macadam road. Plans and specifications may be obtained from T. A. Snyder, County Clerk,

▲—Kingston, Ont.—Tenders will be received up till the 5th of September, 1913, for the construction of 4,250 square yards of asphalt block pavement, 1,330 lineal feet of concrete curb and gutter, 1,040 lineal feet of cement gutter and 2,000 square feet of cement walks. Plans and specifications may be obtained from R. J. McCallum, City Engineer.

▲—London, Ont.—Tenders will be received up till the 11th of September, 1913, for the supply and erection of three 130 feet spans riveted truss steel highway bridges over the Thames River. Plans and specifications may be obtained from Wm. N. Ashplant, City Engineer.

+—London, Ont.—The City Council has awarded MESSRS. FOLEY AND GLEESON the contract for the construction of 1,900 feet of sheet asphalt paving, including curbs and gutters. The contract price is $12,240.

London, Ont.—New cement walks will be laid on Bathurst Street from Waterloo to Colborne, and also on York from Wellington to Colborne. Tenders will be called for shortly.

London, Ont.—Tenders will be called shortly for the construction of 1⅛ mile of asphaltic concrete paving. W. N. Ashplant, City Engineer.

+—Montreal, Que.—MESSRS. QUINLAN & ROBERTSON have been awarded the contract for laying of granite blocks on Cote St. Paul Road at $1.80 per square yard. The blocks are to be supplied by the city.

+—Montreal, Que.—The City Council has awarded the SICILY ASPHALTUM COMPANY the contract for the construction of a special pavement with a wearing surface of 2 inches on two streets. The contract prices were for the first street, $2.91 per square yard or $9,079.20 for the whole, and for the second, $2.79 per square yard or $3,878.12 for the whole.

+—Montreal, Que.—The City Council has awarded the CANADA CREOSOTING COMPANY Ltd., the contract for resurfacing with wooden blocks St. Sulpice and Bonsecours Streets. The contract price was $3.09 per square yard.

+—Peterborough, Ont.—The Board of Works has awarded MESSRS. FOLEY AND GLEESON the contract for the paving of George Street. The tenders for the work were as follows:—Warren Bituminous Paving Company.—Bitulithic and stone blocks, $73,082.50; bitulithic and paving blocks, $71,188.43; asphaltic concrete and stone blocks, $65,785.22; asphaltic concrete and paving blocks, $63,810.62. Foley and Gleeson.—Asphaltic concrete, $63,827.57; asphaltic concrete and paving blocks, $63,810.62. If the bitulithic pavement

Tarvia

Preserves Roads
Prevents Dust~

Atwater Avenue, Montreal, Quebec. Constructed with Tarvia Modern Pavement.

Fifty Million Yards Treated

THE rear wheels of an automobile revolve more times to a mile than the front ones do.

There is a certain amount of slip when the car is driven at high speed, and this slip exerts upon the road surfaces a powerful and destructive abrasive effect exactly like that of an emery wheel.

Ordinary macadam never was expected to withstand such strains and soon goes to pieces unless it is given constant and costly care.

A macadam road, to meet the demands of modern traffic, requires the use of an additional binder to reinforce the surface. Tarvia is ideal for this purpose and has been used successfully on over 50,000,000 yards of roadways and pavements.

Tarvia may be applied to the road during construction or merely as a surface application.

There is such a vast economy in maintenance expense that it more than balances the cost of the Tarvia treatment.

Tarvia is made in three grades—"Tarvia X," very heavy and dense for road construction where the voids are large; "Tarvia A," a lighter grade for the smaller voids which occur in surface operations; "Tarvia B," applied cold for dust suppression and surface maintenance.

THE CARRITTE-PATERSON MANUFACTURING CO., LIMITED
ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

had been decided upon, it would have cost the city between $9,000 and $10,000 more than it is costing for the asphaltic pavement, and according to City Engineer Parsons, as good a material is being obtained for that much less money. The asphaltic pavement has been guaranteed for a term of five years by Messrs. Foley and Gleeson, with the Bond Company, and if the board are willing to accept a personal bond, they will guarantee it for a further five years.

Peterborough, Ont.—Toronto firms have tendered for paving work here as follows:—From the Warner Paving Company, Toronto.—For bitulithic pavement, $2.46 per square yard; asphaltic concrete, $2.14 per square yard; stone block, $4.28 per square yard; brick, $3.25 per square yard; straight concrete curb, 28 cents per lineal foot; curved concrete curb, with Wainwright steel bars, 82 cents per lineal foot; curved concrete curb, without bar, 32 cents per lineal foot; concrete gutter, 27 cents per square foot; concrete sidewalk, 15½ cents square foot; headers, 38 cents per lineal foot. From Clark and Monds, Toronto.—For concrete pavement, $1.28 per square yard; for concrete straight and curved curb, 30 cents per lineal foot; concrete gutter, 15 cents per square foot.

Regina, Sask.—Some of the wholesale houses in the civic wholesale section at Regina have decided to have reinforced concrete roads lead into their premises from the city streets. The Cockshutt Plow Company and the H. G. Smith Company, Limited, have decided to have such roadways built.

+—St. Amicet, Que.—MESSRS. ROUTLEY & SUMMERS, Toronto and Haileybury, Ont., have been awarded the contract for 13½ miles of macadam roadway.

Vernon, B.C.—Mr. Hamilton Long, road superintendent of the Okanagan electoral district, estimates that it will cost $1,026,000 to standardize the roads of the Okanagan and to convert a hundred miles of trail into the wagon roads that the rapid development of the district will make imperative in the near future.

Victoria, B.C.—An arrangement has been arrived at with the Canadian Mineral Rubber Company, which will permit the immediate commencement of operations on the paving of the Gorge Road between Douglas Street and Manchester Road. This work has been delayed for some time. Payment will be made from general revenue, to be returned out of the usual local improvement assessments when these can be levied.

Victoria, B.C.—Final action has been taken by the municipal Council of Saanich in regard to the paving problem. The council authorize the Worswick Paving Company and Warren Brothers to do the work.

Welland, Ont.—Tenders will be received up till August 26th, 1913, for the construction of a thirty-foot concrete arch bridge over Lyons Creek, on the Town Line Road, between the Townships of Humberstone and Crowland. Plans and specifications may be obtained from George Ross, County Engineer, Welland, Ontario.

LIGHT, HEAT AND POWER.

Calgary, Alta.—Tenders will be received up till the 3rd of September, 1913, for supplying 75 luminous arc lamps standards. Plans and specifications may be obtained from J. M. Miller, City Clerk.

+—Montreal, Que.—The City Council has awarded Mr. G. M. GUEST the contract for the laying of underground wire conduits on St. Catherine Street and in Park Avenue and Bleury Street. The contract price is, for the first-named street, $45,969 and the second-named, $128,000. The Bell Telephone will pay $10,496 towards the work on Bleury Street.

+—Montreal, Que.—The City Council has awarded the SAYER ELECTRIC COMPANY the contract for the electric lighting of Bonsecours Market. The contract price is $2,542.

Regina, Sask.—The new 1,500 k.w. unit, for the power house, ordered from Quillans and Robertson, of Birmingham, England, has arrived. The boilers which have also arrived were purchased from the Babcock-Wilcox Company. Each boiler has a capacity of 500 horse-power and a pressure of 200 pounds.

▲—Regina, Sask.—Tenders will be received up till the 1st of October, 1913, for supplying power-house equipment. Plans and specifications may be obtained from E. W. Bull, Superintendent of Light and Power Commission.

Saskatoon, Sask.—Following upon the discussion in Prince Albert regarding the power scheme undertaken there, at a public meeting the announcement was given out that during the winter the flow of water would be more than was counted upon. City Commissioner Yoarth made a statement regarding the question of river power at Saskatoon. He stated that from data he possessed, a flow of only 1,382 cubic feet of water per second could be counted upon, whereas in previous estimates of power schemes 3,000 had been the amount considered possible. He considers that it is impracticable to generate power from the South Saskatchewan River sufficient for the requirements of Saskatoon, but believes that it is worth an investigation to inquire into the possibilities of a power development scheme at the junction of the north and south branches.

Victoria, B.C.—A basis for the lighting of Saanich municipality at a cost of $27,000 for installation was submitted to the municipal council recently by the British Columbia Electric Railway Company, and laid over for consideration by the works committee. Two constant current regulators with switchboard complete, with a capacity of 500 of 80 watt lamps, or 450 of 94.4 watt lamps, were proposed, and a map attached to the report suggested 250 locations, with 200 to be added later. Payment was proposed to be spread over five years with interest at 6 per cent. on unpaid amounts. The municipality was to provide suitable accommodation for the housing of regulators, and to arrange for turning on and off the lights. The rate for current was set at 3½ cents per k.w.h., with a minimum of 500, or 3 cents per k.w.h., with a minimum of 1,000. Lamps and renewals were to be a charge on the municipality.

+—Winnipeg, Man.—The Winnipeg Electric Railway Company, a Mackenzie-Mann enterprise, are up against a big problem in connection with their present power plant at Lac Du Bonnet on the Winnipeg River, forty miles east of the city. After it was first put in, at a cost of millions, the company three years ago found it necessary to spend another large sum in blasting to secure a greater flow over the falls. Still it is not sufficient and frequently the company has to fall back on its auxiliary steam plant to supply its demands. Ice in the spring and fall is also a big drawback. It is now announced that the company will build another big plant twelve miles farther down the river towards Lake Winnipeg. The new site is forty-five miles from Point du Bois, the civic plant's location. J. G. WHITE AND COMPANY, New York contractors, have been awarded the contract for the construction of the plant, which will cost four or five millions. The location is Grand Bonnett Falls. Two falls will be blown out. It is not thought it will effect detrimentally the civic plant.

Winnipeg, Man.—Tenders will be received up till the 20th of September, 1913, for the supply of labor and materials necessary for or incidental to the erection of a duplicate transmission system. Plans and specifications may be obtained from the Board of Control. M. Peterson, secretary.

GARBAGE, SEWAGE AND WATER.

Calgary, Alta.—Dr. Mahood, city health officer, has received the report from the provincial analyst on the monthly test of the Calgary city water. Samples were taken from both the chlorinated supply from the Bow and the untreated supply from the Elbow. The report shows that both samples were very low in nitrates, nitrites and free ammonia, and absolutely free from colon bacilli.

Chelsea, Ont.—At a meeting of Chesley Council it was decided to buy an oil engine for the waterworks plant. Apparently the gas producer has seen its best days, and it is the council's intention to repair the old producer and use it as an auxiliary plant.

Edmonton, Alta.—City Engineer Latornell has submitted a report to the Commissioners of the proposed sewage purification works to be erected on Ross flats. An appropriation of $30,000 was made in 1912 for this work.

Montreal, Que.—At a recent meeting of the Board of Control, the filter contract matter was settled. Mr. Norman M. McLeod, the contractor is given an extension of time for fifteen months. The city agrees to remit the fine of $100 a day, beginning with September 1, for the non-finishing of

the work by that date, and not to impose it till December 1, 1914. Mr. J. W. McConnell, financial broker, gives his joint guarantee with Mr. McLeod for the finishing of the work. Twelve thousand dollars are advanced to Mr. McLeod. He assumes responsibility for the damages caused by the frosts of last winter. The contractor agrees to forfeit one hundred dollars a day if the works are abandoned till they are finished.

Newmarket, Ont.—The town of Newmarket is extending its water supply by artesian wells, which are being done by Mr. Harvey. The work will be started shortly.

Regina, Sask.—Ten machines are employed in Regina laying mains for sewer and water. Three and one-half miles of sewers were laid during the month of July and six acres of paving.

Toronto, Ont.—The J. H. McKNIGHT CONSTRUCTION CO. were awarded the contract for the Balsam Avenue sewer. Their tender to do the work for the sum of $45,900 was accepted a few days ago.

+—Toronto, Ont.—The contract has been awarded to MORAN & CO., Ottawa, for the construction of one of the large western outlets of the trunk sewer, the price being $89,416.

+—Toronto, Ont.—MESSRS. DONNELLY, GRAHAM & GEROW, of Cleveland, Ohio, have been awarded the contract for the construction of 5,800 feet of sewer on Woodville Avenue. The course of the tunnelling runs through sand, clay and quicksand requiring the use of compressed air and extreme care in construction. The contract price amounts to $63 a foot.

+—Toronto, Ont.—The following contracts for sewers have just been let by the city. One for Woodville Avenue, West Toronto, amounts to $366,000. The others are as follows: Balsam Avenue, Queen Street to Kingston Road, $45,900; Carlaw Avenue, storm overflow, $28,580; outlet at East Toronto, $86,000; Earlscourt drainage system, $45,838; Midway outlet, $89,416.

▲—Toronto, Ont.—Tenders will be received up till the 2nd of September, 1913, for the construction of a number of sewers. Plans and specifications may be obtained from the Board of Control. H. C. Hocken, chairman.

Winnipeg, Man.—Consulting Engineers F. P. Stearns, Rudolph Hering and James A. Fuertes, of New York, have submitted their report upon the proposal to use Shoal Lake as the source of water supply for the Greater Winnipeg water district. The report was considered by the Mayor and controllers immediately on receipt. It is favorable to the project and recommends that the work be undertaken with as little delay as possible. It states that the cost at which the water can be brought to Winnipeg is a very moderate one and they estimate that it would be lower than had been expected. No treatment of the water will be necessary at any part of the year.

INDUSTRIAL WORKS.

+—Calgary, Alta.—The City Council has awarded the GENERAL SUPPLIES COMPANY, a local concern, the contract for supplying valves and steam pipes. The contract price was $26,000, $900 less than the tender, and in the event that the pipe is delivered in the time specified the company be given a bonus of the remainder of the amount of the tender, or $900, the idea being to hold back the $900 as a penalty against delay. The motion further provided that if the general supplies declined to accept the action of the council, the contract go to the Pittsburg Valve Company.

Canoe, B.C.—Tenders will be received up till the 11th of September, 1913, for the construction of a public wharf. Plans and specifications may be obtained from F. W. Aylmer, District Engineer, Chase, B.C.; J. S. McLachlan, District Engineer, Victoria; and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

+—Fort William, Ont.—The THUNDER BAY CONTRACTING CO. have been awarded the contract for a new pump house. The contract price is $12,995.

Gillies Bay, B.C.—Tenders will be received up till the 15th of September, 1913, for the construction of a wharf at Shelter Point. Plans and specifications may be obtained from C. C. Worsfield, District Engineer, New Westminster and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Laprairie, Que.—Tenders will be received up till the 23rd of September, 1913, for the construction of a protection dyke. Plans and specifications may be obtained from District Engineers, J. L. Micnaud, Montreal, Charles Chapais, Quebec and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Main Duck Island, Ont.—Tenders will be received up till the 16th of Septembr, 1913, for the construction of a reinforced concrete tower, wooden dwelling, boathouse and oil store. Plans and specifications may be obtained from the Department of Marine and Fisheries, Ottawa. Alex Johnson, Deputy Minister.

Montreal, Que.—Tenders will be received up till the 4th of September, 1913, for supplying the office fittings and furniture for the central post-office. Plans and specifications may be obtained from Mr. R. L. Deschamps, Montreal and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Montreal, Que.—Tenders will be received up till the 8th of September, 1913, for the alterations and additions to fittings for postal station "B." Plans and specifications may be obtained from Mr. R. L. Deschamps, Montreal and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

▲—Neepawa, Man.—Tenders will be received up till the 1st of September, 1913, for supplying machinery for additions to the power plant. Plans and specifications may be obtained from *The Canadian Engineer's* offices at Winnipeg, Toronto, and Montreal; W. E. Skinner, Limited, Consulting Engineers, Winnipeg, and J. W. Bradley, Secretary-Treasurer.

▲—Ottawa, Ont.—Sketch designs in a preliminary competition for the erection of departments and courts buildings, will be received up till the 2nd of January, 1914. Conditions for both competitions may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Ottawa, Ont.—Tenders will be received up till the 4th of September, 1913, for timber on the Dokis Reserve. Plans and specifications may be obtained from the Department of Indian Affairs, Ottawa. J. D. McLean, secretary.

Ottawa, Ont.—Tenders will be called for shortly for the largest of Canadian ice-breakers. The vote was granted last session, and the plans since under preparation by Naval Architect Duguid, of the Marine Department, are nearing completion. The ship will operate between Montreal and Quebec to facilitate the early opening of navigation in conjunction with the Montcalm and the Lady Grey. It will be 275 feet long, 57 feet wide, 32 feet deep, and will have a draught of 20 feet and 9,000 indicated horse-power.

Regina, Sask.—The Gutta Percha Rubber Company, have through their manager, Mr. Candee, signified their intention of establishing a branch of the business at Regina. The city has been requested to reserve the spur track sites in the city warehouse section, where it is proposed to erect the building.

+—Saskatoon, Sask.—The City Council has awarded the H. G. BAKER COMPANY, Ltd., the contract for supplying the public schools with wood for the winter at $5.95 delivered. J. H. STEWART COMPANY was awarded the contract for the coal at $9.40 per ton, or 30 cents a ton more than last year.

+—Saskatoon, Sask.—The school board has awarded the CHARETTE KIRK COMPANY, Winnipeg, the contract for the plumbing, heating and ventilating of the Buena Vista school. The tenders were as follows:—Cotta Brothers, Winnipeg, $35,214; James Brandon, Saskatoon, $29,625; General Fire Extinguisher Company, Montreal, $26,039; Charette Kirk Company, Winnipeg, $24,900.

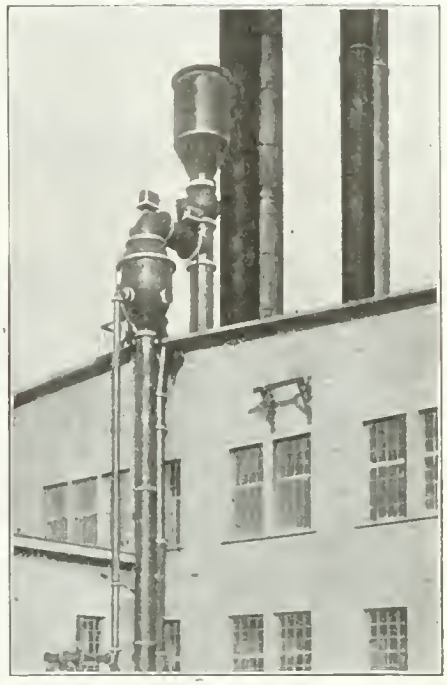
Toronto, Ont.—Three firms, one in Montreal, one in Pittsburgh, and the third in New York, will tender jointly for the big contract in connection with the projected improvements of Toronto Harbor. The tender will be presented under the name of the Montreal company. The companies are:—Messrs. Lauren and Leach, Montreal; Booth and Flynn, Pittsburg; and T. A. Gillespie and Company, New York. For some weeks engineers representing these firms have been in the city gathering information and recently the principals arrived to further negotiations.

+—Vancouver, B.C.—The Dominion Government has awarded HENRY McFEE AND McDONALD the contract

CONDENSING APPARATUS

specially designed to secure

GREATER STEAM ECONOMY



WORKS: WILLIAM and SEIGNEURS STREETS, MONTREAL

THE JOHN McDOUGALL CALEDONIAN IRON WORKS CO., Limited

Manufacturers of Boilers, Castings, Condensers, Elevators, Engines, Filters, Forgings, Hydraulic Machinery, Pumps, centrifugal and reciprocating, Steam Turbines, Tanks, Water Wheels, Water Works Plants.

The Hampton Sedimentation Tank

Used in connection with an electrolytic hypochlorite treatment, the process is **ABSOLUTELY ODORLESS** and the effluent is free from disease germs.

Nine years of operation in large and important installations in England have demonstrated that an effluent exceptionally low in suspended solids and as free from odor as the entering sewage may be obtained with The Hampton Tank.

The Hampton Tank reduces the cost of any subsequent treatment.

Write for leaflet showing construction of the tank and explaining the special features of its design which make it particularly successful. This tank is not an experiment. It has been used for nine years with most satisfactory results, and has **PROVED** its efficiency and economy.

Leaflet on request.

Sterilization Co.

Union Building, Clinton Street

NEWARK, N.J.

Also engineers for the electrolytic treatment of water.

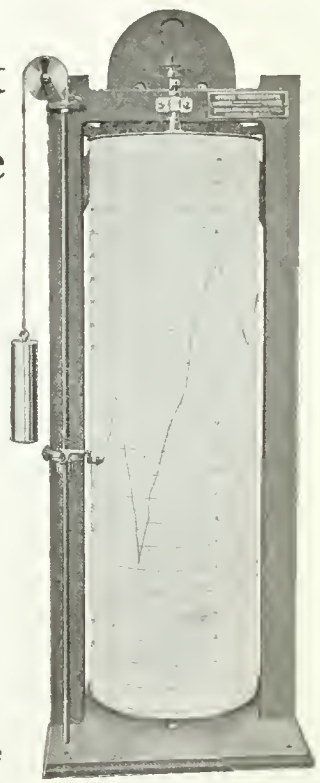
A Perfect Weir Gage

Carries an unusually large card and will register without any reduction through a variation of two feet or on a two to one reduction through a variation of four feet.

Can be applied anywhere where fluctuation is within limit named and where great accuracy is desired.

In use on weirs, sewage disposal plants, irrigation and stream gaging.

Write for Catalogue



Hydro Chronograph Weir Gage.

Hydro Manufacturing Co.

700 BULLITT BUILDING, PHILADELPHIA, Pa.

for the construction of a wharf to handle the largest ocean steamers. The contract price is $1,250,000.

Yarmouth, N.S.—Tenders will be received up till the 4th of September, 1913, for dredging required here. Plans and specifications may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

+—Yorkton, Sask.—MESSRS. LOGAN & BLACK, of Yorkton, Sask., have been awarded the contract for the construction of a new telephone building. Parrott & Byers, Yorkton, Sask., have been awarded the contract for the plumbing of the building.

MISCELLANEOUS.

Alexandria, Ont.—Tenders will be received up till the 2nd of September, 1913, for the construction of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence, Ottawa. Eugene Fiset, Deputy Minister.

Athabasca, Alta.—The town council have decided to erect a new town hall.

Chilliwack, B.C.—Tenders will be received up till September 8th, 1913, for the erection of a frame school building. Plans and specifications may be seen at the offices of the Inspectors of Indian Agencies at Vancouver and Victoria, the Indian Agent, New Westminster, and the postoffices at Chilliwack and Nelson. J. D. McLean, Assistant Deputy and Secretary.

+—Cobalt, Ont.—The Town Council has awarded MESSRS. HILL-CLARK-FRANCIS Ltd., New Liskeard, the contract for the erection of the mnnicipal buildings.

+—Fort William, Ont.—Mr. P. J. DOURHUE has been awarded the contract for the erection of the Fort William car barns. The contract price is $34,600. Mr. JAS. TONKIN was awarded the contract for the excavation.

+—Fort William, Ont.—The Fife Hardware Company has awarded Mr. A. C. STEWART the contract for the erection of a wholesale warehouse. The contract price is $40,000.

+—Indian Head, Sask.—The Dominion Government has awarded JAMES McDIARMID AND COMPANY, Winnipeg, the contract for the erection of a drill hall. The contract price is $13,700.

+—Lethbridge, Alta.—The contract was let this week by Industrials Limited, for the construction of a $7,000 macaroni factory on the city industrial site off 13th Street. The contract went to a Blairmore builder and thus the first home industry under the city's new $6,000 commissioner disburses this local capital among outsiders.

+—Medicine Hat, Alta.—The Salvation Army has awarded MESSRS. SACKRIDGE AND TURNER, local contractors, the contract for the erection of a citadel. The contract price is $20,000.

Merritt, B.C.—Tenders will be received up till September 11th, 1913, for the construction of a new drill hall. Plans and specifications may be obtained from the offices of the District Officer Commanding the Military District No. 11, Victoria, B.C.; the Town Clerk, Merritt, B.C., and the Director General of Engineer Services, Headquarters, Ottawa. Eugene Fiset, Deputy-Minister, Ottawa, Ont.

Montreal, Que.—Tenders will be received up till the 2nd of September, 1913, for renewing roofs of boilerhouses and pump-house. Plans and specifications may be obtained from the Board of Commissioners. L. N. Senecal, secretary.

New Westminster, B.C.—The city council are considering the expenditure of $2,000,000 on a new Union depot.

+—Port Arthur, Ont.—The Molsons Bank has awarded MESSRS. SEAMEN AND PENNIMEN the contract for the reconstruction of their new building.

Regina, Sask.—The W. G. Downing, Limited, has had plans prepared of a factory to cost $50,000, the erection of which will be commenced as soon as tenders have been received. Storey and VanEgmond, architects, of Regina, have charge of the plans. The building will be four stories in height, and of the ground dimensions of 50 feet by 113 feet. It will be of brick construction.

Regina, Sask.—The tender of the R. J. LECKY CO. for the construction of the new wing of the Regina General Hospital, has been accepted by the Hospital Board. The contract price is $88,107.

Regina, Sask.—The contract for the erection of the isolation hospital has been let to MINKLEY & TRAUB, their tender for the work being $77,600.

Rosetown, Sask.—Tenders will be received up till September 1st, 1913, for the erection of a building. Plans and specifications may be obtained from Builders' Exchange, Moose Jaw, Regina and Saskatoon. C. E. Coulin, Mayor.

Saskatoon, Sask.—The City Health Department is compelling contractors to keep all excavations free from stagnant water, such water having in several cases became exceedingly offensive and consequently undesirable. After each rain, contractors are now compelled to pump out all such excavations.

Sault Ste. Marie, Ont.—A new $60,000 coal unloader, of double tramway type, one of the most up-to-date in Canada, and only recently completed, was completely demolished by windstorms on August 21st.

+—Sudbury, Ont.—MESSRS. DORAN AND DEVLIN, Ottawa, have been awarded the contract for a public building. The contract price is $98,200.

+—Toronto, Ont.—MR. W. R. PERRIN, consulting architect and engineer of the civic abattoir, has been awarded the contract for supplying the interior fittings and machinery. The contract price is $108,376.

+—Vancouver, B.C.—The Alaska Bedding Company has awarded Mr. F. T. SHERBORNE the contract for the erection of a four-story factory. The contract price is $30,000.

+—Vancouver, B.C.—Mr. R. J. McLean has awarded the DOMINION CONSTRUCTION COMPANY the contract for the erection of the new Commercial Drive Theatre. The contract price is $30,000.

Vanguard, Sask.—Mr. Duckett, of the Sask. Co-operative Elevator Company, Ltd., has been in Vanguard for the last few days arranging the final details of the organization to enable the company to establish their new 30,000 bushel elevator at this point. The company tried to negotiate the purchase of one of the existing elevators but failed to put through a deal, and as the necessary capital has been subscribed by the farmers the company will build an entirely new elevator.

Victoria, B.C.—Tenders will be received up till the 9th of September, 1913, for the erection of the Robson school. Plans and specifications may be obtained from the Department of Pubic Works, Victoria. J. E. Griffith, Public Works Engineer.

Victoria, B.C.—Tenders will be received up till the 10th of September, 1913, for the erection of the Salmo lock-up. Plans and specifications may be obtained from the Department of Public Works, Victoria. J. E. Griffiths, Public Works Engineer.

+—Winnipeg, Man.—The Dominion Government has awarded MESSRS. RUTHERFORD AND BONOGH the contract for the erection of a fish hatchery in Lake Winnipeg. The contract price is $11,000.

+—Winnipeg, Man.—Mr. D. H. Beadley has awarded the WINNIPEG STONE COMPANY the contract for the erection of an apartment block. The contract price is $65,000.

CURRENT NEWS.

Montreal, Que.—The Raymond Concrete Pile Company, whose chief offices in Canada are in the New Birks Building, Montreal, have opened a branch office at Buffalo, N.Y., in the Ellicott Square Building, in charge of Mr. Edward Phelan.

Vancouver, B.C.—By virtue of an agreement signed in Victoria recently by William Young, Provincial Controller of Water Rights, representing the Provincial Government, and J. B. Challies, chief engineer of the Hydrographic Survey Branch of the Interior Department, Ottawa, representing the Dominion Government, the latter government agrees to extend the hydrographic work now in progress in the Dominion railway belt to all other districts of British Columbia. Dominion Government water rights in the Canadian Pacific Railway belt in British Columbia has been transferred to the Provincial Government, which gives local jurisdiction over every important water power plant and scheme adjacent to Vancouver and Kamloops.

Triple Expansion Pumping Engine

FOR WATER WORKS, MINE SERVICE, ETC.

THE Fairbanks-Morse Triple Expansion Duplex Outside Centre Packed Plunger Pumping Engine shown here is very economical in the consumption of steam. The economy of operation makes this Pump preferable to all others in many situations.

¶ The steam end is fitted with semi-rotative valves. The plungers being externally packed are always in sight and any leakage can be at once detected. All parts are easy of access. The stuffing boxes are large and deep, so that an ample allowance of packing may be used.

¶ This type of pump is heavily proportioned throughout in order to meet the demands of heavy service. It is designed to give long and satisfactory service at a minimum cost. It has a 24-inch stroke and a capacity of 2,500,000 gallons per 24 hours.

Complete detail specification sent on request. *Address our nearest Branch.*

NOTICE TO CONTRACTORS.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, up to noon on Tuesday, September 2nd, 1913, for the construction of the following sewers:—

Turner Road, from Davenport Road to Tyrell Avenue.

Kingston Road, from Main Street to Victoria Park Avenue.

Conrad Avenue, from Hillcrest Drive to Tyrell Avenue.

Orchard Park Avenue, from Queen Street to North End.

Frichot Street, from Yonge Street to E. S. McMurrich St.

Frank Crescent, from Hillcrest Drive to Bracondale Hill Road.

Hillcrest Drive, from Christie Street to Tyrell Avenue.

St. Mathias Place, from Claremont Street to Bellwoods Avenue.

Lane 1st N. Bloor Street, from Euclid Avenue to Manning Avenue.

Lane 1st S. Adelaide Street, from Charlotte Street, to Lane 1st W. Peter Street.

Lane 1st S. Humberside Avenue, from Keele Street, to 144′ East.

Lane 1st W. Euclid Avenue, from Lane 1st N. Bloor Street to London Street.

Lane 1st N. King Street, from Charlotte Street to East End.

Lane 1st W. Sherbourne Street, from Duchess Street to 142′ Sonth.

Lane 1st N. St. James Avenue, from Rose Avenue to Parliament Street.

Midway Drainage System, viz. Felstead, Lamb and Danforth Avenues.

Divisions No. 1 and 2, West Toronto, Bloor Street.

Lane 1st W. Peter Street, from Adelaide Street to Lane 1st N. of King Street.

Lane 1st W. Berkeley Street, from Lane 1st N. Wilton to Lane 1st S. Gerrard St.

Envelopes containing tenders must be plainly marked on the ontside as to contents.

Specifications may be seen and forms of tender obtained at the office of the Commissioner of Works, Toronto.

Tenders shall submit with their tender, the names of two sureties (approved of by the City Treasurer, not members of the City Council, or officers of the Corporation of the City of Toronto), or in lieu of said sureties, the bond of a Guarantee Company approved of as aforesaid.

The usual conditions relating to tendering as prescribed by the City By-law must be strictly complied with.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN, (Mayor),
Chairman, Board of Control.

Toronto, August 20th, 1913.

CITY OF KINGSTON.

TENDERS FOR PAVEMENT.

Sealed tenders will be received by the undersigned up to 3 o'clock p.m., Friday, September 5th, 1913, for the construction of approximately 4,250 square yards of asphalt block pavement, 1,330 lineal feet of concrete curb and gutter, 1,040 lineal feet of concrete gutter and 2,000 square feet of concrete walk (widening walk).

Plans and specifications may be seen and all other information obtained at the office of the undersigned.

A marked cheque for five per cent. of the amount of the tender must accompany each bid.

The lowest or any tender not necessarily accepted.

R. J. McCLELLAND,
City Engineer.

City Buildings,
Kingston, Ont., August 26th, 1913.

CITY OF LONDON.

TENDERS FOR STEELWORK.

Sealed proposals addressed to the Chairman and Members No. 2 Committee will be received at the office of the City Clerk up to 5 p.m. on Thursday, 11th day of September, 1913, for the supply and erection of three 130 feet spans rivetted truss steel highway bridge over the River Thames, the substructure for which is already under construction.

Plans, specifications and all particulars can be had at the office of the City Engineer.

No tenders will be considered unless accompanied by a deposit cheque for 5 per cent. amount of the bid.

The lowest or any tender not necessarily accepted.

B. W. BENNETT, Chairman No. 2 Committee. Wm. N. ASHPLANT, City Engineer.

PROPOSED GOVERNMENT BUILDINGS, OTTAWA, ONT.

Architects are invited to submit sketch designs in a preliminary competition for the erection of departmental and courts buildings.

From the designs submitted in this preliminary competition, six will be chosen by the Assessors, the authors of which will be invited to submit more matured designs in a final competition, for which the five unsuccessful competitors shall each receive an honorarium of three thousand dollars ($3,000).

The author of the design placed first by the Assessors will be entrusted with the work which the Government intends carrying ont at once.

The competition is limited to British subjects practising in the British empire.

The Government has appointed Mr. T. E. Collcut, Mr. J H. G. Russell and Mr. J. O. Marchand, as Assessors to act in its behalf.

The designs in the first competition must be delivered in Ottawa (carriage paid) not later than 12 o'clock noon, 2nd January, 1914, addressed to the undersigned.

Conditions for both competitions may be had on application to the undersigned, and at the office of the High Commissioner for Canada, 17 Victoria Street, London, England.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, August 18, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—44890.

When designing

structures do you pay sufficient attention to the various matters that govern insurance ratings?

Not only can you add greatly to the fireproofness of buildings by adopting our suggestions, but it is very likely that you can do so without the improvements costing anything ultimately. They will be paid for by the lower insurance rates.

Correspondence solicited. We have a staff of engineers and inspectors trained in this highly specialized line. Make use of our services.

In making sewer pipe

many pieces come from the kilns with imperfections. They are rendered imperfect by having pieces broken out of the socket or spigot end, or having fire cracks at either end or extending partly through the body of the pipe. Or they may be imperfect in shape, out of round or not straight; not thoroughly vitrified or glazed; or with blisters or scales blown off the outside. Such pieces cannot be classed as strictly first-class pipe. When buying pipe from us one can rest assured that we will never deliver pipe with imperfections such as above unless "seconds" are particularly asked for by the purchaser.

Building Stones and Clay Products.

A Handbook for Architects.

By HEINRICH RIES, Ph.D., Professor of Economic Geology, Cornell University. 8vo, xiii+415 pages, 59 plates, including full-page half-tones and maps. 20 figures in the text. Cloth, $3.00 net.

Gives the fundamentally important facts and takes up the more important occurrences of building stone. The author has also included a list of structures in which the more important building stones have been placed.

Practical Methods of Sewage Disposal

For Residences, Hotels and Institutions.

By HENRY N. OGDEN, M. Am. Soc. C.E., Professor of Sanitary Engineering, Cornell University, and H. BURDETT CLEVELAND, Assoc. M. Am. Soc. C.E., Principal Assistant Engineer, New York State Department of Health. 8vo, vi + 132 pages, 52 figures. Cloth, $1.50 net.

Contains tables for use in constructing the different types of plants, together with the necessary plans, sections, views, etc.

SECOND EDITION, Rewritten and Enlarged

Engineering for Land Drainage.

By CHARLES GLEASON ELLIOTT, C.E. 12mo, xvi+339 pages, 60 figures. Cloth, $2.00.

A manual for the reclamation of lands injured by water.

Applied Methods of Scientific Management.

By FREDERIC A. PARKHURST, M.E., Assoc. Am. Soc. M.E. 8vo, xii + 325 pages, 48 figures and 9 plates. Cloth, $2 00 net.

This book will appeal strongly to the manager or superintendent of a plant, as it contains valuable suggestions and outlines the routine which should be assigned to almost every employee.

Gas Power.

By Professor C. F. HIRSHFELD, M.M.E., and T. C. ULBRICHT, M.M.E., Cornell University. Small 8vo, viii+198 pages, 60 figures. Cloth, $1.25 net.

Gives the reader such knowledge of the methods and facts of gas power as may enable him to appreciate the present commercial status of this branch of engineering.

Tenders Called For

CAYUGA, ONT.

Sealed tenders will be received up to noon on the 16th day of September, 1913, by the undersigned at Cayuga, Ontario, for the construction of twenty-six and one-half miles of stone macadam road in the county of Haldimand.

The work will be let in three separate and distinct contracts, not necessarily to the same individual.

Tenderers are required to examine the localities of the work and are requested to be present at the opening of the tenders at 2 p.m., on Wednesday, the 17th day of September, 1913.

Plans and specifications may be seen at the office of the County Engineers, Messrs. Jackson and Kyd, Dunnville, or may be had from them on the payment of $10, which sum will be refunded on return of the documents.

Lowest or any tender not necessarily accepted.

T. A. SNIDER, K.C.,
County Clerk,
County of Haldimand,
Cayuga, Ont.

TENDERS FOR MACHINERY.

TOWN OF NEEPAWA, MAN.

Specification Section No. 1— 2 72 ft. by 18 ft. boilers.

Specification Section No. 2—1 187½ h.p. engine.

Specification Section No. 3—1 150 K. V. A. generator exciter and switchboard.

Specification may be obtained by applying to W. E. Skinner, Limited, Consulting Engineers, 204 Sterling Bank Building, Winnipeg, or to the undersigned, or may be seen at the offices of *The Canadian Engineer*, 820 Union Bank Building, Winnipeg; 62 Church Street, Toronto, or 628 Transportation Building, Montreal.

J. W. BRADLEY,
Secretary-Treasurer, Neepawa, Man.

CITY OF REGINA, SASK.

Sealed tenders, registered and clearly marked on the outside of the envelope "Tender for Power-House Equipment," and addressed to the City Commissioners at Regina, Sask., will be received up till noon of October 1st, 1913, for the supply of:—

Coal bunkers, ash hoppers, coal and ash conveyers and crushers.

Price to be on equipment erected on foundation built by the City of Regina according to contractor's requirements.

A marked cheque for 5 per cent. of the amount of the bid, and made payable to the City Treasurer, City of Regina, must accompany each tender.

Specifications may be obtained from E. W. Bull, Superintendent of Light and Power, Regina, Sask.

The City Commissioners reserve the right to reject any or all tenders.

(For Further Tenders see page 84.)

MUNICIPAL OFFICIALS ARE INVITED TO FILE PLANS AND SPECIFICATIONS OF PROJECTED WORK AT ANY OF THE **CANADIAN ENGINEER** OFFICES—IT WILL BE FOUND A CONVENIENCE TO CONTRACTORS AND WILL RESULT IN MORE AND BETTER BIDS BEING SUBMITTED

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

(Continued from Page 75.)

20022—August 14—Approving proposed alteration in C. L. O. and W. Ry. Co.'s railway so as to include the extra lands required for station grounds in Lots 9 and 10, Con. Broken Front, Tp. Clarke, Co. Durham, Ont., at mileage 137.2 from Glen Tay; and approving location of C. L. O. and W. Ry. station building in Lot 9, Con. B. F.

20023—August 14—Authorizing the C.P.R. to construct its tracks across the roadway in Lot 1088, Kootenay District, B.C., at mileage 48.69, from Golden, by means of a grade crossing.

20024—August 13—Authorizing C.P.R. to construct bridge No. 92.7 on the Toronto Subdivision, Ontario Division, Don Viaduct, near Donlands, Co. York, and Province of Ontario.

20025—August 11—Recommending to the Governor-in Council for approval, By-law No. 40, and the Rules and Regulations for the Government of Employees of the Hull Electric Co.; and rescinding Order No. 19938.

20026—August 13—Granting leave to R. H. Edgar, Bowling Green, Ont., to erect, place and maintain telephone line across the tracks of the C.P.R. at Lot 3, Con. 4, Twp. Amaranth, Co. Dufferin, Ont.

20027—August 14—Authorizing the Dom. Atlantic R. to construct bridge No. 125.9 at the Jordantown Road crossing, N.S.

20028—August 13—Further extending for a period of six months from date of this Order, the time within which the Esquimalt and Nanaimo Ry. Co. was required to file Standard Tariff of maximum freight tolls for the approval of the Board.

20029—August 13—Authorizing the C.P.R. to construct bridge No. 39.4, Toronto Subdivision, Ontario Division of its railway.

20030—August 14—Authorizing the C.P.R. to construct for and on behalf of the municipality, subways at Scotia, Parkside, and Main (Kildonan Road) Streets, and East Kildonan Road, Man.

20031—August 14—Authorizing the C.P.R. to make alterations in the foot bridge at Wallace Avenue to carry it over the third track which the C.P.R. is now constructing from Parkdale to West Toronto.

20032—August 14—Authorizing the C.N.O.R. to construct a subway over the public road on Lots 81 and 82, Parish of Ste. Dorothee, Co. Laval.

20033—August 13—Approving location of the C.N.R. station grounds at Amable, Twp. Pentland, District of Nipissing, Ont., at mileage 188.5 from Ottawa.

20034—Authorizing the Canadian Northern Railway to open for the carriage of traffic portion of its diverted line, Oak Point Branch, from a point in Sec. 21, Tp. 11, Rge. 2, E. P. M., a distance of 3.27 miles.

20035—August 14—Authorizing G.T.P. to cross highway at mileage 210.4, Rural Municipality of Ellice, Dist. of Shoal Lake.

20036—August 15—Approving location G.T.P. Prince Rupert westerly line, from mileage 2.25 (Seal Cove), to mileage 3.23, in the Province of British Columbia.

20037—August 14—Authorizing G.T.P. to construct spur for C. S. Hyman and Company, Calgary, Alta.

20038—August 14—Authorizing G.T.P. B.L. Co. to construct Third Street under this railway at mileage 46.8, in the town of Battleford, Sask.

20039—August 13—Relieving G.T.R. from providing further protection at Brant House Crossing, east of Burlington Station.

20040—August 8—Authorizing certain changes or alterations in C.L.O. & W.'s line so as to provide station grounds in the town of Bowmanville.

20041—August 13—Extending until Nov. 1st, 1913, time for completion of spur for Coquitlam Terminal Company, Limited, Vancouver, across Dominion, 5th, 6th, and 7th Avenues, by C.P.R.

20042—August 9th.—Authorizing C.P.R. to construct branch line to premises of General Fire Extinguisher Company, Montreal.

MEXICAN EAGLE ASPHALT

TRADE MARK

When big paving companies

like the Warner-Quinlan Company use MEXICAN EAGLE ASPHALT *exclusively for all their work in Canada, there must be high merit in that asphalt. If their pavements don't "stand up," the Warner-Quinlan Co. are the ones who lose. The guarantees required are long; repair work is expensive. The best of asphalt must be used. For six years Mexican Eagle Asphalt has "won the pennant" for quality.*

INTERIOR VIEW OF ONE OF THE BUILDINGS OF OUR TEHUANTEPEC PLANT, MEXICO

Our principals, The Mexican Eagle Oil Co., Ltd. (Lord Cowdray, Chairman), have $25,000,000 working capital. They guarantee EVERY BARREL to be uniform and according to analysis. This plant has sufficient capacity to supply Canada with 75,000 tons a year of the world's finest asphalt if that much is required.

DOW & SMITH say that we have a very high quality of refined asphalt; that it is excellent in every respect for pavements. Their reports show that Mexican Eagle Asphalt is especially adapted to our Canadian climate as it will not "mark up" in the warmest weather, nor has extreme cold any bad effect on it. It is the ideal asphalt for paving purposes. Analyses show 99% pure bitumen. Lays between 85 and 90 square yards to the ton.

Refined to definite standards

For prices, samples and full particulars, please address

TRANSPORTATION BUILDING — MONTREAL

SECOND-HAND MACHINERY

FOR SALE

Plant of the Alberta Engineering Company, Limited, in Manchester Sub-division, Calgary, Alberta; building 96 x 34, equipped with electric power, complete machinery with individual motors for structural steel plant, made up as follows:—

High-speed Friction Saw, 40 inch blade, electric drive.
Rock River Power Shear, belt driven, 32 inch gap.
Rock River Punching Machine, belt driven 30 inch gap.
Stewart Drill Press, belt driven, up to 1⅛ inch dia. drill.
Landis Bolt Cutter, belt driven, up to 1½ inch bolt.
Power Hack Saw.
Jib-boom Derrick, 40 foot boom.
Allan Squeeze Rivetter, 18 inch gap, compressed air.
Blaisdell Air Compressor, belt driven, 8 x 8, with receiver and cooling tank.
Gardner Air Compressor, 6 x 6, mounted on truck, with motor drive.
Grinder, 24 inch mandrill, double head, belt drive.
Two 10 H.P., 3 phase, 60 cycle, 220 volt motors.
One 15 H.P., 3 phase, 60 cycle, 220 volt motor.
Two 5 H.P., 3 phase, 60 cycle, 220 volt motors.
One 2 H P., 3 phase, 60 cycle, 220 volt motor.
All with starting boxes.
Two 3 ton "Cyclone" Chain Blocks.
One 2 ton Chain Block.
Boyer Air Hammer, 8 inch stroke.
Cleveland Pneumatic Hammer, size 9.
Cleveland Pneumatic Hammer, size 6, with snaps and hose complete.

The foregoing may be inspected at the plant of the Alberta Engineering Company, located as above, at any time, any working day, and will be offered for sale as a going concern or in individual units.

E. A. CUNNINGHAM,
Liquidator,
Alberta Engineering Company, Ltd.

Contractors' Machinery For Sale

We have in stock for immediate delivery:—

6½"x8", 6"x12", 7"x12", 8"x12", Beatty hoists
5"x6", builders' reversible hoist
1 yd. "Faivrette" clam bucket
No. 2, boom swinger
No. 2, Ransome concrete mixer
No. 3, Ransome concrete mixer
No. 2 Austin portable stone crusher
10" x 10" x 10", steam driven air compressor
4", 5" and 6", centrifugal pumps direct connected to vertical engines
5, 8 and 12 ton, stiff-leg derrick irons

SELLING AGENTS FOR M. Beatty & Sons

H. W. PETRIE, Limited
TORONTO, ONT.

20 H.P. CASOLINE or KEROSENE I.H.C. Tractor; nearly new; perfect condition; $1,450. Arnold Forster, Newcastle, Ont.

FOR SALE at a snap: 60-H.P. Cowan and Co. engine and 80-H.P. Cowan and Co. boiler. Write for particulars, J. F. Barnard and Son, Spencerville, Ont.

FOR SALE.—One second-hand Marion steam shovel; model 20; has seen very little service and is in fine repair. Also one second-hand Marion shovel; model 30; revolving; in good repair. Low price for immediate sale. Address, R. B. Stewart, Whitby, Ont.

FOR SALE.—Complete Sewer and Water Contractor's outfit, including one Parsons' Trench Excavator, Trench Braces, Fire Pots, Pumps, etc. For price and terms apply to Navin Bros., Contractors, Moose Jaw, Sask.

GAS ENGINE, 8 h.p., for sale cheap; in first-class condition. M. Pullan and Sons, Bay and Wellington Streets, Toronto.

PATENTS.

August 18th, 1913.

The following is a list of patents recently issued through the agency of Messrs. Ridout and Maybee, 59 Yonge Street, Toronto, from whom further particulars may be obtained:—

Canada.—Jas. R. Hoyle and A. W. Brearley, casting ingots; Thomas Newton, stair tread coverings; George Evans, detachable heals; Thomas Gill, turbines, turbine pumps and turbine compressors; Ernest Buchholtz, liquid fuel burners and furnaces; George Norman, bolt action rifles; John G. Robinson, pressure release valves.

United States.—Richard C. Quin, feeding systems for oil burners; William Park, tellurians.

Russia.—Frederick L. H. Sims, key bolts.

Australia.—H. E. T. Haultain, weighing apparatus.

France.—Louis Huffman, variable speed mechanism.

CURRENT NEWS.

Calgary, Alta.—The question as to whether all the 18 money by-laws now ready to go before the ratepayers be submitted on one day, or divided up and submitted on different days, was decided by the City Council recently. Assistant City Clerk James Barnes asked for a decision, and, after some consultation, a motion was adopted directing that they be submitted on separate days, and that the matter as to the dates and what by-laws should be submitted together, be left to the city commissioners, with power to act.

MONTREAL MARKET LETTER.

Montreal, August 25th.

Considerable interest has been displayed in the announcement that the Canada Iron Corporation had gone into the hands of a receiver. From all that can be learned, this will not mean that the plants of the company will have to be closed down and the statement has been made that operations will be continued, though not on the authority of those at the head of the company.

It will be recalled that the company some time since, closed down its big Midland furnace. The statement is made that the company was unable to compete with the offerings from the United States.

With the exception of the above, no change of consequence has taken place in the iron and steel markets. Prices are generally steady and trade is undoubtedly lighter than it has been at this time of year during the past few years. The reports of employees being laid off on the railways and in other industries, is naturally not very encouraging, but the general view is that as soon as the money market gets into shape again, building and construction will once more go ahead, inasmuch as so much of it is needed to keep up with the requirements of the country.

CANADA Portland CEMENT

SOME men ask for so many bags of "cement"—

Others, more careful, say they want "Portland Cement"—

But the man who does the best work insists upon getting "Canada" Portland Cement—

And he looks to see that every bag bears this label

To specify Canada Portland Cement, is to introduce an additional safety factor into your calculations. Architects, contractors and engineers know the value of "making assurance doubly sure."

Positions Wanted

Advertisements under this heading one cent per word per insertion. Minimum charge fifty cents per insertion.

DO YOU NEED MALE HELP.—Canadian or foreign labor furnished for all classes of work, skilled or unskilled, for office, construction work, waterworks, paving, dams, and wharves. We can put men on the job for you cheaper than you can get them any other way, write or phone for particulars to O'Donnell's Employment Bureau, 116 Wellington Street West, Toronto. Phone Adelaide 3919.

ELECTRICAL AND MECHANICAL ENGINEER,—25 years' experience, desires superintending position. First-class references. Electric lighting, power, mining, or similar line of work preferred. Please address Box 62, *The Canadian Engineer*, Toronto.

EXPERIENCED ENGINEER desires appointment, preferably as municipal or sanitary engineer. Technical education; twenty years' experience in the design and construction of drainage, sewerage and sewage disposal systems; street and road construction. Also limited experience in topographical surveys, water supply, town planning and plumbing design. Member of the American Society of Civil Engineers, and of the Royal Sanitary Institute. Please address replies in first instance to Box 66,, *The Canadian Engineer*, Toronto.

ENGINEERING SALESMAN open for engagement. Excellent experience in selling mill power and mining machinery. Good references. Will be pleased to keep any appointment made through Box 70, *The Canadian Engineer*, Toronto.

MECHANICAL ENGINEER—Experienced Designer, Cost Estimator and Salesman, Works Supervision, all kinds of steam engines, boilers, hydraulic pumps, air machinery and mining plants, seeks position with Consulting Engineer, Contractor, Manufacturers or agency business. Highest references, some capital. Box 102, *The Canadian Engineer*, Toronto.

SUPERINTENDENT SEEKS re-appointment on heavy work, experienced in big plant, steam shovel work, rock, hardpan, concrete, etc. Highest references. Box 110, *The Canadian Engineer*, Toronto.

YOUNG CANADIAN ENGINEER.—Experience, paper mill, electric substation, hydraulic power plant, field and office, wishes to get in touch with a manufacturing concern requiring the services of a permanent resident engineer or plant chief; superior references. Address Box 112, *The Canadian Engineer*, Toronto.

YOUNG ELECTRICAL ENGINEER desires position either as consulting or plant engineer; first-class character and education; one who will take an interest and make good. Box 114, *The Canadian Engineer*, Toronto.

MECHANICAL ENGINEER resident in Toronto desires position; wide experience in manufacture and installation; would accept temporary post; references. Box 116, *The Canadian Engineer*, Toronto.

SUPERINTENDING ENGINEER of construction now free to accept appointment. Large experience on public works, with specialty in tunnelling. Unexceptional references. Nine years' U.S.A. experience. Address T. H. D., Bartram & Wadsworth, Bank of Toronto Building, Toronto.

EXPERIENCED MUNICIPAL ENGINEER and Land Surveyor desires position. Ten years' experience in municipal engineering, two years as superintendent of construction; also experience in construction of concrete bridges and buildings, railway and land surveys and drainage works. Toronto graduate; O.L.S. seven years, A.M. Can. Soc. C.E. five years. Engagement of three to six months' duration acceptable; at present in the West. Address Box 122, *The Canadian Engineer*, Toronto.

Condensed Advts.

Advertisements under this heading three cents per word per insertion. Minimum charge fifty cents per insertion.

MANUFACTURER of well-known waterproofing is open to receive applications from responsible agents for the sale of his product in Montreal and vicinity. Address Box 118, *The Canadian Engineer*, 617 Transportation Buildings, Montreal.

UNITED STATES MANUFACTURERS of concrete mixers is anxious to make agency arrangement with energetic salesman for the territory in and around Toronto. Address Box 120, *The Canadian Engineer*, Toronto.

PATENT NOTICES.—Any one desiring to obtain the invention covered by Canadian Patent No. 135303 granted on August 29th, 1911, to George O. Squier, of Washington, D.C., for telephony and telegraphy, may do so upon application to the undersigned, who are prepared to supply all reasonable demands on the part of the public for the invention and from whom full information may be obtained. Fetherstonhaugh and Company, 53 Queen Street, Ottawa, Canada, Russel S. Smart, manager.

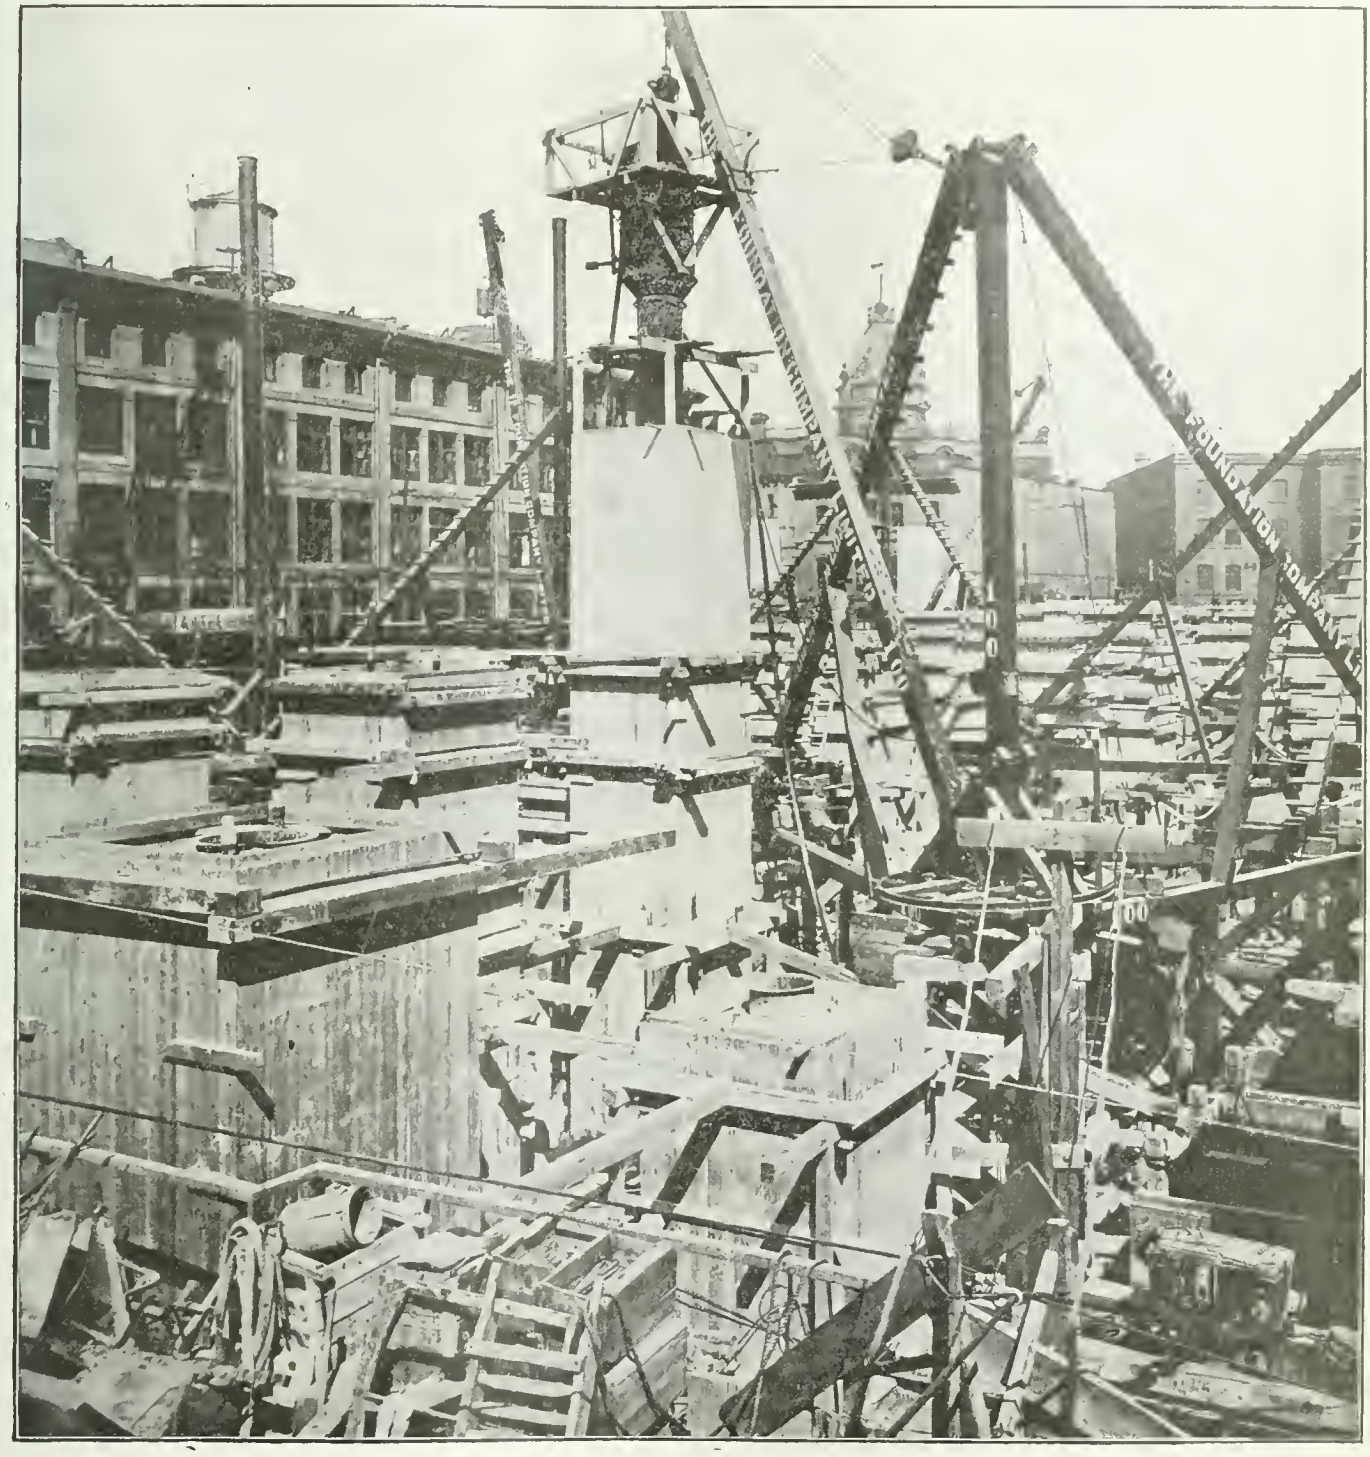
THE FOUNDATION COMPANY

MONTREAL LIMITED VANCOUVER



COMPRESSED AIR

Has helped to engineer some of the world's most famous Tunnels, Bridges and Skyscrapers. Under modern methods and organization it has become a speciality. The above shows the foundations for a new building in Montreal with caissons in various stages.

MARKET CONDITIONS

Montreal, August 23rd, 1913

Bar Iron and Steel.—Trade is reported active. Bar iron, $2.10 per 100 pounds; best refined horsesboe, $2.35; forged iron, $2 25; mild steel, $2.20; sleigh shoe steel, $2.20 for 1 x ⅜ base; tire steel, $2.30 for 1 x ¾ base; toe caulk steel, $3; machine steel, iron finish, $2.25.

Cement.—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1.40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re-purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain.—The market is quoted per 100 lbs. as follows:—¼-in., $5.65; 5/16-in., $4.70; ⅜-in., $4.00; 7/16-in., $3.65; ½-in., $3.45; 9/16-in., $3.45; ⅝-in., $3.35; ¾-in., $3.25; ⅞-in., $3.15; 1 in., $3.05.

Explosives and Accessories.—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus.—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron.—The market is steady. Prices, basis, 28-gauge, are:—Queen's Head, $4.40; Colborne Crown, $4.20; Apollo, 10¾ oz., $4 30. Add 25c. per 100 lbs. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge. American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe.—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No 1 Summerlee, $22.50 per ton; selected Summerlee, $22; soft Summerlee, $21.50 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron, number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19.25 to $19.50 per ton, on track.

Laths.—See Lumber, etc

Lumber, Etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph Poles: seven-loch top, cedar poles, 25-ft. poles, $2 each; 30-ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 10c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce, 4-ft x 1½-in., mill run, $3 to $3.25; pine, 4-ft. x 1½-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2.10; XX, $2.40; XXX, $2.80.

Pipe.—Cast Iron.—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe.—Wrought and Galvanized.—Demand is fair and the market steady: —¼-inch $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ⅜-inch, $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent off for black and 59 per cent. off for galvanized. The discount on the following is 72½ per cent. off for black and 62½ per cent. off for galvanized: ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22 50; 1½-inch, $27. On the following the discount is 72½ per cent for black and 62½ per cent. for galvanized:—2-inch, $36; 2½-inch, $57 50, and 3-inch $75.50; 72½ per cent. off for black, and 62½ per cent. of for galvanized; 3½-inch, $95; 4-inch, $1.08.

Toronto, August 27th 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron.—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel.—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates.—½-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes.—Orders continue active. Lap-welded, steel, 1¼-inch, 10c.; 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3¼-inch, $15; 4-inch, $19.

Bricks.—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $13 to $15 per M., three grades.

Broken Stone.—Lime stone, good hard, for roadways or concrete, f.o.h., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto, 60 cents.

Cement.—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot.—The market is lower at 15⅝ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps.—75c. and $1 per 100; case lots, 5,0000, 20 per cent. off.

Dynamite.—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¾ cents pound, 1 to 0-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1½c. per hundred. For 10-case lots and over deduct ¼ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1⅝ cent.

Fuses.—Electric Blasting. Double strength, $1.50 per hundred, advance 54c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 54c. per hundred for each 2-in. wire additional.

Iron Chain.—¼-inch, $5.75; 5-16-in, $5.15; ⅜-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8 inch, $3.55; ¾ inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe.—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.10; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40.60; 6-inch, $52.64. Galvanied Pipe, ¼-inch, $2.86; ⅜-inch, $2.86 ½-inch, $5.57; ¾-inch, $4.31; 1-inch, $6.10; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead.—Firmer, $5.25 to $5.50.

Pig Iron.—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar.—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate.—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being sleader and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green, $8, with a prospect of advance. Dealers are fairly busy.

Sand.—Sharp, for cement or brick work, $1.25 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe.—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0.25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00
Double junctions	1.25	2.00	3.25	5.00	16.25
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. H. traps	2.00	3.20	6.50	15.00	.....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes, 9 inches and under or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels.—Active.—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2.75 to $3 per 100 pounds. Extra for smaller sizes of angles and tees.

Sheet Copper.—22c. per lb.

Sheet Steel.—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized.—Apollo Brand.—Sheets, 6 or 8 feet long, 30 or 36 inches wide; 10-gauge, $3.00; 12-14-gauge, $3.00; 16, 18, 20, $3.30; 22-24, $3.40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 pounds. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin.—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel.—Jowett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates.—3-16-inch, $2.40 per 100 lbs.

Zinc.—Spelter.—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, August 26th, 1913.

Anvils.—Per pound, 11½ to 13½c.; Buckworth anvils, 80 lbs. and up, 10½ to 10½c.; anvil and vise combined, each $5.50.

Bar Iron.—$2.50 base.

Bars.—Crow, $4.50 per 100 pounds.

Beams and Channels.—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick.—Kiln run per M, $13; sewer per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland.—$2.40 to $2.50 per barrel.

Chain.—Cail, 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7-16, $4.75; ½, $4.50; 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5½c. Tie out, 70 and 10 per cent.

Copper.—Tinned, boiler, 26½c., planished 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent discount.

Dynamite.—$11 to $13 per case.

Galvanized Iron.—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20, $4; 18, $3.95; 16, $3.90; Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30; 22, $4.30; 20, $4.10 per cwt.

Iron.—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4, 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26-gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American, $5.15; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe.—Iron, black, per 100 feet, ⅜-inch, $2.40; ½-inch, $2.55; ¾-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7.80; 1½-inch, $9.35; 2-inch, $12.50; galvanized—⅜-inch, $4.35; ½-inch, $5.20; 1-inch, $7.35; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch.—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled.—3-16-in., $3.35 base; machinery, $3 base; share, $4.50 base; share crucible, $5.50, cast share steel, $7.50; toe calk, $4.50 base; tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel.—8½ to 15c. per pound

SPIRAL OR SCREW CONVEYERS

SPECIALLY REQUIRED FOR CONVEYANCE OF CERTAIN MATERIALS —GENERAL DESCRIPTION—CAPACITY UNDER VARIED LOADING HORSE-POWER REQUIRED — NET OPERATING COST.

By REGINALD TRAUTSCHOLD, M.E.,
Consulting Engineer, New York City.

IN many industrial plants, whether power houses, cement mills, or of other types, certain operations frequently require the more or less continuous handling of materials that are often of such nature as not to permit efficient use of carriers of the flight conveyer type or of any type in which the load carried is exposed to possible disarrangement by air currents, etc. Then, too, the required capacity is frequently relatively small, making the installation of a system of large capacity of questionable economy, owing to the intermittent service that would be required from such apparatus. In such cases, a popular and sometimes very desirable equipment is the screw or spiral conveyer, a conveyer that possesses the advantages of relatively low first cost and of extreme compactness. This type of carrier consists of a suitable metal ribbon wound spirally about a shaft to form a screw which, enclosed in a box or trough, pushes the material handled forward as the screw is revolved. At intervals, gates or openings may be made in the bottom of the trough through which the material conveyed is discharged or else the material may be carried to the end of the trough, which is invariably left open, and there dumped out. The diameter of the trough may be only slightly larger than that of the screw, in which case practically all material fed to the conveyer is propelled forward as the screw revolves, or the trough may consist of a relatively large box surrounding the screw, which gradually fills with material until the screw forms its own trough and pushes forward the additional material fed to the conveyer. The first type of trough is usually found in installations for carrying fine coal, grain, small cement clinkers and other "fines," while the latter is almost always limited to installations for handling ashes, etc., which may be temporarily stored in the conveyer trough or box and subsequently removed through gates in the bottom of the storage box. Naturally only fine materials can be efficiently handled by such a conveyer, and while these materials need not be necessarily homogeneous in character they should contain no lumps more than a few inches in size, the maximum allowable size of lump depending somewhat upon the diameter of screw, i.e., size of conveyer. The screw conveyer is at its best when handling fine and light substances, materials that could not be carried by any other type of conveyer without a great deal of spill. This is particularly noticeable in cement mills where screw conveyers are often employed to handle fine cement clinker containing a great deal of air. In such installations the squeezing action of the helical ribbon of the conveyer also tends to compress the clinker and displace much of the air contained on its receipt from the kilns. The efficient length of screw conveyers is also limited for, though the flight is interrupted every few feet to accommodate supporting bearings for the screw shaft, the torsional strain on the screw shaft becomes unduly severe if the conveyer is more than about 100 feet in length, unless the material handled is very light and has a small angle of repose—such as grain.

The size of screw conveyers (diameter of screw) is usually limited to about 24 inches, though conveyers have been built and successfully operated that were upward of 3 feet in diameter, and, as the speed at which they can be efficiently operated is also limited to about 250 revolutions per minute, their carrying capacity must therefore be relatively small. Actually three conditions govern the capacity of screw conveyers; 1st, the diameter of the screw; 2nd, the pitch of the screw; and 3rd, the speed at which it is run, i.e., revolutions of the screw; but the question of mechanical efficiency of the apparatus—the mechanical efficiency being at a maximum with a screw pitch of 45 degrees—has led to the universal practice of making the pitch of the screw about the same as its diameter, so that only speed and size of conveyer need be considered for a standard equipment. The speeds usually employed are from 100 to 250 revolutions per minute, the higher speeds for conveyers of small size, irrespective of either character or weight of material conveyed. Table III. gives the average capacity of various standard sizes of screw conveyers when operated at their respectively most economic speeds, expressed in terms of bushels handled per hour. Table IV. gives similar data expressed in terms of tons of material weighing 100 pounds per cubic foot handled per hour. Material of other weight or carried at different conveyer speeds vary directly proportionally as the weight and speed. The carrying capacity of screw conveyers is further dependent upon the depth of material in the trough, or rather the proportion of the screw that would be submerged in the material should it be possible to push the material forward with no agitation, and this is limited to a depth equivalent to about one-third the diameter of the screw, so it is possible

to evolve a formula for the derivation of carrying capacity of any size of screw conveyer at any speed, expressed in terms of the square of the diameter of the screw, the pitch of the screw and the revolutions made by the screw in a given time. As the pitch and diameter of the screw are usually equal, the variable quantities are simply those of size of conveyer (diameter of screw) and speed of conveyer (revolutions of screw). Such relationship is expressed in Formulæ VI. and VII., the former giving the capacity in terms of bushels per hour and the latter in terms of tons per hour.

Table III.

Capacity of Screw Conveyers, Continuously and Uniformly Loaded.

Diameter of Screw	Speed R.P.M.	Bushels per hour	Diameter of Screw	Speed R.P.M.	Bushels per hour

$B = 0.0088022\ d^3R$ Formula VI.

$W = 0.000003213\ d^3w'R$ Formula VII.

Where :—

B = Capacity in bushels per hour.
W = Capacity in tons per hour.
d = Diameter of screw in inches—size of Conveyer.
w′ = Weight of material conveyed in pounds per cubic foot.
R = Revolutions of screw per minute.

The consumption of power by screw conveyers is naturally relatively high on account of the low mechanical efficiency of the screw; that is, the power requirements are similar to those of an ordinary flight or scraper conveyer corrected for the inclined plane action of the screw construction to which must be added the loss of power or thrust due to the mechanical inefficiency of the screw. The power consumed in running the empty conveyer is not affected by the pitch of the screw, of course, being virtually that required to revolve the screw at the required speed, but the greater power requirements for propelling the load depend directly upon the pitch of the screw and must be corrected accordingly. Theoretically there is also a difference in power consumption by screw conveyers depending upon the nature of the material handled, its weight, angle of repose, etc. Practically, however, no great variations are found in power requirements of screw conveyers handling different materials as ordinarily installed and subjected to the abuse to which such apparatus is invariably submitted. Though formulæ have been derived which provide for varying power requirements by the substitution of various constants for conveyers destined to carry specific materials, the following formula (Formula VIII.) gives approximately accurate results for ascertaining the power requirements of practically any screw conveyer handling suitable material at advisable speeds. This formula allows for an inclination to the conveyer (elevating the material) which allowance is about equal to the amount that would be required to simply raise the specified weight through a vertical distance equal to the difference in elevation between the two ends of the conveyer. Actually, some additional power might be required, owing to appreciable increase in thrust on conveyer bearings, but the capacity of the conveyer is also somewhat reduced by any inclination so that the derived horse-power is practically accurate for the load actually conveyed. As much of the material that is frequently handled by screw conveyers is customarily measured in bushels rather than in tons, Formula IX. will be found to be of convenience when such unit is the base of measure. Chart II., giving the power requirements for screw conveyers in both terms of tonnage capacity and of capacity in bushels, will also be found to be of decided assistance. The accuracy of chart reading is not as great, of course, as is attainable when relying upon formulæ, but, for all practical purposes, such readings are sufficiently accurate.

Horse-power :

W = Weight of load conveyed in tons per hour = $0.00015065\ d^3R$ (aver.)
V = Velocity (speed) of Conveyer in feet per minute = $0.2618\ dR$
d = Diameter of Conveyer (screw) in inches.
L = Length of Conveyer in feet.
H = Height to which load is elevated in feet.
R = Revolutions of screw per minute.
W_s = Weight of moving parts per foot of Conveyer in pounds.
= $0.1\ d^2$—average value.
W′ = Weight of load conveyed per foot of Conveyer in pounds per minute.

$$= \frac{33\ W}{V}$$

f_s = speed factor = 0.09—from experiment.
f_l = load factor = 0.70—from experiment.
d′ = diameter of screw shaft in inches = 0.15d—average value.
V′ = Velocity of screw shaft in feet per minute = $0.03927\ dR$.

Work in foot pounds per minute required to run Conveyer empty.
= $W_s \times f_s \times V \times L = 0.00035303\ d^3RL = 2.343\ WL$—av. value.

Work in foot pounds per minute required to convey load.
= $W' \times f_l \times V \times L \times 0.3183 = 7.35\ WL$ (neglecting inefficiency).
= 20.1 WL (correcting for inefficiency of screw).

Horsepower required to elevate load (inclined conveyer).

$$= \frac{WH}{1000}$$

Then :—
Total horsepower required.

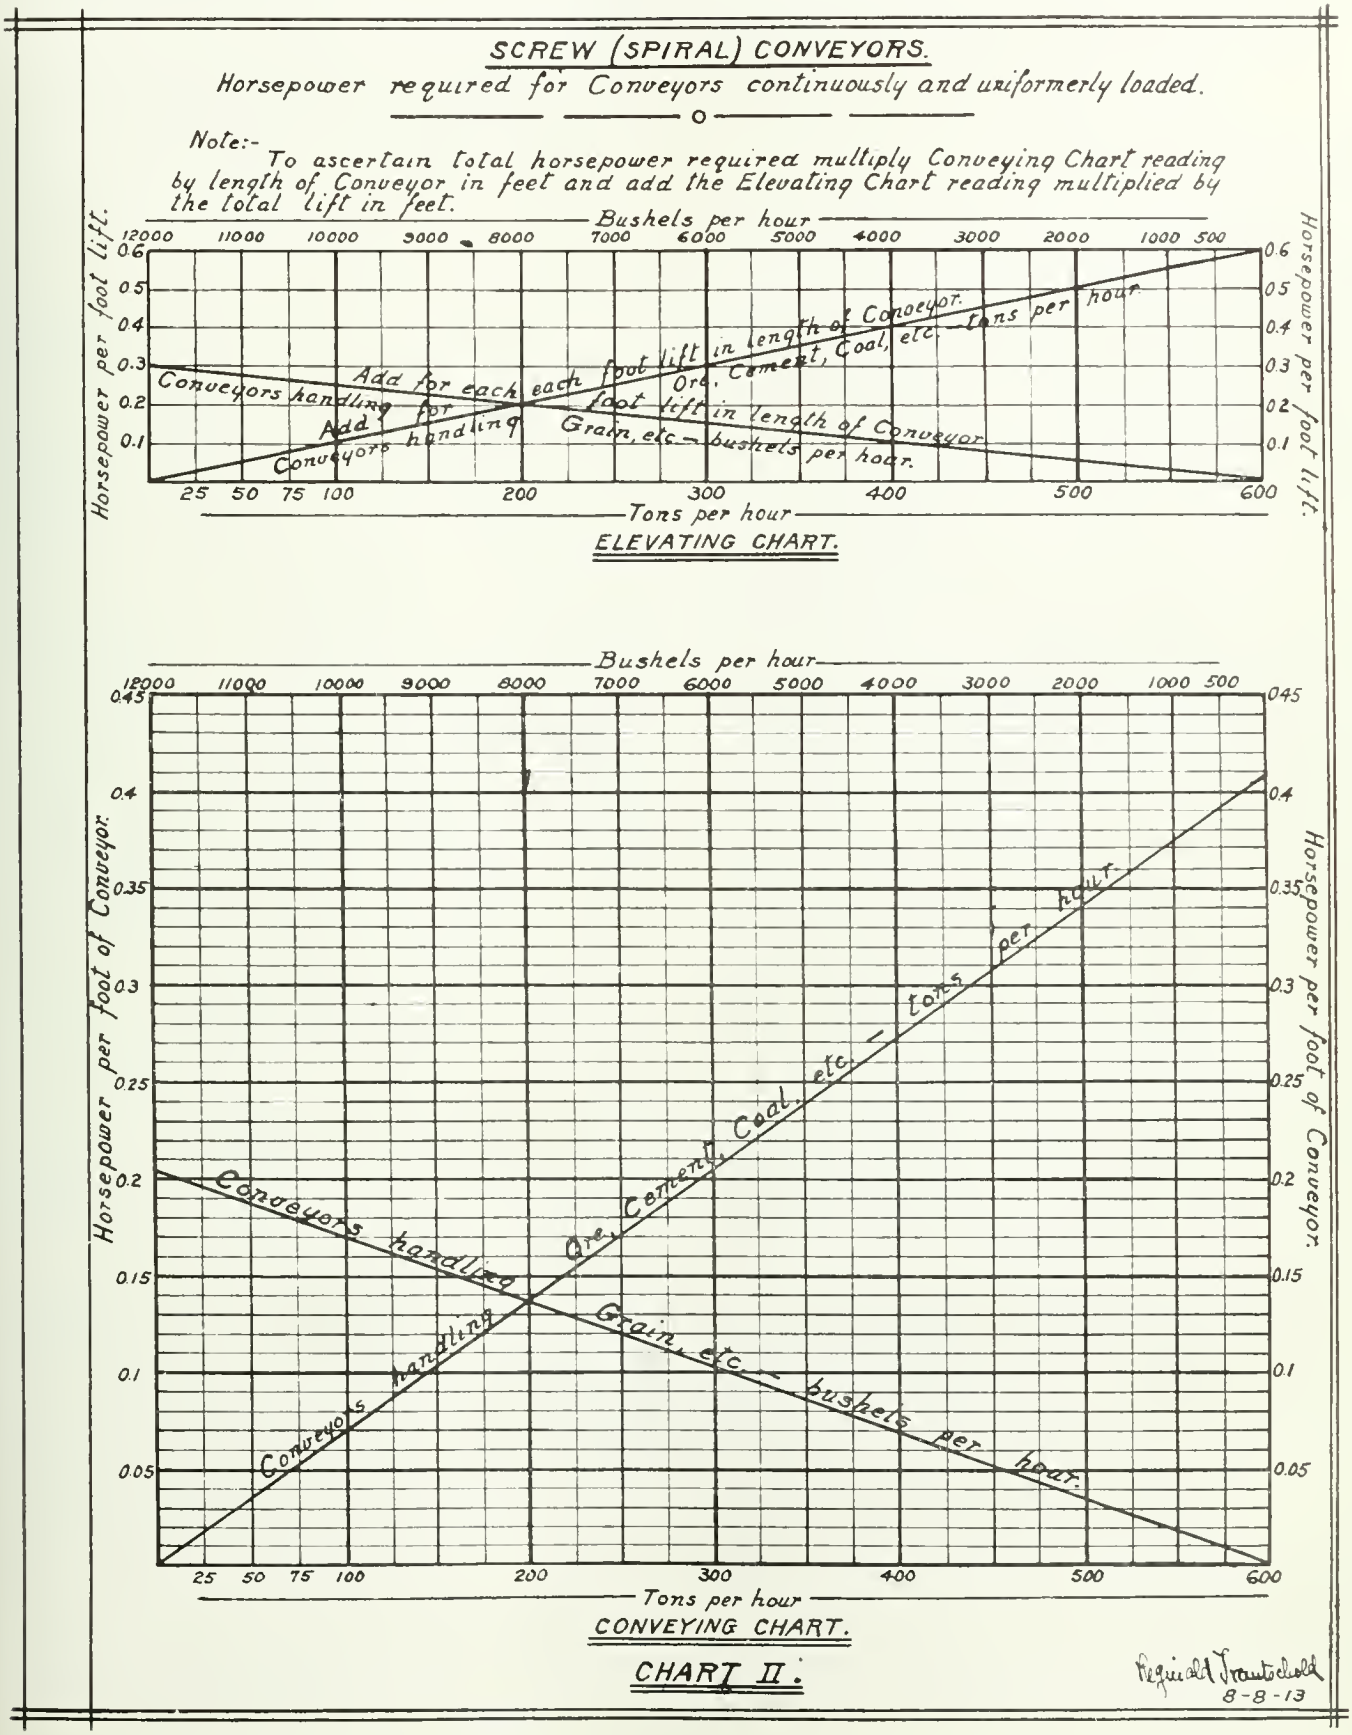
$$HP = \frac{0.68\ WL + WH}{1000}$$ Formula VIII.

$$HP = \frac{0.017\ BL + 0.025\ BH}{1000}$$ Formula IX.

B = Load conveyed in bushels per hour.

The standardization of screw conveyers in the matter of pitch and the large factor of safety that must be used in proportioning the various parts of the screw, etc., in order to permit economical manufacture, has created a close relationship between the weight of the screw, hangers, bearings, driving mechanism, etc., and the size of the conveyer and correspondingly a close relationship between the average cost of such parts and the diameter of the screw, size of conveyer. Likewise, the trough is usually a comparatively heavy casing slightly larger than the screw or a relatively large box with a correspondingly light lining, so that the cost of the stationary parts of a screw conveyer also vary closely with the size of the conveyer. For rough approximations, sufficiently accurate

for conservative estimates of the average burden of interest on investment, depreciation, renewals, insurance, taxes, etc., an equation can be derived for ascertaining the average cost of equipment in which the only variable quantities are those of length of conveyer and diameter of screw, the various items constituting a complete equipment varying directly with the diameter of the screw, except for the ends of the conveyer which vary closely with the square of the diameter of the screw. Such an equation is given as Formula X., and its use gives a fairly accurate estimate of the initial cost of any screw conveyer, including an average allowance for covering cost of erec-



SCREW (SPIRAL) CONVEYORS.
Horsepower required for Conveyors continuously and uniformerly loaded.
Note:- To ascertain total horsepower required multiply Conveying Chart reading by length of Conveyor in feet and add the Elevating Chart reading multiplied by the total lift in feet.

tion and of the ordinary supporting structures required—items which should be rightfully charged against initial cost of equipment.

Cost of Equipment:

C = Cost of Screw Conveyer equipment in dollars.
d = diameter of Conveyer (screw) in inches.
L = Length of Conveyer in feet.

Average cost of screw per foot of Conveyer	0.1653 d
hangers, etc., per foot of Conveyer...	0.0107 d
trough and gates per foot of Conveyer	0.0200 d
driving machinery per Conveyer.....	2.3233 d
ends, etc., per Conveyer	0.0700 d^2

Then:—

$C = 0.196\ dL + 2.3233\ d + 0.07\ d^2$ Formula X.

This low cost of machinery is naturally a decided advantage and though the power requirements of screw conveyers are heavy as compared with some other types of conveyers, their compactness and general efficiency in handling comparatively small quantities of material, at a decided saving over the expense that would be entailed if manual labor had to be resorted to, make them very desirable in many installations, besides which their peculiar construction possesses certain advantages that are very desirable for special uses. To form a really reliable opinion as to their true economic value, however, the overhead charges must be taken into consideration. The burden of interest on investment, insurance, taxes, etc., is about constant for any specific size of conveyer, irrespective of the nature or character of the load handled, and, knowing the average cost of equipment, can be proportioned to the carrying capacity of the conveyer—whether the carrying capacity be expressed in bushels or in tons. Depreciation is dependent upon the severity of the service to which the conveyer is subjected, however, being greater in conveyers that handle cement, ore, coals and gritty materials than in the case of grain conveyers. Even in the case of the more trying conditions, depreciation would not be constant if exactly similar conveyers were used for handling the various materials, but this variation is controlled in great measure by the choice of the correct conveyer, i.e., material and strength of component parts. For instance, the screws of conveyers for handling cement, coal, small stone of ordinary hardness, many kinds of ore, etc., are usually of heavy steel construction while the screws of conveyers for handling ashes, more gritty ores, etc., are frequently of cast iron. The difference in material does not have much effect upon the initial cost of equipment—hence, practically none on the percentage or proportional part that represents depreciation—but does equalize the depreciation from abrasive wear. Grain conveyers are usually of lighter steel construction, but this does not materially reduce their cost, though their life is usually considerably in excess of that of conveyers subjected to the more severe conditions of wear. It is advisable, therefore, to differentiate between grain conveyers and those used in the more difficult operations of handling ores, cement, ashes, etc., in considering the net cost of operation. Attendance is about constant for any specific size of conveyer of given length, irrespective of the material handled, while renewals and repairs, like depreciation, are somewhat variable, depending upon the character of the load handled. Power consumption depends nearly entirely, in a well-designed and proportioned conveyer that is properly operated and cared for, upon the quantity of material handled. The expense for lubricants, waste and other incidental supplies also varies approximately with the consumption of power or quantity of material handled. The foregoing relationships being pretty accurately known, it is possible to derive equations for ascertaining the average net cost of operation of screw conveyers upon which a reliable opinion of their economic value can be based. Such equations are given as Formulæ XI. and XII., the former applying to grain conveyers and giving the net operating cost per bushel handled and the latter applicable to screw conveyers handling ores, coal, ashes, cement, etc., etc., giving the average net operating cost per ton of material conveyed.

Net Operating Cost (N.O.C.) of Screw Conveyers:

L = Length of Conveyer in feet, max. distance load is carried.
H = Height (distance) through which load can be elevated in feet.
N = Number of hours (total) Conveyer is in use per year.
P_c = Price (cost) of a horsepower per hour in dollars.

GRAIN CONVEYERS.

B = Bushels conveyed per hour (capacity of Conveyer).

Average cost of equipment:—
$= 0.01703\ BL + 0.02458\ B.$

Fixed Charges:—

Then:—NET OPERATING COST (N.O.C.) PER TON.

$$N.O.C. = \frac{21.367\ L + 12.017 + (68\ LP_c + 101\ HP_c + 50\ L)N}{100{,}000\ N}$$ Formula XII.

Examples.

1. Conditions:—

Length of Conveyer..	30′ 0″	= L
Material elevated	8′ 0″	= H
Service.....	2400 hours per year	= N
Cost of power... .	$0.02 per horsepower per hour	= P_c

Material handled—Grain

$$\text{N.O.C.} = \frac{11430 + 299 + 89808}{240000000} = \$0.000423 \text{ per bushel.}$$
$$= 42.3 \text{ cents per thousand bushels.}$$
Equivalent to about $0.01692 per ton.

II. Conditions:—
The same as Example I, except that service is 12000 hours per year.

$$\text{N.O.C.} = \frac{11430 + 299 + 44904}{120000000} = \$0.000472 \text{ per bushel.}$$
$$= 47.2 \text{ cents per thousand bushels.}$$
Equivalent to about $0.01888 per ton.

III. Conditions:—
The same as Example I, except that the material handled is fine (small size) coal.

$$\text{N.O.C.} = \frac{641 + 12.017 + 3736704}{240000000} = \$0.01557 + \text{per ton}$$

IV. Conditions:—
The same as Example III, except that service is 1200 hours per year.

$$\text{N.O.C.} = \frac{641 + 12.017 + 1868352}{120000000} = 0.01558\text{—per ton}$$

Assuming conditions that are commonly encountered in practice, the accompanying examples well illustrate the real economic value of the screw conveyer and they also bring out apparently surprising facts. Under the conditions considered, it will be noted that the screw conveyer is not relatively as economical a method of handling grain as it is for handling heavier materials such as coal, ore or cement—that is, when measured by weight of material conveyed. This is true even though the depreciation, renewals, repairs and similar expenses are only about one-third as great in a grain conveyer as in a conveyer subjected to the more severe operations of handling the heavier materials. The reason for this is that proportionally to the weights of the materials the capacity of a screw conveyer is very much less when handling the relative light grain and, as less power is also required for the operation of any given size of conveyer of specified length carrying grain, the burden represented by interest on investment, insurance and taxes, which amounts to a more or less constant sum per year, irrespective of the nature of the material handled or the number of hours the equipment is in operation, is, in the case of the relatively light grain, considerably greater per weight of material handled. The average weight of grain, etc., is from 25 to 50 per cent. lighter than the weight of a similar quantity of ore, cement, etc., and though the economic value of a screw conveyer as a carrier for the two classes of materials does not vary to quite such an extent, still, an appreciable difference does exist. Another interesting point brought out by the examples is that the economic value of the equipment is not affected as much by the hours of operation when handling the heavier materials as when carrying the lighter grains. This is also due to the fact that for the more severe work the item of power is very much greater proportionally than when the working conditions of the conveyer present less difficulty. Nevertheless, screw conveyers are frequently employed in the handling of grain and of materials of similar nature and are decidedly economical at such service; particularly when they are long, as then the overhead burden is somewhat lessened.

A modification of the standard type of screw conveyer that has been considered is extensively used in the mixing of several materials while they are, at the same time, being conveyed from one location to another. For instance, in the mixing and delivery of concrete. Such conveyers usually have the spiral flight in the form of succeeding paddles in place of a continuous ribbon, or else have double flights, one a ribbon flight for conveying and the other a system of paddles for agitating and mixing the ingredients. These adaptations, however, although they are examples of apparatus for mechanically handling materials, should not be classed with standard types of conveying machinery, the principal subject of the present discussion.

[Note.—This is the second of a series of articles bearing upon the Mechanical Handling of Materials written for *The Canadian Engineer*. A third article will follow in an early issue.—Ed.]

WATERPROOFING OF CONCRETE.

Although it did not arrive at sufficiently definite conclusions to enable it to formulate specifications for the making of concrete structures waterproof, or for materials to be used in such work, the Committee on Waterproofing Materials, of the American Society of Testing Materials, reached certain conclusions which will be of assistance in securing impermeable concrete. These formed the basis of the committee's report at the convention in Atlantic City in June.

The work was found to subdivide naturally into three branches:

1. The determination of causes of the permeability of concrete, and the best methods of avoiding these causes.

2. The rendering of concrete more waterproof by adding other substances.

3. The treatment of exposed surfaces after the concrete or mortar has been put in place, either by penetrative, void-filling or repellent liquids, making the concrete itself less permeable; or by extraneous protective coatings, preventing water having access to the concrete.

These several subdivisions were considered separately:

Causes of Permeability of Concrete.—In the laboratory and under test conditions using properly graded and sized coarse and fine aggregates, in mixtures ranging from 1 cement, 2 sand and 4 stone to 1 cement, 3 sand and 6 stone, impermeable concrete can invariably be produced. Even with sand of poor granulometric composition, with mixtures as rich as 1 cement, 2 sand and 4 stone, permeable concrete is seldom, if ever, found and is a rare occurrence with mixtures of 1 cement, 3 sand and 6 stone. But the fact remains, nevertheless, that the reverse often obtains in actual construction, permeable concretes being encountered even with 1 cement, 2 sand and 4 stone mixtures, and are of frequent occurrence where the quantity of the aggregate is increased. This the committee attributed to:

(a) Defective workmanship, resulting from improper proportioning, lack of thorough mixing, separation of the coarse aggregate from the fine aggregate and cement in transporting and placing the mixed concrete, lack of density through insufficient tamping or spading, and improper bonding of the work joints, etc.

(b) The use of imperfectly sized and graded aggregates.

(c) The use of excessive water, causing shrinkage cracks and formation of laitance seams.

(d) The lack of proper provision to take care of expansion and contraction, causing subsequent cracking.

Properly graded sands and coarse aggregates are rarely, if ever, found in nature in sufficient quantities to be available for large construction, and the effect of poorly graded aggregates in producing permeable con-

crete is aggravated by poor and inefficient field work. Even if the added expense could be afforded of screening and remixing the aggregates so as to secure proper granulometric composition to give the density required to make untreated concretes impermeable, it is seemingly often a commercial impossibility on large construction to obtain workmanship even approximating that found in laboratory work.

Addition of Foreign Substances.—The committee found that, in consequence of the conditions outlined above, substances calculated to make the concrete more impermeable, either incorporated in the cement or added to the concrete during mixing, are often used.

The committee had investigated a sufficient number of the special waterproofing compounds on the market, as well as the use of certain very finely divided mineral products, such as finely ground sand, colloidal clays, hydrated lime, etc., to form a general idea of the value of the different types. It reported that:

(a) The majority of patented and proprietory integral compounds tested have little or no immediate or permanent effect on the permeability of concrete and that some of these even have an injurious effect on the strength of mortar and concrete in which they are incorporated.

(b) The permanent effect of such integral waterproofing additions, if dependent on the action of organic compounds, is very doubtful.

(c) In view of their possible effect, not only upon the early strength, but also upon the durability of concrete after considerable periods, no integral waterproofing material should be used unless it has been subjected to long-time practical tests under proper observation to demonstrate its value, and unless its ingredients and the proportion in which they are present are known.

(d) In general more desirable results are obtainable from inert compounds acting mechanically than from active chemical compounds whose efficiency depends on change of form through chemical action after addition to the concrete.

(e) Void-filling substances are more to be relied upon than those whose value depends on repellent action.

(f) Assuming average quality as to size of aggregates and reasonably good workmanship in the mixing and placing of the concretes, the addition of from 10 to 20 per cent. of very finely divided void-filling mineral substances may be expected to result in the production of concrete which under ordinary conditions of exposure will be found impermeable, provided the work joints are properly bonded, and cracks do not develop on drying, or through change in volume due to atmospheric changes, or by settlement.

External Treatment.—While external treatment of concrete would be necessary if the concrete itself, either naturally or by the addition of waterproofing material, was impermeable, it was found in practice that in large construction, no matter how carefully the concrete itself has been made, cracks are apt to develop, due to shrinking in drying out, expansion and contraction under change of temperature and moisture content, and through settlement.

It is, therefore, often advisable on important construction to anticipate and provide for the possible occurrence of such cracks by external treatment with protective coatings. Such coating must be sufficiently elastic and cohesive to prevent the cracks extending through the coating itself. The application of merely penetrative void-filling liquid washes will not prevent the passage of water due to cracking of the concrete. The committee therefore, divided surface treatment into two heads:

(a) Penetrative void-filling liquid washes.

(b) Protective coatings, including all surface applications intended to prevent water from coming in contact with the concrete.

While some penetrative washes may be efficient in rendering concrete waterproof for limited periods, their efficiency may decrease with time, and it may be necessary to repeat such treatment. The committee, expressed its belief that the first effort should be made to secure a concrete that is impermeable in itself and that penetrative, void-filling washes should only be resorted to as a corrective measure.

While protective extraneous bituminous or asphaltic coatings are unnecessary, so far as the major portion of the concrete surface is concerned, provided the concrete is impermeable, they are valuable as a protection where cracks develop in a structure. It therefore recommended that combination of inert void-filling substances and extraneous waterproofing be adopted in especially difficult or important work.

Bituminous or Asphaltic Coatings.—Considering the use of bituminous or asphaltic coatings, the committee found that:

(a) Such protective coatings are often subject to more or less deterioration with time, and may be attacked by injurious vapors, or deleterious substances in solution in the water, coming in contact with them.

(b) The most effective method for applying such protection is either the setting of a course of impervious brick dipped in bituminous material into a solid bed of bituminous material or the application of a sufficient number of layers of satisfactory membranous material cemented together with hot bitumen.

(c) Their durability and efficiency are very largely dependent on the care with which they are applied.

Such care refers particularly to proper cleaning and preparation of the concrete to insure as dry a surface as possible before application of the protective covering, the lapping of all joints of the membranous layers, and their thorough coating with the protective material. The use of this method of protection is further desirable because proper bituminous coverings offer resistance to stray electrical currents.

Richer Mixtures.—So far the committee had considered only concretes of the usual proportions, namely, those ranging from 1 cement, 2 sand and 4 stone, to 1 cement, 3 sand and 6 stone. It was suggested that impermeable concretes could be assured by using mixtures considerably richer in cement. While such practice would probably result in an immediate impermeable concrete, the advantage is believed to be only temporary, as richer concretes are more subject to check cracking and are less constant in volume under changes of conditions of temperature, moisture, etc. Therefore, the use of more cement in mass concrete would cause increased cracking, unless some means of controlling the expansion and contraction be discovered. With reinforced concretes the objection is not so great, as the tendency to cracking is more or less counteracted by the reinforcement.

It was also suggested that the presence in the cement of a larger percentage of very fine flour might result in the production of a denser and more impermeable con-

crete, through the formation of a larger amount of colloidal cells.

Neither of these suggestion was especially investigated by the committee. Both appealed, however, for the reason that they substitute active cementitious substances for the largely inactive void-filling materials previously recommended, thus increasing the strength of the concrete.

In conclusion, the committee pointed out that no addition of waterproofing compounds or substances could be relied upon to counteract completely the effect of bad workmanship, and that the production of impermeable concrete could only be hoped for where there is determined insistence at all times on good workmanship.

The production of impermeable concrete has assumed greater importance since the appointment of the committee, owing to the well-known injurious action of saline or alkaline waters, and to the suggested possible effect of the moisture in concrete occasioning or aggravating electrical action from stray currents.

Originally the question of waterproofing involved mainly the physical troubles resulting from water passing through the concrete, without any special consideration of its effect on its durability, other than a gradual leaching out of the cement. Recent developments suggest the possibility that owing to the increased conductivity of damp concrete to electrical currents, such currents, if present, may so effect damp concrete as to lessen its integrity seriously, and this possibility further emphasizes the importance of the recommendation that no waterproofing compound of unknown chemical composition be added to concrete, as recent tests seem to show that the action of electrical currents is aggravated by the presence of certain solutions.

THE CANADIAN PUBLIC HEALTH CONGRESS.

The third annual Congress of the Canadian Public Health Association will be held in Regina, September 18th, 19th and 20th. The city hall has been placed at the disposal of the members for the general sessions, while sectional meetings will be held in Regina College, the Board of Governors having granted the use of its buildings for this purpose.

The social functions of the Congress will include a luncheon at the Parliament Buildings on September 18th, tendered by the Government of Saskatchewan, the annual dinner of the Association to take place that evening, when the members will be the guests of the city of Regina; a visit to the city sewage disposal works on the following day, and on the last day of the Convention a trip to Fort Qu'Appelle, one of Saskatchewan's summer resorts, where the new sanitorium buildings are under construction.

The programme for the general session includes seventeen papers. Section I., for Medical Officers of Health; Section II., Medical Inspection of Schools; Section III., Military Hygiene; Section IV., Veterinary Hygiene and Food Inspection; Section V., Sanitary Inspectors; Section VI., Engineers and Architects; Section VII., Laboratory Workers; Section VIII., Social Workers. All have individual lists of papers bearing directly upon the science of public health.

Arrangements have been made with the Eastern and Western Passengers' Association whereby a standard certificate can be obtained at any railway station entitling the holder to reduced return fair, the advice of the committee being to purchase a one-way ticket to Regina, securing at the same time the standard certificate.

THE DETERMINATION OF THE MAGNETIC MERIDIAN.

By J. A. MacDonald.

THERE had not been much done in the way of determination of the magnetic meridian at various points throughout Canada until a short time ago, when the Topographical Surveys Department of which Dr. Deville is at the head, took up this work in connection with Dominion land surveys in the Western provinces. Nothing of much account has yet been done in the older provinces by the Canadian Government, although the United States geogetic surveys branch has done considerable work in various parts of the Dominion in the way of determining magnetic declinations. The writer, a few years ago, determined the magnetic declination, at a point in one of the Maritime Provinces where no observation for magnetic declination had ever been made for the United States Geogetic Surveys. Data has, of course, been furnished by the Marine Department at the various harbors in Canada, for the information of navigators, but this data is of no value to those using compasses on land.

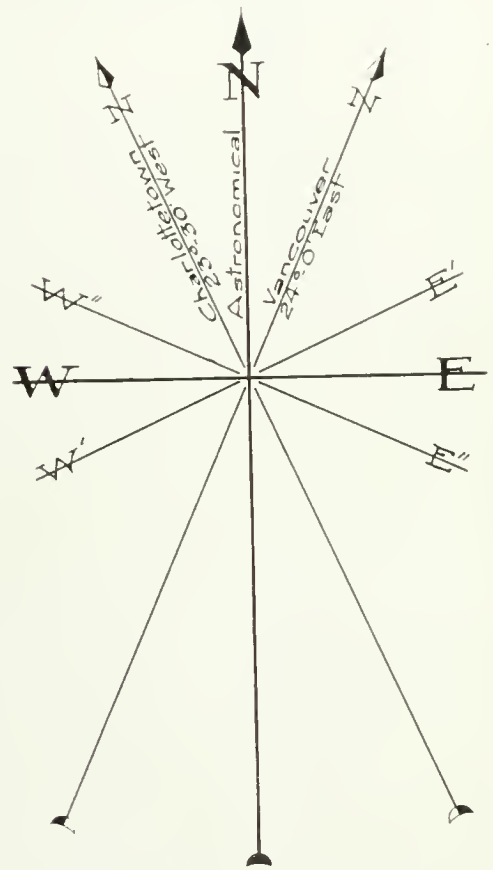

Fig. 1.—Magnetic Declinations.

The Magnetic Needle Still Used for Establishing Lines.—Although the compass is not allowed for establishing lines of Dominion land surveys, it is employed by most of the older provinces, and a knowledge of the direction of the magnetic meridian or of the magnetic declination is of absolute importance. The directions given for obtaining magnetic declinations in the Manual for Dominion Land Surveyors is very explicit.

For the determination of this direction, transit theodolites of the D.L.S. pattern are fitted with especially

sensitive needles. As the observation can be made in a few minutes and with very little trouble, it is desirable that all surveyors should observe when they can do so without inconvenience.

The observation and recording forms are arranged for the determination of the bearing of the magnetic needle instead of the magnetic declination. The arrangement is made for the sake of simplicity in observing and recording, the bearing in question being, subject to instrumental corrections, the angle read on the horizontal circle of the transit. Moreover, it is not liable to errors of sign, as in adding or subtracting the declination.

Directions for Observing.—Place the instrument on a section or other line, defined astronomically, and after adjustment, set the vernier to read the astronomical bearing of the line.

Release the lower clamp, direct the telescope on the line, and fasten the lower clamp.

Release the vernier clamp, and turn the vernier plate until the north end of the magnetic needle observed with a magnifying glass, is seen exactly opposite the zero mark. Tap the trough lightly with the pencil to be sure that the needle has taken the position of rest. Note the reading of the horizontal circle. Take several readings by repeating the operation.

Repeat the third operation for the south end of the needle.

Enter in the notes the place of observation, date, hour of the day, weather and other remarks, if any. It is important to record auroras occurring within 24 hours of the time of observation.

Remarks on Observations.—For saving trouble and calculations, it is suggested that observations be made on any lines of which the bearing is known.

The direction of the magnetic needle is subject to a daily fluctuation called the diurnal variation. During the greater part of the night the direction is not far from normal. In the early morning, the north end of the needle in Canada moves towards the east, reaching its maximum deflection about 7 or 8 a.m. The motion is now reversed, the north end travelling westwards, and crossing the normal direction about 10 or 11 a.m. The extreme western position is reached in the afternoon and then the needle comes back to its normal position at some time after 5 or 6 p.m. This march is subject to wide variations during magnetic storms. The magnitude of the diurnal variation is not constant. In the inhabited parts of Canada, it may exceed 20 minutes. Observations at both eastern and western elongations of the needle on the same day, that is, between 7 and 8 a.m. and between 1 and 2 p.m., give the best results, and it is desirable that when convenient they may be taken then. This gives not only the best value for the declination, but also the diurnal variation which it is most useful to know. Failing this, however, the best time to observe is after 5 p.m., when the needle is about in its normal position. It is true that the normal position is crossed generally between 10 and 11 a.m., but the motion being very rapid and the time of crossing uncertain, the afternoon observation is preferable.

When an instrument is brought from England, where many of the transits and compasses are made, it is usually found that the north end of the needle is dropping. To balance it without injuring the pivot point or cap, proceed as follows:—

Raise the needle with the lifter, unscrew the end of the trough, withdraw the cover glass, take out the needle and shift the small brass counterweight. Then the lifter being still raised, place the needle upon it and lower the lifter gently. If the needle is not yet balanced, raise the lifter again and repeat the operation. The greatest care must be taken not to bend the needle in the slightest degree while shifting the counterweight, because the bending would change the direction of the magnetic axis.

If the needle is sluggish, the observation cannot be accurate. The sluggishness is generally due to a dull pivot or a scratched cap. To keep both in proper condition, the needle must always be lowered gently on its pivot and never be allowed to play, except when actually in use.

OBSERVATION FOR MAGNETIC DECLINATION

Date 19th July 1908 Observer G.J. Lonergan D.L.S.

Place 40 Chs. E of the S.E. Cor. of Sec. 5

Tp. 50 Rge. 20 W. of 4th Mer.

Time 7.15 P.M. Instrument Watts #2216 (Give No.)

Bearing of reference line 89° - 59'

H. C. R. FOR DIRECTION OF MAGNETIC NEEDLE.

	NORTH END.	SOUTH END.
(1)	27 - 15'	27 - 17
(2)	11	16
(3)	12	10
(4)	11	10
(5)	10	12
Mean of North End.	27 - 11.8	Mean of South End. 27° - 13.0'

(a) H. C. R. of compass north	27 - 12.4'
(b) Corr. for convergence	- 1.2

(d) Index error	5.8
(e) Bearing of magnetic north	27 - 05.4

REMARKS.

A few clouds Windy

No aurora.

Fig. 2.

Explanation of Specimen Observation.

1. The H.C.R. of compass north is the average of the mean north and south end readings. The transit was adjusted to read correctly the bearing of the section line, so that the horizontal circle reading of compass north is the bearing of compass north referred to the astronomical meridian through the centre of the township. If the transit had not been so adjusted a correction to this reading would have been required.

2. The correction for convergence has for object to refer the bearing read on the horizontal circle to the astronomical meridian of the point of observation. The value of the correction is taken from the diagram in the

Astronomical Field Tables. It is added when the point of observation is in the east half of the township, and subtracted in the other half. The rule of clause 69 of the Manual is inverted, the object in this case being to refer the bearing to the meridian of the point of observation.

3. The bearing of compass north has now been referred to the meridian of the point of observation.

4. The index error is furnished with each instrument after comparison with the unifilar magnetometer.

5. The bearing of magnetic north is the angle formed by the astronomical and magnetic meridians.

There are instances of the polarity of the needle being reversed by transporting an instrument on an electric car. It is difficult to conceive that a needle may be brought into such an intense magnetic field as that of an electric car without its magnetism being effected in some way, therefore, it is preferable to avoid this mode of transportation.

The place of observation must be at least three or four hundred yards away from electric wires carrying direct current. The observer must scrutinize his clothing and make sure that he has no iron or nickel on his person, as there must be no iron near the instrument. Iron is found in buttons, as wire in hat brims, in some forms of neckties, in watches, chains and other articles of jewelry. The pivot in folding reading glasses is frequently made of iron. In case of doubt, the object may be tried close to the compass, measuring the distance at which an appreciable deflection is first produced. If the object during the observation for declination is not brought closer than 15 or twenty times the above distance, the effect on the needle is negligible in observations of this kind.

The needle may be deflected by static electricity developed in cleaning the glass cover of the compass trough or the rubber frame of the reading glass; this electricity is dissipated by breathing on the glass or rubber frame.

There is an index correction for each instrument. This is ascertained by comparison with a standard unafilar magnetometer at the Magnetic Observatory. When possible, it is well to determine the index error both at the beginning and at the end of a survey.

Setting a Transit by Means of the Compass.—In connection with surveys of Dominion lands, the most frequent use of the compass is for checking the courses of a traverse or for setting up the transit to read astronomical bearings.

In the first case, it is sufficient to make sure that there is no abnormal change in the reading of compass north: any sudden change indicates a probable mistake in some of the last courses.

The second case arises when it is desired to observe the pole star in day time at a place where there is no line of known bearing. The problem consists in setting up the transit so that it shall read astronomical bearings. If the surveyor has already ascertained the bearing of compass north with his instrument, he merely sets his vernier to read this bearing, releases the lower clamp, turns the whole instrument till the needle is exactly opposite the zero mark, fastens the lower clamp and releases the vernier clamp. With the instrument used for the specimen observation and anywhere near the place where the observation was taken, the vernier would be set to read 25°, or rather 25° 07′.

It may be, however, that the surveyor has not ascertained the bearing of the compass north with his own instrument and has to resort to the bearing of magnetic north taken from a map or determined by another surveyor. Then the surveyor must, from the bearing of magnetic north, deduce the bearing of compass north by applying the index error of his own instrument after changing the sign. Starting with 25° 01′.1, for bearing of magnetic north in the case already cited, and the index error being—51′.8, the surveyor would add 5′.8 to 25° 01′.1, which would give him 25° 06′.9 for the bearing of the compass north. He would then proceed as already explained.

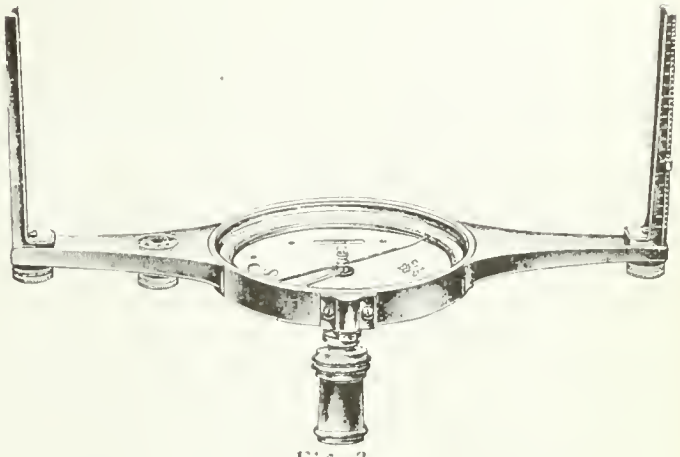

Fig. 3.

All these corrections, it may be observed, are generally small and in practice are frequently disregarded.

Line of no Declination.—The line of no declination, or the line which a needle will indicate a true north and south direction is situated in any imaginary line drawn from Sault Ste. Marie to Charleston, South Carolina. A magnetic needle placed east of this line has a declination to the west, and when placed west of the line a declination to the east; and in both cases it increases as the needle is carried farther from the line of no declination.

Thus, in Vancouver, the declination is twenty-four degrees to the east, at Winnipeg eleven to twelve, to nothing at the Soo; while east of the Soo the declination is west, increasing from nothing, to 23½ degrees, at Charlottetown, Prince Edward Island. The declination is now said to be decreasing.

It is to be noted in determining lines of declination that the needle does not remain constant through an entire day, but reaches its farthest point east about 8 o'clock a.m., and its farthest point west about 2 o'clock p.m. The cause of this daily variation of the needle is not understood, as observations show that it is greater in summer than in winter.

Conditions of temperature, magnetic storms and other causes at times affect the needle and different needles observed at the same time and under the same conditions differ in their directions, but show nearly the same daily change.

Gaspe Bay district has high hopes of oil-producing possibilities. In view of the increasing attention being given to the adoption of oil in the Royal Navy and the decision of the Imperial Government to secure supplies so far as possible within the Empire, there opens up the prospect of another large Canadian industry. The admirable shipping facilities which the district possesses are receiving attention.

ROAD MAINTENANCE AND COST.

By Hector F. Gullan, M. Inst. C.E.,
Superintendent to the Works Department of the City and County Borough of Belfast.

SCIENTIFIC road maintenance is not only the mere continuance of an existing form of road surface by the most approved methods, but should mean the providing of a road surface which is best suited for the traffic it is called upon to bear having regard to (*a*) cost of maintenance and cleansing, (*b*) economy in regard to wear and tear on the traffic using same, (*c*) noiselessness, and (*d*) hygienic qualities.

At the present time the road surfaces most generally in use may be classified as follows: (1) Macadam water consolidated; (2) macadam tar-bound or pitch-grouted; (3) sett paving on existing foundations; (4) sett paving on concrete foundations; (5) natural asphalts on concrete foundations; (6) wood blocks (hard) on concrete foundations; (7) wood blocks (soft) on concrete foundations.

To secure efficient road maintenance the quality of the various materials used and workmanship employed must be carefully determined, and, along with a systematic inspection, records should be kept of the intensity of the traffic, wear and tear and costs, in order to ensure good work and ascertain the relative merits of various methods adopted.

In dealing with the maintenance of a road the first essential is that the road, including the foundation, shall be sufficiently substantial to support the traffic passing over it, and where such is not the case, either in patches or over considerable lengths, it will be found to tend to ultimate economy to go to considerable expense, either in strengthening the roadway generally or renewing the foundations.

Water-consolidated macadam roads, which, at the present time, form by far the greater percentage of the road surfaces of the country, have, on account of the growth of motor traffic of all kinds, proved themselves to be, in spite of the greatest care being exercised in the selection of the material and skilful workmanship, in many cases altogether unsuitable. In several cases the cost of maintenance has increased during the last eight years as much as 100 per cent., and along with this increase the nuisance arising from dust has become almost intolerable.

In selecting the stone for repair work the greatest care must be taken to obtain a thoroughly hard and tough material, and it has been the practice of the author for some years to test mechanically the stone from various quarries in a form of "rattles" machine. The stone submitted for testing, after being broken to a standard size, is carefully weighed and placed inside the machine. The number of revolutions per minute is uniformly regulated, and an automatic recorder indicates the number of revolutions during the period of the test. The stone is afterwards removed from the cylinder and again weighed, and the percentage of loss due to wear and tear ascertained. This machine has been found to be of the greatest value in determining the wearing qualities of various stones.

After every care has been taken to determine the wearing quality of the stone to be used in the maintenance of roads, there is yet one condition which must be carefully observed, especially in the case of road surfacing, in order to obtain entirely satisfactory results—it is, ensuring that the material used over a given surface is of a uniform quality. The indiscriminate use of two or more stones of different qualities, even when relatively good, both in paved streets and macadam roads, will be found to produce very disastrous results. On macadam roads in particular the traffic will very soon find out the spots where the softer material is situated. Where the surface begins to wear down below the harder material surface water will gather, slightly at first and gradually increasing, with the result that the crust of the road is softened, and the less hard material is subjected to the disintegrating effects of the weather to a far greater degree than the other parts of the road, thereby causing further damage, and, in combination with the traffic, the wear goes on daily in an increasing ratio, and the general surface of the road rapidly becomes a series of hills and hollows.

Before recoating a macadam road the custom is to scarify the surface of the old road crust. After gathering all loose material to the side, a coat of about 3 in. of new metal is carefully spread, and before being rolled the old material from the side of the road is uniformly scattered over the new stone. This coat is rolled dry until all the stones are firmly bedded in position, and is then lightly sprinkled with water. A coating of ½-in. screenings or chippings is then spread, the screenings having been first damped. This coat is then watered sufficiently to allow the roller to work over the same without picking up the material, and from time to time additional water is sprinkled until the binding material has gradually worked its way into the interstices. Two men are employed in front of each roller lightly brushing the ½-in. chippings so that the surface is uniformly fed with the fine stone. It is found that the screenings being damped before use find their way more uniformly between the stones, and that the fine material is not washed through the new stone, but helps to close the road crust along with the coarser chippings.

The author is of opinion that in many cases the quantity of water used in consolidating a macadam road is considerably overdone. In wet weather on flat roads little or no water is necessary. In Ireland in the dryest of summer weather not more than 3½ gallons of water per square yard of road surface is required. The average quantity of water used last year on upwards of 220,000 sq. yds. was somewhat over 400,000 gallons, and works out at 1.84 gallons per square yard. A final coat of gravel, about ⅛ in. in depth, greatly assists in finishing the road surface, and protects a new road from the effects of traffic.

In the North of Ireland, on account of the variable climate, tar-spraying has not met with any considerable success. The greatest difficulty has been found in carrying out the work during suitable weather, and in many cases the mud arising in the winter from roads which have been thus tarred has given a great amount of trouble.

Except where very heavy traffic exists, on a properly maintained ordinary macadam road a general patching of the surface should never be necessary, and where, owing to exceptional circumstances, such repairs have to be undertaken, the work should only be done during wet weather. The method found most satisfactory has been to slightly rough the surface of the road requiring such repair, and to make use of stone of 1½-in. gauge, blinding the new surface with a sufficient coating of ½-in. chippings from which the stone dust has not been extracted. These are carefully packed by the surfaceman, and

*Extracted from a paper presented to the "Surveyor," of London.

all such patches are tightened up twice or three times daily with a brush. In ordinary wet weather, with proper attention, such patches will consolidate under the traffic and become an integral part of the road surface in about three days.

Tar-Macadam Roads, Etc.—A very large number of methods are in operation in the preparation of a tar-macadam or pitch-grouted surface, and the author, in submitting his remarks under this heading, wishes it to be understood that he in no way dogmatizes as to the best form of construction, but rather desires to convey the principles which have guided him in arriving at his present method.

In the manufacture of tar-macadam it is essential that all moisture should be expelled from the stone, and that after it has become absolutely dry the heated stone should be thoroughly mixed with the boiling tar preparation. The heat used for the drying of the stone should be duly regulated, and the proper proportion of boiling tar applied to thoroughly coat all the particles of stone.

In Belfast an entirely novel tar-macadam plant has been devised by the author by which the resources of a refuse destructor have been availed of for drying and heating the stone and boiling the tar mixture, which, if required, can deal with an output of 10,000 tons per annum, and has been working with entire satisfaction from June, 1910.

The general features are as follows: The stone supplied from the quarries is delivered at a high level to the drying towers. In its passage, by gravity, through the towers the stone is thoroughly dried and heated, and passes out at the lower end into a revolving mixer. Boiling tar, of sufficient quantity to thoroughly coat the stone, is also fed into the mixer, and the whole discharged at the outlet, thoroughly mixed, in the form of tar-macadam.

To obtain the heat from the furnace gases before passing up the destructor chimney a by-pass or loop has been built alongside the main flue, and two dampers or doors (one on the main flue and the other on the by-pass) have been built in at either end to regulate the passage of these gases. Into the by-pass a tubular air heater has been built through which, by means of a fan, fresh air is drawn and driven forward at a high temperature into the drying towers, where, after passing through the stone, it finds its way out at the top of the towers. The temperature of the hot air delivered to the drying towers is recorded by a pyrometer, and the heat required is regulated by the opening and closing of the dampers in the flues, and a cold-air inlet valve situated between the heater and the fan.

A cylindrical revolving mixer receives the stone from the outlets of the drying towers, and as the stone passes into the mixer it is treated with boiling tar delivered from one of a pair of tar-boilers on either side.

The power to drive the shafting and belting is derived from the destructor engine.

Twin towers are provided to secure a continuous supply of stone, the stone from one tower being drawn while the other is drying and heating. This arrangement also applies in the case of tar-boiling, and should it be required, there would be no difficulty in working continuously night and day.

Tar-macadam may be laid upon an existing roadway provided the levels of footpaths or abutting buildings will allow. If this is not the case, the surface of the existing roadway must be cut away to provide a sufficient depth for the new coating of tar-macadam, the formation being left to correspond with the finished camber of the tar-macadam. The camber generally adopted on a level tar-macadam road is 1 in 30, while on an incline this may be reduced to 1 in 40, or even 1 in 45. In the case of a tar-macadam road the foundation must be sufficient to support the road traffic independent of the road crust for at least twelve months after the tar-macadam has been laid; there is, in warm weather, a certain amount of "give" in the crust, which, if the road is not to disintegrate as a consequence of the traffic, must be entirely supported by the foundation.

Difficulty has been found in securing uniformity in the distribution of the various sizes of stone in the mass where the aggregate is prepared with mixed sizes, with the result that the road surface wears unequally. It has therefore been found desirable to lay the material in three separate layers, the utmost care being taken that all material shall be uniformly spread and rolled. The bottom layer, being of 1½-in. material, is first spread to a depth of 4 in. and compacted by light rolling, the intermediate coat of 1-in. material being then laid 2 in. in depth, and the two coats thoroughly combined by careful rolling. A top coat of ½-in. material is finally added and the surface rolled until the whole crust is thoroughly compacted. No advantage is obtained by an excessive amount of rolling. Only sufficient material is used in the top coat to thoroughly key the surface, and when finally consolidated the whole forms a tar-macadam crust 4 in. in thickness. After the road has been laid from six to nine months the surface is thoroughly cleansed, dressed with boiling tar, the surplus tar being absorbed and retained by covering off with a coating of fine stone dust. This tar painting may be repeated every two years, and greatly adds to the life of the surface crust.

In regard to repairs, it is of the utmost importance that any patching should be carried out as soon as the surface shows undue indications of wear, always providing that the work is done in dry weather. In executing such repairs the openings are carefully trimmed down plumb from the surface to an even depth, the whole is then thoroughly cleaned and given a light coating of a mixture of hot pitch and creosote oil and filled with 1-in. material, sufficient ½-in. being used to key the surface. The patch is then either rolled or well punned solid. In renewing surfaces it is well to deal with as long lengths as possible, the method adopted being the same as used in patching. In no case should the wear be allowed to extend below the finishing coats.

The life of a tar-macadam road varies in ratio to the intensity of the traffic, and has given best results in suburban roads. In the centre of the city, where subjected to heavy traffic, the results have not proved satisfactory. The author is, however, doubtful whether this is not due to defects in foundation rather than to failure in the wear of the tar-macadam surface crust.

Sett Paving on Existing Foundations.—The author has a considerable mileage of what may be termed second-class streets, through which a large amount of heavy traffic passes, paved with setts upon existing foundations. These setts are usually 6 in. deep, 3 in. broad, and from 5 in. to 7 in. in length, either of granite or whinstone. In most cases these streets were originally either ordinary macadam or boulder paving, and in consequence of the development of the district have been converted as indicated. In the case of a macadam road, sufficient depth is obtained for the new paving, and the old roadway trimmed off to the required contour. The setts are paved on a ¾-

in. bed of compo. formed of 4 parts of sea gravel to 1 of cement, and joined with a grout of 3 parts of sharp sand to 1 of cement. In the case of replacing boulder paving with setts the same method is adopted, with the exception that the setts are frequently bedded in the sand from which the boulders are taken, and grouted in cement. This class of carriageway forms a very serviceable and economical roadway, and although not having the appearance of better-class paving, provided the foundations are suitable, will withstand very considerable traffic. This paving, however, suffers considerably under traction engine traffic.

Sett Paving on Concrete Foundations.—In main thoroughfares and important streets traversed by heavy traffic of all descriptions, sett paving on concrete foundations is found the most serviceable. The concrete bed should be from 6 in. to 9 in. in depth, varying according to the subsoil; and having regard to the development of heavy self-propelled traffic, the author is inclined to advise that in no case should the concrete be less than 9 in. in depth. As mentioned before, the stone for sett paving is specially tested and selected, the requirements being a tough stone which at the same time will not become unduly slippery under horse traffic.

The standard size of setts used in Belfast is 4 in. square on head and 6 in. in depth, truly dressed on all surfaces, so that the setts can be paved on either end; the setts must be squared and dressed to the exact measurement (4 in. by 4 in.), and the variations in depth must not exceed ¼ in. The 4-in. sett on the surface affords greater foothold for horses, while, as compared with cubes, the extra 2 in. depth in the sett secures greater power of resistance to the rolling action of the traffic and breaking of the bond. The setts are paved upon a 1-in. bed of compo. formed of 4 parts of gravel and 1 part of cement, and again grouted with compo. of the same strength. Seven days are allowed for the jointing to set before the traffic is permitted to pass over the new paving.

The camber of a sett-paved roadway should not be greater than 1 in 50. In some cases the sett paving is grouted with a mixture of pitch and tar. This has the advantage of allowing the traffic to pass over the roadway as soon as the jointing has become thoroughly hardened. With properly selected stone this form of pavement will last under the heaviest traffic for fifty years, the setts during that period being once repaved with the lower ends upwards. At the present time there are in Belfast several heavy-trafficked streets near the quays which have been laid between forty and fifty years. Beyond this repaving, such repairs as are necessary cost on an average slightly less than one cent per square yard per annum.

Natural Asphalt, Hardwood and Softwood Paving.—Where sett paving is found undesirable owing to the noise caused by the traffic, natural asphalt, hardwood or softwood paving may be found suitable.

For heavy traffic a coating of 2-in. asphalt should be laid, and care taken in spreading where jointing up to asphalt already hardened to thoroughly make good the jointing in order to prevent fractures appearing in the road after the work has been finished. This form of roadway is usually laid and maintained by various companies who specialize in this material. The camber of an asphalt road should not exceed 1 in 50.

Wood paving, like sett paving, is laid upon a bed of concrete, and, like asphalt, the surface of the concrete is truly floated in cement to correspond with the finished contour of the roadway and the wood blocks directly laid on the cement surface.

The sizes of wood blocks as laid in Belfast are 9 in. by 4½ in. by 3 in. All blocks must be of thoroughly well-

Table No. 1.

Table Showing the Comparative Cost of Various Classes of Road Surfacing, Having Regard to First Cost, Capital Charges, Where Such May be Included, and Cost of Maintenance, Cleansing, and Renewals per Square Yard per Annum for a Period of 20 Years.

Surface Material	Average Life Years	First Cost per sq. yd.	Capital Charges per annum	Maintenance per sq. yd. per annum	Cleansing per sq. yd. per annum	Renewals		Total Cost per sq. yd.		Remarks
						Average cost per sq. yd per annum	Total Cost per sq. yd. for 20 years	Per Annum	For 20 years	
Water-consolidated Macadam (on existing foundations)	Variable	See Maintenance	Nil	4c. to 24c.	2c. to 18c.	See Maintenance		6c. to 42c.	$1.25 to $8.75	All charges paid for out of revenue
Tar Macadam (on existing foundations)	6	$ .50 to $1.12	Nil	2c. to 6c.	2c. to 7c.	2·8c. to 6·3c.	$ .58 to $1.30	9·2c. to 29⅔c.	$1.90 to $5.15	
Sett Paving (on existing foundations)	15	$1.87	Nil	4c.	6c.	3·2c.	$ .62	22c.	$4.58	
Sett Paving (exclusive of concrete foundations)†	*40	$2.25	15c.	1	7c.	—	—	23.2c.	$4.83	*The first cost is entirely paid out of capital in 20 years' period, remaining 20 years free of all capital charges
Natural Asphalte (exclusive of concrete foundations)†	10	$2.25	26c.	12c.	4c.	—	—	42c.	$8.73	First cost and renewals paid out of capital
Hardwood (exclusive of concrete foundations)†	15	$3.00	25c.	6c.	8c.	—	—	39c.	$8.12	Do.
Softwood (exclusive of concrete foundations)†	12	$2.25	22⅓c.	8c.	9c.	—	—	39⅓c.	$8.20	Do.

†9in. concrete foundation, including excavation, &c., costs $1.50 per square yard.
To repay capital charges in 20 years means an additional 11⅗c. per square yard per annum.

seasoned wood, free from shakes or other defects, and cut to exact sizes by machinery. In the case of softwood blocks creosote oil is forced into the blocks under pressure. Not less than 10 lb. of creosote oil per cubic foot of timber must be absorbed during the process. All blocks are examined and passed by the corporation inspector before being creosoted, and the inspector must also satisfy himself that the specified amount of creosote oil has been absorbed by the timber. Hardwood blocks, before being laid, are dipped to a depth of ½ in. in a mixture of pitch and tar or creosote oil, and an expansion joint left on either side alongside the curb to allow for the expansion of the wood when the roadway becomes moist. The width of expansion joint allowed is approximately one-ninetieth the width of the paving. To prevent the space being filled with dirt the joint is loosely closed in with puddled clay.

The author's experience in the case of hardwood paving block has been that the expansion and contraction is greater and more difficult to deal with than in the case of softwood.

Both cement and pitch have been used for grouting wood pavement, and in spite of the great advantage that pitch has over cement in allowing the immediate use of the road as soon as the surface has been thoroughly grouted, the author believes, especially in regard to hardwood, that cement grouting gives a very much more satisfactory result as regards the smooth wearing of the surface, particularly after some years' wear, than does wood pavement grouted with pitch. In some instances the pitch mixture, probably owing to its not having been sufficiently hard, with the vibration of the traffic in hot weather, has worked downwards and found its way under the lower surfaces of the blocks, thereby raising individual blocks above the normal surface level.

To finally determine the relative merits, a roadway in which the traffic is uniform from one end to the other was selected and paved with Jarrah wood blocks in May, 1907, one half with pitch grout, the second half with cement grout, and careful observations have been made since. For the first three years no difference was noticeable. At the end of the fourth the difference was so extremely slight that a person would not have noticed the change without having his attention called to the difference. At the end of the fifth year the change was more apparent. At the present time, although the section of the roadway grouted with pitch is in very good order, it is distinctly more uneven than the cement-grouted section on which the youngsters of the neighborhood disport themselves on roller skates when they are able to avoid the attention of the police.

As regards repairs, hollows appearing in the surface are mainly due to defective or soft blocks; these are cut out and sound blocks inserted with as little delay as possible. A stock of old blocks is kept for this purpose gauged to various depths, so as to fit in with the actual depth of the wood paving at the time that the repairs are required. No very serious difficulty has been experienced in Belfast in summer weather in regard to open joints, but on hot days a special water service is given to all wood-paved roadways. The gravel used for gritting the surface is specified to pass a ½-in. screen, the stones being rounded and about the size of peas.

Statistics.—A large amount of care is taken in the compilation of records as to the qualities of materials used in the construction and maintenance of roads, and also as to the maintenance cost of each road individually.

Every water-consolidated macadam road in the city is scheduled in a macadam road journal, and all charges, both in regard to materials and workmanship, are returned weekly from each district and posted in this journal against the respective roads on which the work has been done. By this means an accurate record is maintained which proves of the greatest importance and use in determining, not only the merits of any special materials or methods that may be employed, but also if the cost of the maintenance of the existing surfaces is the most suitable and economical having regard to the traffic each road is called upon to bear.

With regard to the construction of tar-macadam roads, for some years a register has been kept in which is recorded:—

(1) The date when the tar-macadam road was first laid.

(2) Particulars of the original roadway.

(3) Superficial area dealt with.

(4) Thickness of tar-macadam surface.

(5) Tonnage of materials delivered.

(6) Number of square yards per ton of each size of tar-macadam used.

(7) Cost of scarifying and preparing foundations, including removal of materials.

(8) Value of old materials.

(9) Total net cost of preparing foundations, with cost per square yard.

(10) Cost of laying tar-macadam under the following heads: (*a*) Labor, (*b*) cartage, (*c*) materials, (*d*) miscellaneous charges.

(11) Total net cost of the work.

These items are again worked out to cost per square yard. The condition of the weather during the progress of the work is also recorded, and any special remarks entered that may be of future value. Reference to this register from time to time has been found of the greatest value in investigating and analyzing the behavior of the various road surfaces. A careful record is also made of all repairs done to each road, so that the actual maintenance charge in each case may readily be ascertained.

Cleansing.—In connection with road maintenance, it must be emphasized that it is of the utmost importance that every care and attention should be given to the cleansing of road surfaces, as, if cleansing is not done with due regard to the proper requirements of the road, a very large amount of waste and damage will accrue. This especially applies to water-consolidated macadam roads. All surplus mud should be removed without delay. An undue amount of sweeping, especially in dry or frosty weather, or on a newly made road, causes serious damage by the removal of the binding material in the road surface.

The greatest care should also be exercised in the cleansing of a newly paved street so that the jointing material is not disturbed by the operation; also in the case of wood pavement it is of great importance that a thorough and systematic cleansing should be maintained, the refuse being removed either to orderly bins or in barrows. It will be found necessary at times to wash the surface of the roadway, this being usually done at night, and, as has already been mentioned, the wood pavement should be thoroughly watered during hot or windy weather to protect it from the effects of shrinkage.

In order to indicate the most suitable form of road surface from an economic standpoint, Table No. 1 gives the comparative cost of various classes of road surfacing, having regard to first cost, capital charges, where such

may be included, and cost of maintenance, cleansing and renewals per square yard per annum for a period of twenty years.

Owing to fluctuations in the price of materials and wages due to local conditions, maximum and minimum figures are given for water-consolidated macadam and tar-macadam roads. Should, in exceptional cases, the range provided not be found sufficient, other figures may be supplemented and conditions ascertained.

In comparing these figures, which represent present-day costs, with those of road surfaces of a more permanent nature, allowance should also be made for the advance in price of materials and wages which must take place during the period under consideration. Table No. 2 gives the cost per mile per annum of a road 18 ft. wide, surfaced with the materials scheduled in Table No. 1, and more clearly indicates the comparative maintenance expenditure involved.

Having carefully considered the question of road maintenance in respect to various surfacing materials from a purely economic standpoint, it becomes necessary to consider the probable future developments, not only in respect to a particular road, but also to the district through which it passes, and the requirements in regard to same. One factor which the author feels at times hardly receives the attention it deserves is the direct saving of wear and tear on all classes of vehicular traffic due to the substitution of a suitable road surface in the place of one that has become effete, and also to the saving on adjoining road surfaces by the diversion of traffic on to the new road. Again, the hygienic qualities and noiselessness of the materials selected, in relation to the traffic and needs of the locality, must be carefully weighed. The values of these factors cannot be expressed by any mathematical formulæ, but nevertheless on the accuracy of the conclusions arrived at largely depends the success or failure of a general system of road maintenance.

Table No. 2.

Table Showing Cost of Maintenance per Square Yard and Cost per Mile per Annum of a Roadway 18 Feet in Width.

Surface material.	Cost per sq. yd. per annum.	Cost per mile per annum of roadway 18 ft. in width.
Water-consolidated macadam on existing foundations	6 to 42c.	$642 to $4,497.00
Tar macadam on existing foundations .....9.2 to 24.7c.		$985 to $2,642.60
Sett paving on existing foundations	22c.	$2,355.00
Sett paving exclusive of concrete foundations..	23.2c.	$2,484.00
Natural Asphalte, exclusive of concrete foundations	41.8c.	$4,493.50
Hardwood, exclusive of concrete foundations..	39c.	$4,173.50
Softwood, exclusive of concrete foundations..	39⅓c.	$4,212.00

9 in. concrete foundation, including excavation, etc., at 12 cents per square yard (first cost), repayable in 20 years = $1,080.40 per mile.

Table Showing Relative Merits of Various Road Surfacing Materials in Respect to Ease of Haulage, Noiselessness and Hygienic Qualities.

Ease of haulage.	Surface material.	Noiselessness.	Hygienic qualities.
6	Water-consolidated macadam	1	5
3	Tar macadam	3	2
5	Sett paving on existing foundation	5	4
2	Sett paving on concrete foundation	6	3
1	Natural Asphalte	4	1
4	Hardwood and softwood	2	6

FUNCTIONS OF THE NON-BACTERIAL POPULATION OF THE BACTERIA BED.*

By James Crabtree, B.Sc., A.I.C.

EXPERIMENTS on the part played by protozoa in soils, have been extended to sewage disposal beds, and have shown the decided effect which removal of the fauna of the bacteria bed has upon its capacity, a bed with no (or very little) animal population "making up" much quicker than a bed with a normal fauna.

This absence of fauna can be the only cause of this observed difference in capacity, as any effect caused by bacteria would be in the opposite direction; for, since the number of putrefying bacteria (those growing on nutrient gelatine) was generally greater in the partially sterilized bed than in the control, the tendency would be for a greater resolution of solid matter in the toluened bed than in the control, with a corresponding increase in the capacity compared with the control. This is quite contrary to the observed results, which showed a decrease in the toluened bed compared with the control. The difference can, therefore, only be assigned to the animal population, which in some way keeps the bed "open."

Exactly how this is caused can not yet be said—whether the organisms actually digest the particles of solid matter, or whether the material is taken up to form the tests or shells of rhizopods, etc., thus modifying the nature of the deposit and allowing the water to run off more freely. There is probably a good deal of actual digestion taking place—at any rate, of the more easily resolvable precipitated colloidal matter. To the eye, however, the most striking difference in the deposits on the bed media is in the physical character rather than the amount, the deposit in the toluened bed being, as before stated, much more spongy and less granular than in the normal bed. That there is a difference in amount is shown by the following estimation made at the end of the experiment, on a control bed, A, and two beds B and C, partially sterilized by toluene.

Amount of deposit per 1,000 c.c. bed medium (obtained by brushing off into water the deposit from 50 c.c. medium, taking an aliquot portion and evaporating dry): A bed, 19.2 gs.; B bed, 20.2 gs.

According to these figures there is more deposit per unit capacity of bed in the bed deprived of its animal population.

How much of the difference in capacity is caused by difference in character and difference in amount of de-

*From a paper read at the Exeter Congress of the Royal Sanitary Institute.

posit must be left to the future to decide. The fact remains, however, that the animal population does a good work in keeping the bed medium "open," and, from this standpoint, are very desirable inhabitants of the bacteria bed.

Outside the effect caused by difference in capacity, what is their connection with the actual purification processes taking place in the soluble constituents of the sewage? A consideration of the results obtained leads us to say that it is probably very little.

The improvement in the effluent on a toluened piece of soil, and a similar improvement in a toluened bed outlined in the above experiments may, in our opinion, be explained away by the difference in capacities produced in the beds. The fact that in a toluened bed we get a greater number of bacteria capable of growing on gelatine seems to indicate that we should get a greater purification in that bed. The experiments with beds A and C (which did not differ in amount and nature of surface deposit, but where C contained a greater number of bacteria than A) do not support this idea, for C gave a worse effluent than A. For, after all, a comparison of the counts on nutrient gelatine does not of necessity indicate the relative proportions of those bacteria bringing about the purification in the respective beds. Bacteria growing on gelatine are largely putrefactive, while the processes going on in the bacteria bed are largely processes of oxidation.

Müller, investigating the reduction of bacteria in water samples due to protozoa, finds that although a reduction takes place among the bacteria capable of growing on gelatine, those growing on Heyden agar are practically unaffected. His conclusions are that the protozoa prey only on bacteria foreign to the water (e.g., B. coli, B. Typhosus, and many putrefying bacteria), while the normal population goes untouched.

STEEL VS. WOODEN SIDEWALK FORMS.

BEFORE the advent of steel forms, concrete for sidewalks, curb, and curb and gutter was molded by means of wooden forms. The contact of wet concrete, however, tends to warp the wood out of shape, besides the nailing and staking necessary in setting them up makes moving difficult without danger of breaking or splitting, which shortened the life of the forms. The skilled labor necessary, time required in setting, and cost of lumber for this work, make these items enter largely into the cost of the job. Metal forms of various types have been designed to overcome this difficulty by securing greater durability of forms, more uniform work, besides saving labor, cost and time required to complete the work.

In Municipal Engineering, Mr. Chas. H. Allison, describes their successful use and gives a number of pointers gained from his own experience with them.

No type of concrete construction is better adapted for the use of steel forms than concrete sidewalk, curb and combined curb and gutter. Although steel forms are more expensive than wood in first cost, their advantages are so many that they are now being used to a large extent in the work of this sort.

Sidewalk side rails are used in constructing crosswalks by having 6 or 8 division plates shaped to suit the cross sectional crown of the walk. By the use of two adjustable rigid side-rails, these forms can be set to build a crosswalk for any width of street. The all-steel curb forms are built for a curb 20 inches deep, 6 inches wide on top and 8 inches on the base, in 12-foot sections, with provision for templates at intervals of 6 feet. The side rails are similar to those used for sidewalks. Templates can be made to conform to any desired specifications.

The all-steel curb and gutter forms are made similar to the combination sidewalk and curb forms, with 3-inch flanges. One wide side rail is used to form the back and a narrow one on the front. With these forms a steel side rail is used to mold the face of the curb and is held in position by a metal arm or brace attachment. These forms are also made for curved sections. Division plates are made to be used with plank side rails for curb and combination curb and gutter.

The division plates used in the forms which the writer has been using are entirely different from those found in other systems as they can be removed by one man without disturbing the side rails and without the use of a hammer. They are connected by merely dropping them in their proper places and no wedges, keys, bolts or moving pivots are required. These division plates are to be had in all lengths up to and including 6 feet and in the construction of a 12-foot walk it is only necessary to double the 6-foot plates and in the building a 10-foot walk it is only necessary to double the 5-foot plates.

These division plates do not project or extend above the top or beyond the outside of the side rails. They are perfectly smooth between the side rails and have tapering slots which will not bind when the plate is drawn from the concrete. One of the particular advantages of this system of forms is that there are no intermediate slots in the division plates to corrode and tear up the concrete when the plates are withdrawn.

The side rails, which are connected together without the use of keys, wedges or bolts, are 12 feet in length and are made of a special shape, comprising three right-angle bends, thus making the construction most rigid and durable. These rails are so made that the top surface is free of any obstruction which would interfere with the free passage of rodding-off tools. They are easily adjustable, thus enabling the workmen to place the forms in any odd space without using wood to fill in. These side rails are so made that it is a simple matter to make a block of any desired size.

It is a very simple matter to so adjust 100 feet of these sidewalk forms to be used as 100 feet of curb and gutter forms; all that is necessary is an additional use of 16 curb and gutter templates.

It is a very easy matter to construct 350 feet of sidewalk per day with the use of but 100 feet of these forms. They are simple to place and there is no toggle arrangement to oil and the division plates can be removed before or after finish is applied.

September 15th and 16th are the days of the sixth general Annual Assembly in Calgary of the Royal Architectural Institute of Canada. According to the programme, the two days are well filled, and several of the papers to be presented deserve special mention. A lecture on Ferro-Concrete will be given by Mr. F. Goldie Engholm, A.M.I.C.E., of Vancouver. Prof. E. Brydone-Jack, Department of Civil Engineering, Manitoba University, will also present a paper. The headquarters of the Institute during the assembly will be at the Public Library, Calgary.

STEEL PRODUCTION IN THE UNITED STATES.

THE Bureau of Statistics of the American Iron & Steel Institute has received from the manufacturers statistics of the production of all kinds of steel ingots and castings in the United States in 1912. The production of ingots and castings by all processes reached the remarkable total of 31,251,303 gross tons, against 23,676,106 tons in 1911, an increase of 7,575,197 tons, or almost 32%. The remarkable point is that while the production of steel in 1911 exceeded that of pig iron by a small amount—26,559 tons—in 1912, the excess was no less than 1,524,166 tons. As there were no large stocks of pig iron on hand at the beginning of 1912, it is evident that the openhearth furnaces must have used a large proportion of scrap in making steel last year.

The total production of steel of all kinds in 1912 is given below:

	1911,	1912,			
	Total.	Ingots.	Castings.	Total.	%
Bessemer	7,947,854	10,259,151	68,750	10,327,901	33.0
Acid openhearth .	912,718	712,371	426,850	1,139,221	3.6
Basic openhearth.	14,685,932	19,197,504	443,998	19,641,502	62.9
Crucible	97,653	100,967	20,550	121,517	0.4
Electric	29,105	14,147	4,162	18,309	0.1
Miscellaneous ..	2,844	542	2,311	2,853	...
Total	23,676,106	30,284,682	966,621	31,251,303	100.0

The total increase in 1912, as compared with 1911, was 7,575,197 tons, or 32%. The increase in basic openhearth steel in 1912 was 4,955,570 tons, or 33.7%; in acid openhearth, 226,503 tons, or 24.8%. The gain in bessemer steel was 2,380,047 tons, or 29.9%. The production of bessemer-steel ingots was practically all in standard converters; that of castings was from tropenas and other modified forms of converters. No basic converters are in use in the United States. The make of openhearth steel in 1912 was over twice that of converter.

Included in the 19,641,502 tons of basic openhearth-steel ingots and castings produced in 1912 are 1,438,654 tons of duplex steel ingots and castings which were made from metal partly purified in bessemer converters and finally purified in basic openhearth steel furnaces. This steel was produced by seven works, four being in Pennsylvania, one each in Maryland, Alabama and Illinois.

The production of crucible steel showed a gain of 24% over 1911; that of electric steel, however, was considerably less than in 1911 and 1910. The make of crucible steel was exceeded in two previous years.

Steel Production for Ten Years.—The total make of steel of all kinds in the United States for 10 years past is given in the following table:

	Bessemer,		Openhearth,		Crucible, etc.,		Total,
	Tons.	%	Tons.	%	Tons.	%	Tons.
1903 ...	8,592,829	59.1	5,829,511	40.1	112,238	0.8	14,534,078
1904 ...	7,859,140	56.7	5,908,166	42.6	92,581	0.7	13,859,887
1905 ...	10,941,375	54.6	8,971,376	44.3	111,196	1.1	20,023,542
1906 ...	12,275,830	52.5	10,980,413	46.9	141,893	0.6	23,398,136
1907 ...	11,667,549	49.9	11,549,736	49.5	145,309	0.6	23,362,594
1908 ...	6,116,755	43.6	7,836,729	55.9	69,463	0.5	14,023,247
1909 ...	9,330,783	38.9	14,493,936	60.5	130,302	0.6	23,955,021
1910 ...	9,412,772	36.1	16,504,509	63.3	177,638	0.6	26,094,919
1911 ...	7,047,854	33.5	15,508,650	65.9	120,602	0.6	23,676,106
1912 ..	10,327,901	33.0	20,780,723	66.5	142,679	0.5	31,251,303

The growth of production in the 10 years has been almost wholly in openhearth steel. Bessemer or converter steel reached its maximum in 1906 and has declined since then, its proportion of the total falling from 59.1 to 33%. Openhearth steel ran bessemer closely in 1907; exceeded it in every year since that, and in 1912 its output was more than twice that of bessemer steel.

Alloy Steel.—The following table gives the approximate production by processes of steel treated with ferro-vanadium, ferro-titanium, ferro-chrome, nickel and other alloys:

	Ingots.	Castings.	Total.
Bessemer	159,427	18,814	178,241
Acid openhearth	85,188	75,590	160,778
Basic openhearth	408,007	5,095	413,102
Crucible	27,553	3,208	30,761
Electric, etc.	9,217	402	9,619
Total	689,392	103,109	792,501

In 1912 there were 143 works which made some form of alloy steel. This alloy steel constituted 2.5% of the total make. A large part of this steel was used in the manufacture of rails.

Number of Steel Plants.—At the close of 1912, there were 30 plants equipped to make steel by the standard bessemer process, 35 plants by the tropenas process, and 37 plants by other modifications of the standard bessemer process, while at the close of 1911, 29 plants were equipped to make steel by the standard bessemer process, 29 by the tropenas process, and 31 by other modifications of the standard bessemer process. There were no bessemer plants building at the close of 1912, but 13 plants were projected.

At the close of 1912, there were 182 complete openhearth-steel plants, of which 157 were active during the year and 25 were idle. Of the total 113 were equipped to make basic steel, of which 101 were active during the year and 12 were idle, and 96 were equipped to make acid steel, of which 77 were active and 19 were idle. Some of the plants were equipped to make both basic and acid steel. Six plants were being build on December 31, 1912. On the same date work had been suspended upon three partly erected plants. In addition, five plants were projected. In 1912 four plants made steel by the cementation and other minor processes; in 1911 five plants were active. On December 31, 1912, one plant for the manufacture of steel by a special process was being built in the State of Washington.

The total number of steel plants of all kinds in existence at the close of 1912 was 306, which includes one openhearth plant in the Panama Canal Zone. This total is an increase of 24 during the year.

In connection with the 1912 production, Engineering News published an interesting table a few weeks ago comparing the acid and basic outputs of Germany and the United States, which is given below:

	—United States—		—Germany—	
	Acid.	Basic.	Acid.	Basic.
Converter ...	10,327,901	.....	28,511	10,015,631
Openhearth ..	1,139,221	19,641,502	194,924	6,650,565
Crucible	121,517	.....	79,190	.....
Electric, etc. .	21,162	.....	74,177	.....
Totals	11,609,801	19,641,502	535,802	16,666,196
T'l all kinds.	31,251,303	.....		17,301,998
Proportion of steel to pig iron		105.1	.....	96.8

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of
CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, RAILROAD, MINING, MUNICIPAL HYDRAULIC, HIGHWAY AND CONSULTING ENGINEERS. SURVEYORS, WATERWORKS SUPERINTENDENTS AND ENGINEERING-CONTRACTORS.

Present Terms of Subscription, payable in advance
Postpaid to any address in the Postal Union:

One Year	Six Months	Three Months
$3.00 (12s.)	$1.75 (7s.)	$1.00 (4s.)

Copies Antedating This Issue by More Than One Month, 25 Cents Each.
Copies Antedating This Issue by More Than Six Months, 50 Cents Each.
ADVERTISING RATES ON APPLICATION.

THE LONG SAULT RAPIDS POWER SCHEME.

One would imagine that the history of the project of the Long Sault Development Company, in so far as it pertains to Canada, has reached its closing chapter. The company's proposal involves the erection of a 3,800-foot dam between Barnhart Island and the north-easterly end of Long Sault Island in the St. Lawrence River, and another, 1,450 feet in length, adjacent to lock 20 of the Cornwall Canal, on the Canadian side, thus requiring the construction of a new channel with a new canal at that point. Its proposal includes the generation of 500,000 h.p. of electrical energy on the American side and of 100,000 h.p. on the Canadian side. The company's many and varied assurances that the development was just what Eastern Ontario needs, were commented upon in *The Canadian Engineer* of October 24, 1912, and were accompanied by a note of caution, toward the safeguarding of Canada's interests.

It is now six years since the company obtained a charter in New York State authorizing it to construct dams and other works at Long Sault Island for the development of electrical energy and the improvement of navigation, but not across the international boundary "unless consented to by the Dominion of Canada." In the meantime a Canadian charter has been diligently and persistently sought, for the widening of the whole project. The granting of it has been pending a report, after most thorough investigation, from the Commission of Conservation. Meanwhile the New York charter was repealed a few months ago, and a special application was presented to the United States Congress, also pending.

The Commission of Conservation has just issued its report, expressing strong disapproval of the scheme. The report is a complete review of the question, and presents no vague impressions. The outcome of it should be a discountenancing of the power scheme by the Dominion Government. It is not for the reason that the company resorted to improper tactics in endeavoring to create an impression in Ontario favorable to the granting of a Canadian charter; or that the company is a small part of a strong financial and commercial organization included in which is the St. Lawrence Securities Company, and back of it the Aluminum Trust. Nor it is because the United States franchise has been discontinued. The commission's report places its finger on the vital point when it emphasizes the likelihood of the proposed development placing enormous difficulties in the way of the imminent enlargement of Canadian navigation facilities. Deeper navigation upon the St. Lawrence will forthwith command the attention of the Dominion Government, and a free hand in the undertaking of such an enterprise must be maintained.

The proposed diversion of water by the dam between the Long Sault Island and Barnhart Island would take from the main navigable channel over one-third of its water. The effect of such a diversion of water from the navigable channel is impossible to estimate. It can, however, be stated with centainty that the navigability of the channel would not be improved by such diversion. The construction of the dams in question would result in compelling navigation (other than by the Cornwall Canal) to follow a new route known as the South Sault Channel. Experienced navigators are of the opinion that this route would be much inferior to that now followed.

From the point of view of benefits accruing to Canada from the proposed power development, the report

dispenses with the alleged advantages in the following way:—

"Looking at the whole scheme, it does not appear that any serious attempt can be made to show that Canadian requirements or Canadian interests are an appreciable factor in the plans of the company. The plans contemplate the absolute monopolization of the whole power available from the rapids with a minimum consideration of Canadian interests.

"No market exists at the present time on the Canadian side for the power proposed to be developed, or for any appreciable portion thereof. When any large quantity of power is required in the territory tributary to the proposed works it can be otherwise provided. Should the time come when further power is required by Canadian interests, and the placing of a dam across the St. Lawrence River is determined upon, one-half of the power to be generated thereby will belong by right to Canada and should be permanently retained for Canadian use without exception or qualification."

HAMILTON'S RAILWAY PROBLEM.

Readers will remember our recent reference to the plan which the city of Hamilton is working out in an endeavor to have the railways adopt a common route through the city, and to the dissenting stand which the Toronto, Hamilton and Buffalo Railway is taking. An article beginning on page 411 of this issue goes into interesting detail concerning the whole situation.

It is quite clear that the solution of this problem is going to play an important part in the future expansion of Hamilton. The city is destined to increase in size by reason of its peculiar geographical situation and in spite of the same. Its present population may double in the next 25 years. At any rate, the expansion is well under way, and no more appropriate time than now is likely to present itself for the complete straightening out of the question of railway right-of-way.

Conditions have changed since the T. H. & B. was first granted its right-of-way over the streets of the city. Public opinion against level crossings has developed generally, and the local trend of residential growth toward that section of the city would render it impossible if the railway were seeking to-day the right-of-way it secured twenty years ago. To what extent should further development of its present system, in the matter of a station and trackage extensions, be permitted, is a live factor with which the civic authorities, bent as they are upon an entire revision, must contend.

The refusal of the T. H. & B. to consider the city's plan to unite the railways on a common right-of-way, and in a union station, is largely based upon the adaptability of the location of its present station for passenger traffic. Granting this, alternative plans have been forwarded, dealing with elevation or depression of tracks. Of the two plans, as outlined in the article, while cost and questions of operation are in favor of the elevation project, the depression plan is more consistent with the present condition of entrance from the west, as the tracks are already depressed from the city limits to Park Street. The advantages which the city will thereby derive are beyond question, and the plan should be vigorously pushed forward.

CANADIAN NATIONAL EXHIBITION

Since its inception in 1879, the Canadian National Exhibition has grown—wonderfully. It has kept well in step with the Dominion's march of progress, and the inter-relation between the two has been close. Through its park of 264 acres, its buildings of stone, brick, concrete and steel, costing $2,225,000, its half a million feet of exhibit floor space, and its "million mark," the value of the Exhibition to Canada may be estimated.

President Kent has announced a proposed expenditure of $50,000 in improving the agricultural department of the Fair. This will incite a keener interest in the live stock exhibits, and will be money well spent.

An inspection of the marked indications of the rapid development of Canadian industries, particularly of machinery and processes, creates the impression that the above extension should shortly be followed by added accommodation in this department as well. The great Fair is built up by the co-operation of innumerable units, many of which are each the result of large annual expenditure. Many concerns have cheerfully spent thousands of dollars annually on exhibits that have not seen the inside of these great buildings, but are tented in some necessarily obscure location. This should be remedied. Machinery Hall should be duplicated, in order that these exhibits receive the housing they deserve. Otherwise, firms cannot be expected to retain their co-operative spirit in making the Exhibition what is is.

The Canadian National Exhibition is very deserving of attaining the million mark in attendance. The achievement, considering weather conditions at this time of year, and also the pre-occupation of farmers in harvesting, shows that it is receiving world-wide recognition and that Canada is unknown nowhere on the globe. But to fulfil its function, as an Exhibition, it should have more accommodation for the machinery men.

EDITORIAL COMMENT.

It is anticipated that about 1,100 miles of colonization roads will represent Ontario's progress in this respect this season. The north country is being webbed with good roads at a rapid rate and by another season the work of construction will have so far advanced that a settlement campaign on a large scale may be carried on. Mr. G. W. Bennett, Provincial Superintendent of Colonization Roads, states that the number of men employed ranges between 4,500 and 6,000. Satisfaction is being derived from doing the work by day labor, and no part of it is under contract this year.

* * * *

The navigability of the Saskatchewan River is being investigated by the Dominion Government, and the engineer in charge of operations, Mr. L. A. Voligny, reports that the river will greatly enhance the shipping facilities in conjunction with the Hudson Bay Railway from Le Pas. In many parts of the river the channel is sufficiently deep and for miles little extra work will be necessary to put it into shape. Eventually the waterway may extend from Edmonton to Winnipeg, which, if accomplished, will go a long way to reduce shipping rates.

STREET AND PAVEMENT CONSTRUCTION

ESSENTIAL TO PREMISE NATURE OF FUTURE WEAR—VARIOUS PAVEMENTS IN USE FOR URBAN TRAFFIC, AND THEIR CHARACTERISTICS —THE STREET RAILWAY SYSTEM AND THE RAIL IT SHOULD USE

By A. F. MACALLUM, C.E., A.M. Can. Soc. C.E.,
City Engineer, Hamilton, Ont.

THE first necessary function of a paved roadway is to supply a hard, smooth, and durable surface upon which the vehicular traffic of the town may be conducted with the least expenditure of energy; other considerations being cheapness, and low maintenance. It should also be sanitary, and not slippery in any kind of weather. This would give an ideal pavement that at present does not exist, for a pavement ideal in one location would not be in another, although it has been suggested that the general requirements in all cases would be the same. This does not naturally follow, for in one case low first cost and low maintenance cost may be the first consideration, while in another case ease of hauling and lack of slipperiness may govern, and a third case noiselessness and sanitariness may overbalance all other considerations.

In the following table different authorities give relative values of the various qualities of an ideal pavement:—

	U. S. Bulletin.	Tilson.	Baker.
First cost—Cheapness ..... Maintenance cost—Cheapness.	14	14	15
Durability	20	21	..
Ease of Maintenance	10	10	20
Ease of Cleaning	14	15	10
Low Tractive Resistance	14	15	10
Non-slipperiness	7	7	5
Sanitariness	13	13	25
Noiselessness Acceptability	4	..	15
Favorableness to travel	4	5	..
	100	100	100

It will be noted that while the United States Bulletin and Tilson agree closely, a considerable variation exists between them and Baker. Apparently they had in view pavements subject to heavy travel, while Baker considered a residential type of pavement.

Using values for this from the present costs of different pavements under conditions where the pavement proposed will exist, it is possible for the engineer to select the proper pavement for any particular case without bringing in the personal equation.

The first question that arises when a street is to be paved is what will be the probable quantity and character of the traffic to which it will be subjected. Although it is an obvious fact that a street in a business section should be treated differently from one in a residential section, yet, it is not done so in many cases. In the first case the paved portion of the roadway should be made as wide as the boundaries of the street will permit, while in the second a width of twenty-four feet (24′) is quite sufficient. Any additional width is more than wasted because this additional width of paved roadway will increase in the ratio of its width the cost of maintenance, cleaning, sprinkling, and cuts for house services. It may be objected that carriages and other vehicles could not turn around in a street twenty-four feet (24′) wide. While many could not, yet with blocks of the usual length such vehicles could go around the block. It is a very moderate statement to say that many thousands of dollars have been wasted in this country by making the pavements and roadways in residential districts unnecessarily wide.

Where street railway tracks exist through paved streets they are a serious menace to the durability of the pavement. Unless the paved area outside the tracks is of considerable width (say 18 feet) the traffic is so concentrated in narrow strips on each side of the tracks as to many times increase the traffic per foot of width on these strips with the consequent wear and tear to the pavement. It is also impossible to maintain any kind of a pavement alongside a poorly constructed railway track.

When a street is about to be paved it is not always possible to keep to the existing grade of the roadway to obtain the best grade for the desired pavement. It is doubtful if there is any other municipal improvement that will raise a louder howl of indignation from property-holders than the grading of a street for a pavement. The average property-holder considers only the street directly in front of his property, and believes firmly that the rest of the street should be made to conform with that regardless of drainage, ease of traction, and appearance. The stranger visiting a city for the first time may not remember the handsome buildings, but if the streets are bad he will never forget it.

Preliminary Works.—As water is the enemy of all pavements provision should be made in clay soils for proper drainage.

Every writer on pavements from Macadam to the present has referred to sub-drainage as the first essential to successful pavement construction. Where the sub-drainage is insufficient the underside of the pavement is always damp with the inevitable result of deterioration, and a tendency of the pavement to settle from its normal shape and grade. It may be assumed that any of the modern and practically waterproof forms of pavement now in use will have the sub-soil beneath it dry providing no water percolates from back of the curb which can be prevented by means of small tile drains beneath the curb. If the sub-soil be gravel, or sand, giving natural drainage no artificial drainage is required.

Macadam.—This is not a pavement, but as it is low in first cost, quiet and satisfactory if properly constructed, and used only upon residential streets where the traffic is not heavy. It is a good first pavement in a district not fully built up where there will be considerable tearing up of the roadway for house services.

*Read at the fifteenth annual meeting of the Ontario Municipal Association, Toronto, August 28th and 29th.

The usual method adopted for constructing macadam roads is to dump the broken stone on the road and roll to the form of the road, putting a certain amount of binder on top and wetting. The result is generally an uneven surface and rapid erosion after traffic has been upon it for a short time. Very seldom are large stones placed on edge on a proper camber of foundation, as brought out by Telford, although by so doing it will stand heavier traffic. As in all pavements the roadway should be rolled before the stone is placed upon it to the proper camber, and not more than ten inches (10″) of stone placed before rolling with a fifteen (15) ton roller. This stone should be hard and not all of one size, although such a clause will be found in many specifications. Sufficient small limestone binder should be added and flushed and rolled until the voids are filled and the surface in the proper form. After two or three days the street may be opened for traffic. If it be desired to provide a practically waterproof and dustless macadam then after about ten days' time the roadway should be swept to remove loose material, and a distilled coal tar heated to a temperature of about 250 degrees Fahrenheit should be sprayed using about ¾ of gallon per yard, and immediately covering with about ¼-inch of sand, or stone screenings. After rolling once upon the following day a second coating of about ½-gallon per yard should be applied cold and again sanded. In about ten days' time the roadway will have the general appearance of an asphalt pavement, the penetration of the tar being from one to two inches.

The advent of the automobile has made necessary the protection of the macadam surface from unravelling, and removing of the binding material in the form of dust. Oils of various kinds have been in use for several years—more or less successfully. Crude petroleums which contain the largest proportion of pure asphaltum give the best results. The petroleums having a paraffin or naphtha base are useless as they will not bind besides making a greasy slime and having an ill odor. It has been a common thing for an official to whom all oils look alike to purchase carloads of oil of unknown quality, sprinkle it from watering cars instead of spraying in unrestricted quantity regardless of the road condition, or weather. As a consequence slimy mud has been caused by sudden rainfalls which forms an emulsion with the oil, and the oil has pooled in depression in the roadway. It is necessary for the roadway to be first swept clean, be thoroughly dry, and have the oil heated and applied upon warm days.

From plain macadam roads to oil and tar painted, and on to tar macadam is but a step. Some years ago in Hamilton tar macadam pavements were extensively laid and these were successful in some cases, but not in others. The failures were partly due to using a limestone which was not tough or hard enough, and partly through the variable nature of the coal tar supplied. If tar used be not sufficiently refined the light oils and ammoniacal liquors will disintegrate. If it be heated too much it becomes brittle and forms black dust. There are now tar preparations on the market which give a reliable uniform product. In every city having a gas works using various grades of coal the quality of crude tar from a given tank will vary. Even with the coal constant the tar drawn from the bottom of a full tank will often differ materially from that taken from the same tank when nearly empty. Most failures in using crude tar may thus be traced to the variable nature of the tar which would not have occurred by using tar refined to the proper uniformity.

The tar macadam pavements which failed as such in Hamilton were not, however, total failures. The pavements were levelled up with concrete and asphalt binder, and a sheet asphalt top placed on it at very small comparative cost and with excellent results. These tar macadam pavements cost from 97 cents to $1.06 per square yard.

By the use of asphalt instead of tar a suitable pavement may be secured. The asphalt is applied in either of two ways, by penetration or pouring, or by mixing, as in the case of the tar macadam just mentioned. Using the penetration method, and after the foundation course has been rolled, there is placed a wearing surface of two inches thick (after compression with a road roller) of stone passing a two-inch ring. If there is already a foundation of concrete, old brick, block or macadam of sufficient strength no other foundation course will be necessary. On this wearing surface of compressed stone no water should be used but with suitable distributors from one and a half to two gallons per square yard of an approved asphalt binder should be poured depending upon the character of the broken stone. This binder should have a temperature ranging from 300 to 350 degrees Fahrenheit, and applied when stone is dry. Stone screenings are placed then on top sufficient to fill all surface voids, and the surface again rolled until smooth and true to cross section. Approximately one cubic yard of this material will cover 50 yards of roadway surface. A squeegee coat of approved asphalt from ½ to ¾ gallons per yard is then applied, and again sufficient screenings and rolling when the roadway is open for traffic.

In the mixing method the 1½-inch stone is dried and mixed with asphalt at the plant at a temperature not less than 300 degrees Fahrenheit, and spread on the prepared foundation to a depth of three inches after compression with a roller while the mixture is still hot, however, and before rolling stone chips, or sharp coarse sand free from dust should be spread over the surface. It is important that the rolling be thorough, especially about manholes, etc. As for the penetration a squeegee coat is spread and re-rolled as in the previous method. By this latter method an asphalt plant either portable or stationary is necessary. The crown of these bituminous pavements should be flatter then for macadam; in fact should be about ½-inch per foot of width where the grade will allow as in cold weather, it is apt to be somewhat slippery. The average cost of macadam in Hamilton was 60 cents, and for bituminous pavements as described, the cost would be from 25 to 40 cents more.

From bituminous macadam we naturally drift into bituminous concrete, where the stone is varied in size from sand to stone one inch in size graded to have as few voids as possible. Under this head come proprietary pavements, as Westrumite Bitulithic, and Warrenite The ingredients are combined and mixed at the plant and spread about two inches thick upon the foundation which is usually of concrete roughened on the surface. The following mortar has been used successfully in Chicago:—

Bitumen	18.8%
Passing 200 mesh	11.0%
" 80 "	10.6%
" 40 "	36.6%
" 10 "	23.0%
	100.0%

In proper grading of the smaller constituents about as above a close firm pavement is secured, less care being necessary for the larger sizes, provided also, of course, that a good asphaltic cement is used.

These bituminous pavements will cost from 95 to 90 cents per square yard, not including the concrete base, and are not intended for streets upon which the traffic is heavy. It may be intense that in having a large amount of light or rapidly moving vehicles with occasional teaming of coal or building material, and still be an excellent pavement, but it will not stand the traffic on business streets in cities.

Street asphalt pavements are laid only in the larger cities in Ontario on account of the skill required in properly mixing at the plant. Another reason is that such a plant is necessary. The refined asphalt is softened with a heavy mineral oil in the proportions of about eighty-one to eighty-six parts by weight to nineteen to fourteen parts of flux, and this forms the asphaltic cement. This cement forms from 9½ to 11½ parts by weight of the asphaltic mixture which forms the wearing surface. Between the wearing surface and the concrete base is placed a binder of ½ to 1″ stone which holds the surface to the base.

A few years ago several cities in the United States, and one or two cities here, including Hamilton, laid pavements without the binder course, roughening the concrete base instead. While it was successful on some streets with very little traffic it failed on well-travelled streets by rolling on the base. It was found almost impossible to get a roughened base without projecting stones too deeply into the surface mixture, and as a consequence much of the base was made too smooth with the resultant rolling under traffic. In earlier pavements an open binder was used, but recently a binder much closer is used.

The asphalt surface is principally graded sand; in fact about 90 per cent. of the surface mixture with a small percentage of stone dust and mixed with the asphalt somewhat less than will fill the voids to prevent rolling. The surface must be hard enough to prevent caulking by horses, and soft enough to prevent cracking in winter which is between comparatively small limits in this climate. For about two years the asphalt surface becomes about 5 per cent. harder each year so that in repairing a penetration much less should be used for the new material.

In grading the sand we have followed the following standard as closely as possible usually by mixing sand from two or more different places:—

Passing	200	mesh	0%
"	100	"	12%
"	80	"	12%
"	50	"	26%
"	40	"	11%
"	30	"	16%
"	20	"	12%
"	10	"	8%
"	8	"	3%
			100%

200 mesh sand does not pack well, and is therefore, not so desirable as 200 mesh limestone dust, as it tends to make the pavement mush in hot weather.

The grading given above is somewhat coarser than usual, but it has been found that this mixture gives a richer mixture with the same amount of bitumen, and will also lessen the drying out of the pavement.

The mixture should reach the work at a temperature not less than 28 per cent., and spread with hot rakes for a depth of 3″ to give a compressed surface of 2″. This requires also some skill and care to obtain good results.

The asphalt pavements will cost, including binder, but not the base from 65 to 80 cents per square yard. It will stand up under heavy traffic better than any of the asphalt concrete mixtures (including the proprietary ones). It requires a certain amount of traffic to keep in condition, and for business streets it is better than the asphalt concrete mixtures that depend on the stone in them for their strength, which on account of the size is apt to move about losing the inherent stability of the pavement.

Asphalt block is composed generally of 77 per cent. crushed gneiss, 10 per cent. limestone dust, and 13 per cent. asphaltic cement put in moulds, subjected to a pressure of from two to three tons per square inch, after which it is slowly cooled in water, all of which is done at the factory. Their only advantage over sheet asphalt is that the blocks can be laid by unskilled labor, but there are few cases where sheet or concrete asphalt is not preferable, especially on account of its high cost of about 2.70 per square yard without the base.

Vitrified brick pavements have been used extensively in some of the larger cities in Ontario, but in the case of Hamilton it is no longer used for pavements, except alleyways, where it replaced concrete. A vitrified brick pavement is not so slippery as asphalt, is durable under moderate traffic, and requires no special plant for laying. The reason for the re-action against the brick pavements in some of the cities is that the people prefer wooden block as being much quieter and lacking the peculiar roaring noise produced by the passage of light wagons. Much credit has also been thrown upon the use of brick by the careless and ill-judged manner in which some manufacturers have sent out irregular or imperfectly burned brick, along with the laying by inexperienced city foremen; a brick that is too hard being just as bad as one too soft upon the bricks surrounding. One drawback is that a street paved with brick and grouted cannot be travelled upon for a week or two after being laid without injuring the joints, and this is almost impossible to prevent upon some streets with the consequence that the flushers afterwards take it out and leave the edges of the brick unprotected, which under traffic causes the edges to chip off. The pavement is laid on a concrete foundation usually with a two-inch cushion of sand to take up an unevenness of the brick and to spread the pressure on the base.

The brick pavement is well laid under good specifications will give as good satisfaction under moderate traffic as asphalt block, while the cost is much less, being about $1.55 without the base.

Stone block pavements are only desirable for steep grades on streets of large cities where the heaviest traffic exists. There is no such traffic in any city of moderate size, so that in Ontario there are very few places where it would be necessary. It is a difficult pavement to keep clean, is extremely noisy, and about the most expensive pavement that can be laid.

Treated wooden blocks have come into use in the past few years, and each year shows a large increase in the amount being laid. It is practically noiseless, free from dust, and will withstand the heaviest traffic. The writer examined pavements in New York wholesale district where the traffic was of the heaviest, and after eight years' use these pavements were in excellent condition. In Hamilton at the intersection of James and King Streets, where there is the heaviest traffic in the city, the wooden blocks show no indications of wear after four years.

Although some engineers call for less the consensus of opinion is that the blocks should be treated with twenty pounds of creosote oil per cubic foot, and even then there will be a certain amount of swelling of the pavement, as a small percentage of water can still be absorbed. There will be a little bleeding of the oil from the blocks during the first summer after being laid, but it generally disappears by the second season. Longleaf Georgia pine has been the wood usually specified, but good results have also been obtained from Norway pine, tamarac and birch when properly treated. The joints may be filled either with grout, or pitch, the latter being the better, increasing the cost of the pavement. The blocks are laid with the grain vertical, and laid in a one-inch bed of cement and sand upon a concrete foundation, blocks being driven together, but having expansion joints at each curb of 2″ and every 10′ across the pavement.

In Hamilton this pavement has become so popular that some residential streets have petitioned for it on account of its quietness, although it is a costly pavement running from $2.25 to $2.65 per square yard, according to the kind of block, whether plain or grooved for heavy grades. All of these pavements have assumed a concrete base 6″ thick at least on business streets, with a mixture not less than 1-3-6, which will cost from 50 cents to 60 cents per square yard.

Pavements of concrete and reinforced concrete are now being built, but it should be remembered that the hardest concrete is less durable and softer than the average brick pavement, hence the hardest obtainable surface should be constructed. Two-course and one-course pavements have been built, and successful pavements have been built under either specification on residential streets. It is now entering into competition with brick and asphalt on business streets, and its use under such conditions is doomed to failure, as streets where such pavements ought to be laid cannot be successfully paved with concrete. While there is a wide field for its use on highways, and many streets in cities, yet it is the duty of the engineer to recognize that concrete has its limitations like other paving materials. Its proper use, however, under proper specifications, will prove a profitable investment for property owners on many streets where low first cost is a consideration, as it can be laid at a cost of from $1 to $1.20 per square yard, including the base. Unfortunately commercial interests have sent forth a lot of literature booming this pavement under all conditions which will work to the injury of such pavements if carried out under such advice. The success of this pavement depends greatly upon the way it is laid and some of its failures may be traced directly to the poor workmanship even with good specifications. Other causes will be improper materials, lack of screening, improper mixing, careless placing of materials, faulty joints, neglect of protection and curing. These pavements are sometimes reinforced with wire mesh two inches beneath the surface to eliminate cracks and have successfully done so where otherwise under the existing conditions cracks would have appeared from settlement, freezing, or contraction.

Grades.—Much misleading information is given out as to the grades upon which pavements can be laid. It is misleading because the conditions are not named and while the grade may be satisfactory under conditions of light traffic, yet be far from it where heavy teaming exists. The writer has found that in the condition existing in Hamilton that macadam, or asphalt-macadam can be used safely to 8 per cent. bitulithic to 4 per cent. brick, 3½ per cent. asphalt to 3 per cent. wood 2½ per cent., or where grooved or spaced with both 4 per cent. for heavy teaming. For general traffic 1 per cent. may be added.

Street Railway Tracks.—While the street or suburban railways always want tee rails because of cheapness and deeper flanges, it is the policy of the city to insist upon girder rails. No pavement will last alongside the inside of the tee rail as long as the steel protecting lip of the girder rail and sooner or later there is a groove worn out alongside the inner face of the rail where loaded vehicles will pull off wheels and which will become dangerous to general traffic.

The rails should be at least 80 pounds per yard, preferably fastened to steel ties with clips spaced ten-foot centres, with one tie at each rail end. A poorer construction is with wooden ties fastened to the rails with spikes which are apt to work loose allowing the rail to move. Even with the heaviest construction there is a certain amount of vibration which has a tendency to loosen the blocks of the pavement adjacent to the rail, especially at the joints.

In conclusion I would say that where a small city or town is about to spend large sums on paving, that it is money well spent to retain a consulting paving engineer to work out the proper pavement for each street. Infinitely better results would be obtained than at present where the councils are pulled about by representatives of different paving interests, or where deputations from such councils are steered to other cities to look over carefully selected pavements by these same commercial interests.

THE MINER'S INCH.

On the Pacific coast, the unit for measuring water in mining is known as the miner's inch. This varies greatly in different localities, and is now generally defined by legislative enactment. The statute inch of Colorado, for example, is defined as "an inch square orifice, which shall be under a five-inch pressure measured from the top of the orifice to the surface of the water, in a box set in the banks of the ditch. This orifice shall in all cases be six inches perpendicular inside measurement, and all slides closing the same shall move horizontally, while from the water in the ditch the box shall have a descent greater than one-eighth of an inch to the foot."

In British Columbia, under the Water Clauses Consolidation Act, 1897, Section 143, a miner's inch is declared to be a flow of water equal to 1.68 cubic feet per minute. Therefore, a miner's inch is equal to .028 cubic feet per second, and 1 cubic foot per second is equal to 35.71 miner's inches, approximately. One cubic foot per second would be equal to 38.4 Colorado miner's inches.

THE RAILWAY SITUATION IN HAMILTON

PECULIAR LOCATION OF CITY CREATES PROBLEM—SOLUTION IS SPEEDILY NEEDED—CO-OPERATION OF LINES NECESSARY—FUTURE DEVELOPMENT WILL NECESSITATE CHANGES NOW CONTEMPLATED

By E. H. DARLING, M.E., A.M. Can. Soc. C.E.

SEVERAL very important questions are involved in Hamilton's railway problem, some of which are of recent origin, while others date back many years. First of all there is the growing need for better station accommodation for the existing steam roads. This is a chronic trouble in a rapidly growing city. There is the question of grade separation,—the elimination of grade crossings with their dangers and delays. There is the smoke and noise nuisance which gradually grows as the railway traffic increases. All this, but principally the fact that another steam railway is seeking right-of-way through the city, has impressed upon the minds of the city officials, and many citizens in general, that now is the time to consider the railway problem as a whole, and, if possible, to find some solution which will not only answer present needs, but will provide for the future growth of the city.

The location of Hamilton is such that it is extremely difficult to bring a railroad into it, quite apart from the thousand and one obstacles which are always encountered in locating a right-of-way through a thickly populated district. To the north lies Burlington Bay. On the south abruptly rises the Niagara escarpment or "mountain" to a height of over 320 feet above the centre of the city, and 400 feet above the bay. On the west lies the "marsh" and the broken irregular Dundas valley. Between the marsh and the bay is a narrow ridge of land or "Hog's Back," a hundred feet in height, extending diagonally across the city. On the east, the level flats of the Niagara fruit district, permit an easy access, but this only for a line from Niagara Falls.

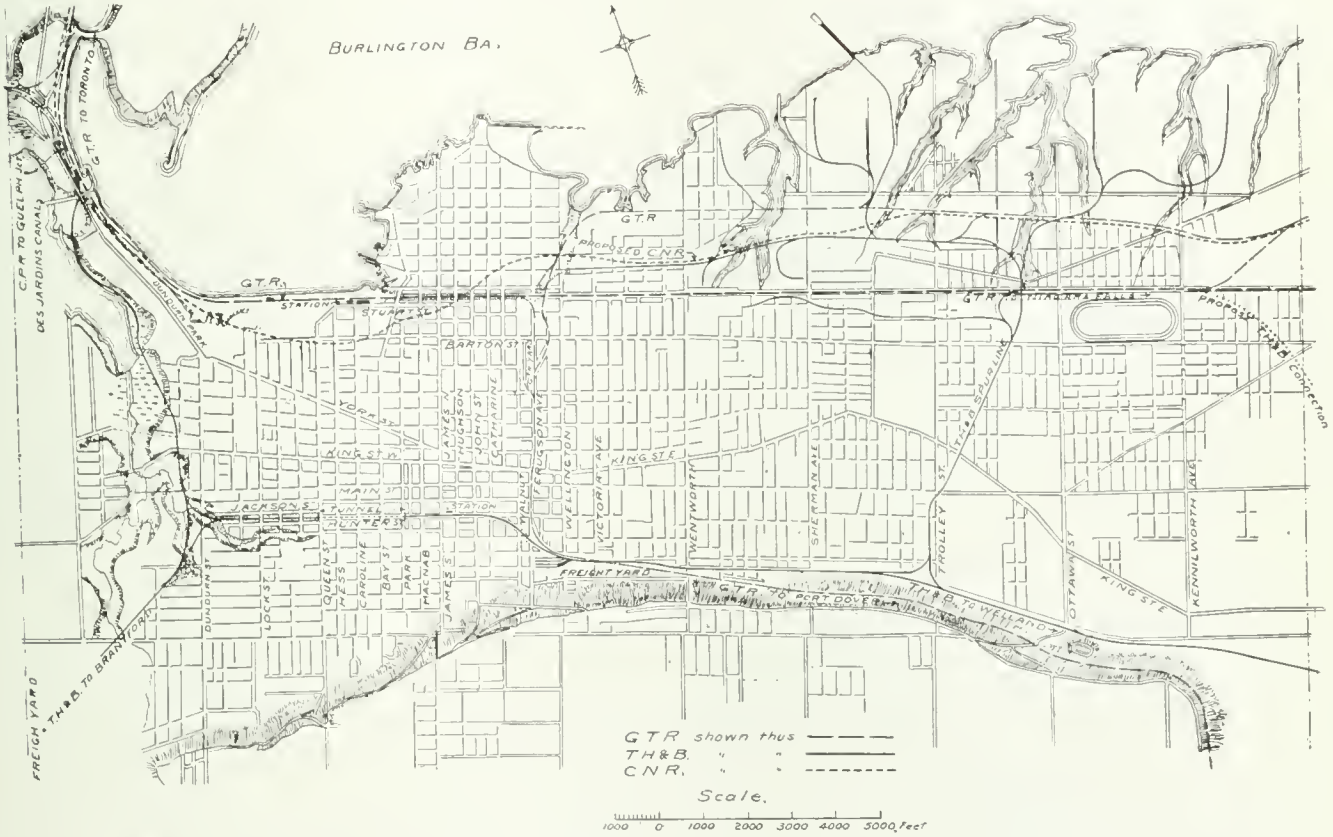

Fig 1.—Diagram of the city of Hamilton Showing existing railroads and proposed route of the Canadian Northern Railway.

Over fifty years ago the Great Western Railway, (now the Grand Trunk), occupied the bay shore. Its Port Dover branch (the old Northwestern Railway) cuts across the city and climbs the mountain to the eastward. In 1894-5 the Toronto, Hamilton and Buffalo Railway tunnelled the "Hog's Back" and entered between the centre of the city and the mountain. Last year the Canadian Pacific Railway, Guelph Junction branch, connected with the Toronto, Hamilton and Buffalo outside the city at the Des. Jardine Canal, (See Fig. 1). Besides these steam roads there are five suburban electric roads each with its independent entrance. These, with the street railway system, occupy most of the main streets.

About two years ago the Canadian Northern Railway began buying land for a right-of-way through the city, and filed their plans with the Railway Commission. Their plan is to follow the Grand Trunk Railway around the end of the bay, keeping at a higher level, cutting through Dundurn Park and striking the grade of the city streets about Bay Street. (See Fig. 1). From here there are three alternative routes to Ferguson Avenue. (Only the southerly one is shown). The remainder of the right-of-way follows the spur line of the Toronto, Hamilton and Buffalo and the Grand Trunk Railway, Burlington Beach Branch, to the city limits.

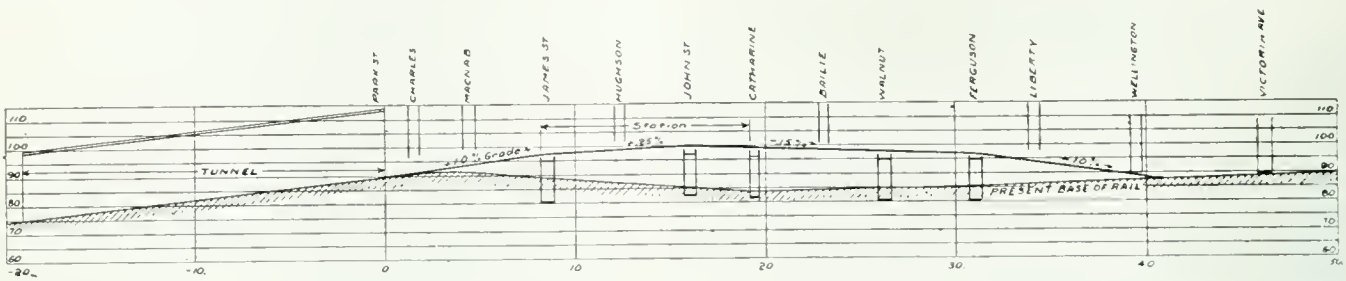

Fig. 2.—Profile of track elevation plan for the Toronto, Hamilton and Buffalo Railway, by Westinghouse, Church, Kerr and Company.

This route has called forth strenuous opposition from many quarters, principally on account of the many grade crossings and the injury to Dundurn Park and other property. The fact that the proposed line follows the Grand Trunk Railway so closely, naturally suggested the idea of a common right-of-way and a union station. In this case the Canadian Northern Railway would come along the north shore of the bay, bridging the end at the long peninsula, (shown on Fig. 1), keeping outside of the Grand Trunk Railway and following the same grade.

While this question was before the public an agitation had been developing, in the south end of the city, against the Toronto, Hamilton and Buffalo Ry. The conditions under which this road operates to-day are far different to what they were when it was built in 1894-5. Since that time the city has doubled in population and the number of residents south of the tracks has increased more than this in proportion, not counting the rapidly growing section on the mountain. The Railway Company has grown even more rapidly than the city. Its connections with the Vanderbilt lines through the Michigan Central and the Canadian Pacific Railway to Guelph and Toronto, make it the entrance of these two great systems.

The number of trains per day has greatly increased. Also, they have become heavier, longer, and operate day and night. As the station platform is only a short city block in length,—(about three hundred feet)—it is impossible to handle this heavy traffic without more or less blocking of streets. This, with the noise and smoke, is what the residents in the neighborhood are complaining about.

For some time it is believed that the Toronto, Hamilton & Buffalo Ry. has been buying lands on either side of its right-of-way for the purpose of adding tracks and increasing the station accommodation. There is also a probability that the Canadian Pacific Railway will build a line to Niagara Falls, using the Toronto, Hamilton and Buffalo Ry. right-of-way through the city and station. The fear of some such step has done more to arouse those interested to action than the other things they complain of. Their hope is to forestall the Railway Company, so that when the time comes to extend their station they (the company) will be committed to a plan that will not only be unobjectionable but will relieve present troubles.

At the last municipal election the residents on Hunter Street, and in the neighborhood, organized to work for

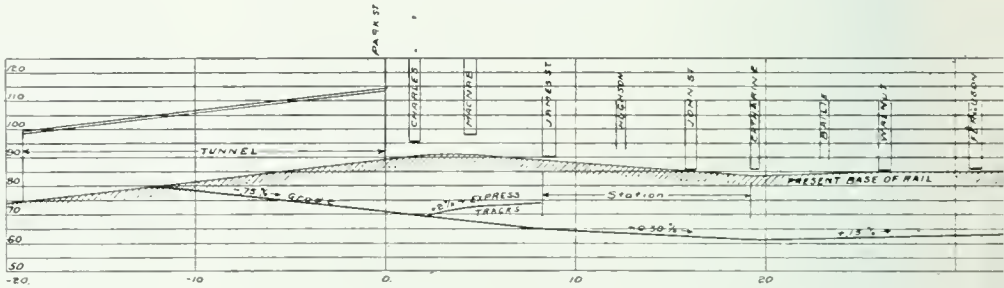

Fig. 3.—Profile of track depression pl

candidates who would agree to support their efforts in the city council. Since then the matter has been brought to a head by the sending of a largely-signed petition to the Railway Commission, asking that the Toronto, Hamilton and Buffalo Ry. be ordered to remove its tracks from Hunter Street.

It was while this matter was pending that the city authorities, acting on the suggestion of the City Engineer, approached the officials of the Grand Trunk Railway, the Canadian Northern Railway, and Toronto, Hamilton and Buffalo Ry. to ascertain if they would consider a plan of uniting to use a common right-of-way through the city, and of building a union station.

There are many reasons why this scheme is desirable from the city's point of view. In the first place, Hamilton is so confined between the mountain and the bay that an independent right-of-way through it effects as much as 10 per cent. of the city. The granting of another right-of-way is therefore a serious proposition.

(2) It would be a decided convenience to have all the steam roads use a union station just as do the electric lines, and thus do away with awkward transferring from station to station. If the union station were placed somewhere near the corner of James and Barton Streets it would be more convenient for a large majority of the citizens than at any other point for it would be within easy walking distance from the centre of the city and every street car line, with one exception, passes through that point without transfer.

(3) The land along and adjacent to Hunter Street, on account of the rapid growth of the city is becoming

very valuable (or would be if the railway were not there) and will be needed for the future growth of the business section. The land in the north end, as pointed out by the City Engineer, has reached its limit in value for residential purposes, and is more suitable for manufacturers and railroads.

(4) The proposed improvement to Hamilton harbor by the Dominion Government will make it all the more desirable to concentrate the transportation companies in the north end.

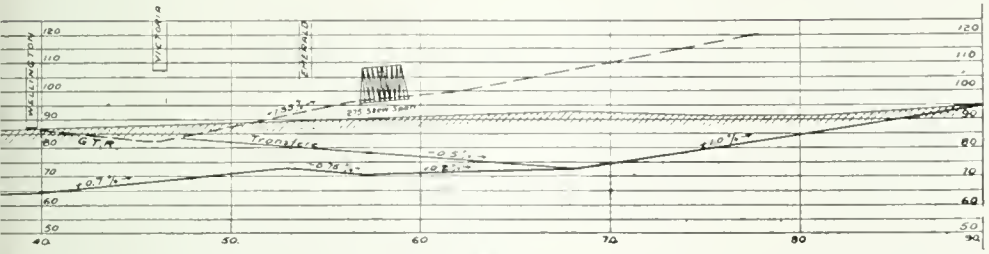
(5) The street traffic in the centre of the city has already become so congested that it requires special regulation, and as the city grows it will become more and more important to clear the streets now more or less obstructed by the Toronto, Hamilton and Buffalo Ry.

(6) At present the Toronto, Hamilton and Buffalo Ry. has a spur line across the city into the manufacturing district. A glance at (Fig. 1) shows a regular network of switches, and only the main ones are indicated. From these are collected every day several train-loads of freight, which are now transferred across the city, up heavy grades, the most of it travelling along Hunter Street to the west end freight yards. If all this traffic, along with the through freight, could be diverted to the Grand Trunk Railway right-of-way and taken to the yards by way of the Des Jardines Canal, practically every objection of the Hunter Street residents would be done away with. Besides it would not only bring the Railway Company within reach of new customers, but it would apparently be a convenience in handling freight.

Taking everything into consideration the common right-of-way scheme would seem to be a very satisfactory solution to the railway problem from the city's point of view, and the officials were correspondingly disappointed when, after the Grand Trunk Railway and Canadian Northern Railway had signified their willingness to confer on the question, the Toronto, Hamilton and Buffalo Ry. recently absolutely refused to consider it. However, the city decided to go ahead with the preparation of plans and of an estimate of the cost of connecting the Toronto, Hamilton and Buffalo with the Grand Trunk Railway, and will also ascertain if the Railway Commission has power to order the railway to make the change. The plans are now ready but have not yet been made public.

The attitude of the Toronto, Hamilton & Buffalo Ry. on this question is hardly to be wondered at. The company has very little to gain directly, even if it has nothing to lose. Its franchise through the city is of great value, quite apart from the actual value of the property it holds. This value increases every year as the city grows. The present location of its station affords an advantage in passenger traffic that is estimated at four to one. This, however, would be very materially effected should the Grand Trunk Railway build a proper station near James and Stuart Streets. There is one thing, however, that might make it worth while for the Toronto, Hamilton and Buffalo Ry. to consider the union station scheme and that is the outcome of the petition to the Railway Commission mentioned above, which might be an order to depress or elevate its tracks through the city.

Coming back to this petition. In replying to it the Toronto, Hamilton & Buffalo Ry. submitted a report, prepared by Westinghouse, Church, Kerr and Company, of New York, in which plans for both elevating and depressing the tracks through the city were worked out, with an estimate of the cost. These plans are both on the basis that the present alignment is to be



Westinghouse, Church, Kerr and Company.

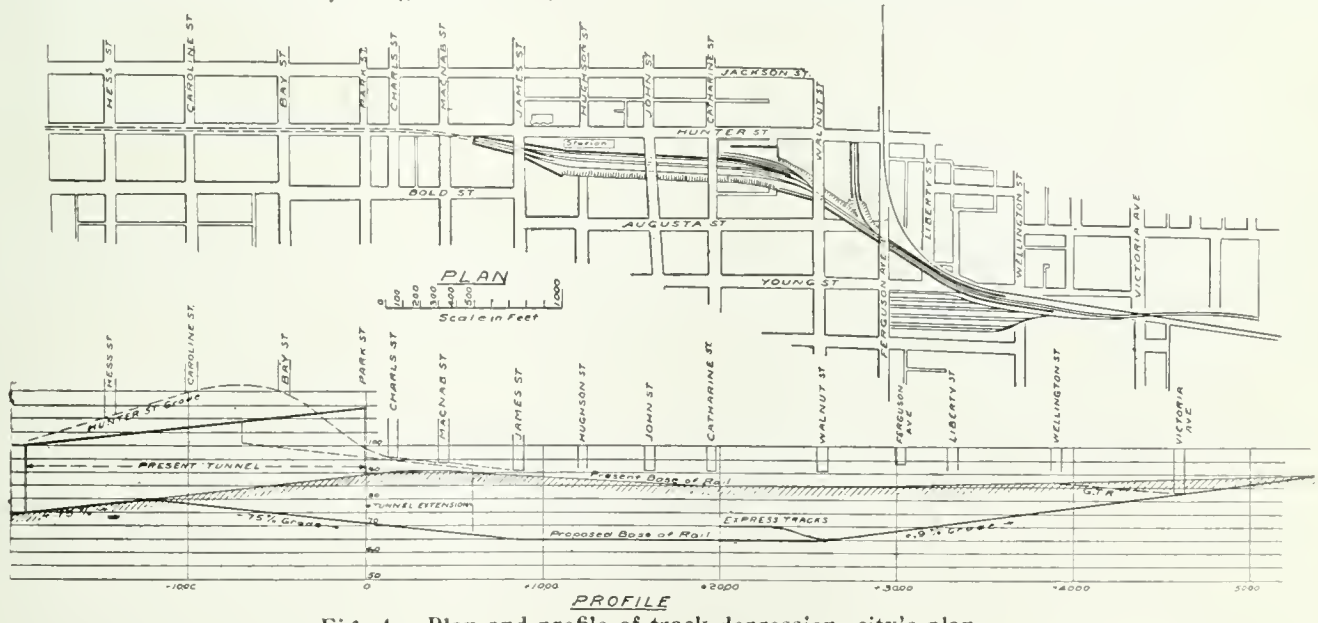


Fig. 4.—Plan and profile of track depression, city's plan.

maintained. At the session of the Railway Commission held in Hamilton, on April 28th, 1913, at which the case came up, the city submitted a third plan showing the tracks depressed and swung entirely off Hunter Street,

or covered in a tunnel.

A rough estimate of the cost of the three plans is as follows:—

Plan No. 1.—For elevating the tracks.....	$760,000
Plan No. 2.—For depressing tracks	2,940,000
Plan No. 3.—For depressing tracks, city's plan	1,200,000

These figures do not include land damages. For plan 3 in which this item is larger than for the other plans, it is estimated that these would amount to $310,000, allowing for salvage on property owned by the Toronto, Hamilton and Buffalo Ry.

All these plans include extensive additions to the station platforms, tracks, etc., which are much needed at present, and the cost of which should not be included in the actual cost of grade separation.

Fig. 2 shows the profile of the track elevation plan as worked out by Westinghouse, Church, Kerr and Company. Beginning at the mouth of the present tunnel the track rises on a 1 per cent. grade to James Street, where the station platform begins. James Street is depressed about nine feet and John, Catharine, Walnut and Ferguson Avenues, are depressed from three to six feet. The maximum street grade is 5 per cent. The following streets are closed entirely; Charles Macnab, Hughson, Bailie and Liberty Streets, while Hunter Street would be diverted and only one side-walk left on the present street. This plan is probably the least expensive and most satisfactory way of eliminating grade crossings from a construction and operating point of view, but to the city it would mean the loss of Hunter Street, the closing of five other streets and the introduction of long heavy grades in some of the main business streets. A glance at Fig. 1 will show that every north and south street from James to Bay Streets,—a distance of a quarter of a mile, would be practically closed as the grade on Park Street, over the portal of the present tunnel, makes it useless except for very light traffic. The embankment through the city would do more to depreciate property than the present tracks, while the trouble from noise and smoke would be increased rather than diminished, on account of the heavy grades.

A profile of the alternative plan is shown in Fig. 3. This is a comprehensive plan from depressing the tracks not only under the main streets of the city but also under the Grand Trunk Railway tracks of the Port Dover Branch. The change in grade begins about 1,200 feet west of the east portal of the present tunnel, and would necessitate the rebuilding of part of the tunnel. Other expensive items would be the 275-foot skew-bridge for the Grand Trunk Railway and the bridge at Victoria Avenue. The presence of the transfer tracks east of this point makes a double cut necessary.

Plan number three of which a profile is shown in Fig. 4 was developed by the Hunter Street residents and adopted by the city. It is a much simpler proposition. It would require the rebuilding of 700 feet of the present tunnel and the extension of it eastward for a distance of 600 feet. But the main feature is the complete deviation of the line off Hunter Street. This would restore Hunter, Park, Charles and Macnab Streets to their original grade and free them from obstruction. On the east the present grade is reached at Victoria Avenue. East of this street the railroad is practically out of the city as there is no land of much value between it and the mountain.

There will probably be a joint meeting of the engineers of the parties interested early this fall to go over the plans and reduce the estimates to a common basis. The Railway Commission will then be in a position to consider the question.

REINFORCED CEMENT DRAIN TILE.

MR. CHARLES E. SIMS, writing in "The Iowa Engineer," refers to a contract which he secured in the spring of 1912, for the 30 to 42-inch cement drain tile for Rock County, Minn. The contract called for 3,700 feet of 42-inch tile, 1,500 feet of 34-inch, 1,300 feet of 32-inch and 2,200 feet of 30-inch. The 42's were to be laid at an average depth of 17 feet 9 inches and a maximum of 22 feet and 6 inches; the 34's at a maximum depth of 13 feet 6 inches, the 32's at a maximum of 11 feet 4 inches and the 30's at 9 feet 7 inches.

The earth pressure at the greatest depth of the 42's, figuring the trench 62 inches wide, was estimated at 5 tons per foot, or 15 tons on a tile 3 feet long. The engineer, in charge, specified a wall thickness of 4 inches and a system of reinforcing consisting of 6 wire hoops placed in pairs 8 inches apart in the length of the tile, and the hoops of two sizes, such that one set was to be 1 inch smaller than the outside diameter of the tile.

It might have been a saving of metal to have used a deformed steel bar in place of a pair of hoops, since the earth pressures may be assumed to be vertical, and theoretically, therefore, the need for reinforcement exists only at the inside of the tile wall at top and bottom of the tile and at the outside of the tile wall at the sides. To make this clear let us imagine a tile failing from the load upon it. As the tile fails, cracks open on the inside at top and bottom and on the outside at the sides, hence reinforcing is needed where the cracks can first be seen. It was a question, however, whether the earth pressures would always be vertical; for the banks of a trench of such depth may be expected to cave, in which event the single bar reinforcement might not come at the right place to be effective and the tile be no stronger than it would have been without reinforcement. The wire hoops were, therefore, considered the better type of reinforcement.

To avoid all risks the reinforcing was placed in the tile 6 inches centre to centre instead of 8 inches, and all tile for the deepest positions were made of alternately No. 6 and No. 3 wire hoops. Further, the wall thickness was increased from 4 inch as specified to 4½ inch and the wires purchased of such diameter as to cover them ¾ inch from the surface of the concrete.

To make sure that the hoops when dropped into the tile mold would come to the desired position in the concrete, the hoops were wired together in four or five places with No. 16 wire ties, each end wound around the hoop wires and made to project outward ⅝ to ¾ inch. This process is not expensive, one man being able to tie 250 pairs of hoops in ten hours.

The tile were made in 3 foot lengths. One part Portland cement to 3 parts of sand and gravel was used for the concrete, and as much water as possible, with the result that the tile made have watertight walls, and it is believed that the bond between the reinforcing and the concrete is all that is necessary for strength and preservation of the metal.

The smaller sizes of tile were made of wall thickness equal to one-tenth the inside diameter of the tile and reinforced 8 inch centre to centre with No. 7 wire hoop placed 5/8 inch from the surface of the concrete, except the 30 inch, which were made with the walls one-twelfth the diameter of the tile, as they would not be used for six months after manufacture and the thinner wall was deemed sufficient, with good materials, mixed wet and tamped densely.

The 42's have been shipped 45 miles without breakage, and hauled seven miles frequently when but ten days old, thus demonstrating the quality of material and the effectiveness of the reinforcing in reducing breakage. A thousand feet of the tile are now in place, some under a fill of two-thirds the maximum due to tamping the fill at the sides of the tile.

PROGRAMME OF THE AMERICAN ROAD CONGRESS.

The American Road Congress, which is held under the auspices of the American Highway Association, the American Automobile Association, and the Michigan State Good Roads Association, and in which some twenty-five Road Associations will participate, is being held in Detroit, September 29th to October 4th.

The following is a list of papers to be presented. They will be read by title only, advance proofs being previously circulated and the sessions of the Congress given over to prepared discussion.

"The Labor Problem in Road Construction," by Captain P. St. J. Wilson, State Highway Commissioner of Virginia. Discussion to be opened by Mr. W. E. Atkinson, State Highway Engineer of Louisiana.

"Systematizing the Purchase of Road Materials and Equipment," by Mr. Henry G. Shirley, Chief Engineer, State Roads Commission of Maryland. Discussion to be opened by ——.

"Unsurfaced Roads," by Mr. W. S. Keller, State Highway Engineer of Alabama. Discussion to be opened by Mr. George W. Cooley, State Highway Engineer of Minnesota.

"Gravel Roads: Their Construction, Maintenance, Cost and Special Treatment," by Hon. S. Percy Hooker, State Superintendent of Highways of New Hampshire. Discussion to be opened by Mr. H. L. Bowlby, State Highway Engineer of Oregon.

"Treatment of Worn-out and Ravelled Macadam Surfaces," by Colonel E. A. Stevens, State Highway Commissioner of New Jersey. Discussion to be opened by Hon. Robert C. Terrell, State Commission of Public Roads of Kentucky.

"Bituminous Macadam Construction and Maintenance," by Mr. S. D. Foster, Chief Engineer, State Highway Department of Pennsylvania. Discussion to be opened by Mr. W. A. McLean, Provincial Engineer of Ontario, Canada.

"Brick Roads," by Mr. James M. McCleary, County Engineer of Cuyahoga County, Cleveland, Ohio. Discussion to be opened by Mr. R. Keith Compton, chairman Paving Commission, Baltimore, Md.

"Concrete Roads," by Hon. Frank F. Rogers, State Highway Commissioner of Michigan. Discussion to be opened by Mr. Paul D. Sargent, State Highway Engineer of Maine.

"Selection of Road Materials," by Hon. Logan Waller Page, Director, United States Office of Public Roads. Discussion to be opened by ——.

"Dust Prevention," by ——

"Drainage Structures," by Mr. A. R. Hirst, State Highway Engineer of Wisconsin. Discussion to be opened by Professor T. H. MacDonald, State Highway Engineer of Iowa.

"California's $18,000,000 State Highway System," by Mr. A. B. Fletcher, State Highway Engineer of California.

"Highway Accounting, with Special Reference to Maintenance," by Mr. Halbert P. Gillette, Editor-in-Chief, Engineering and Contracting.

"The Organization and Management of Working Forces," by Mr. A. N. Johnson, State Highway Engineer of Illinois.

"Contract Law," by Mr. William Bowman, of New York.

"The Protection and Upkeep of Road Equipment," by Mr. Daniel J. Hauer, of New York.

"The Merit System in Road Management," by Hon. J. A. McIlhenny, President United States Civil Service Commission.

"Financing Road Improvements," by Mr. Wm. G. Edens, President Illinois Highway Improvement Association.

"Bond Issues for Road Improvement," by Mr. S. E. Bradt, Vice-President First National Bank, DeKalb, Ill.

"The International Congress and the Roads of England, France and Germany," by Col. Wm. D. Sohier, chairman, Massachusetts State Highway Commission.

"Economics of Road Improvement," by Mr. J. E. Pennybacker, Secretary, American Highway Association.

"Dirt Roads and Politics," by Mr. Charles P. Light, former State Highway Commissioner of West Virginia.

Addresses by Hon. James H. MacDonald, Dr. Jos. Hyde Pratt, Mr. Clarence A. Kenyon and others.

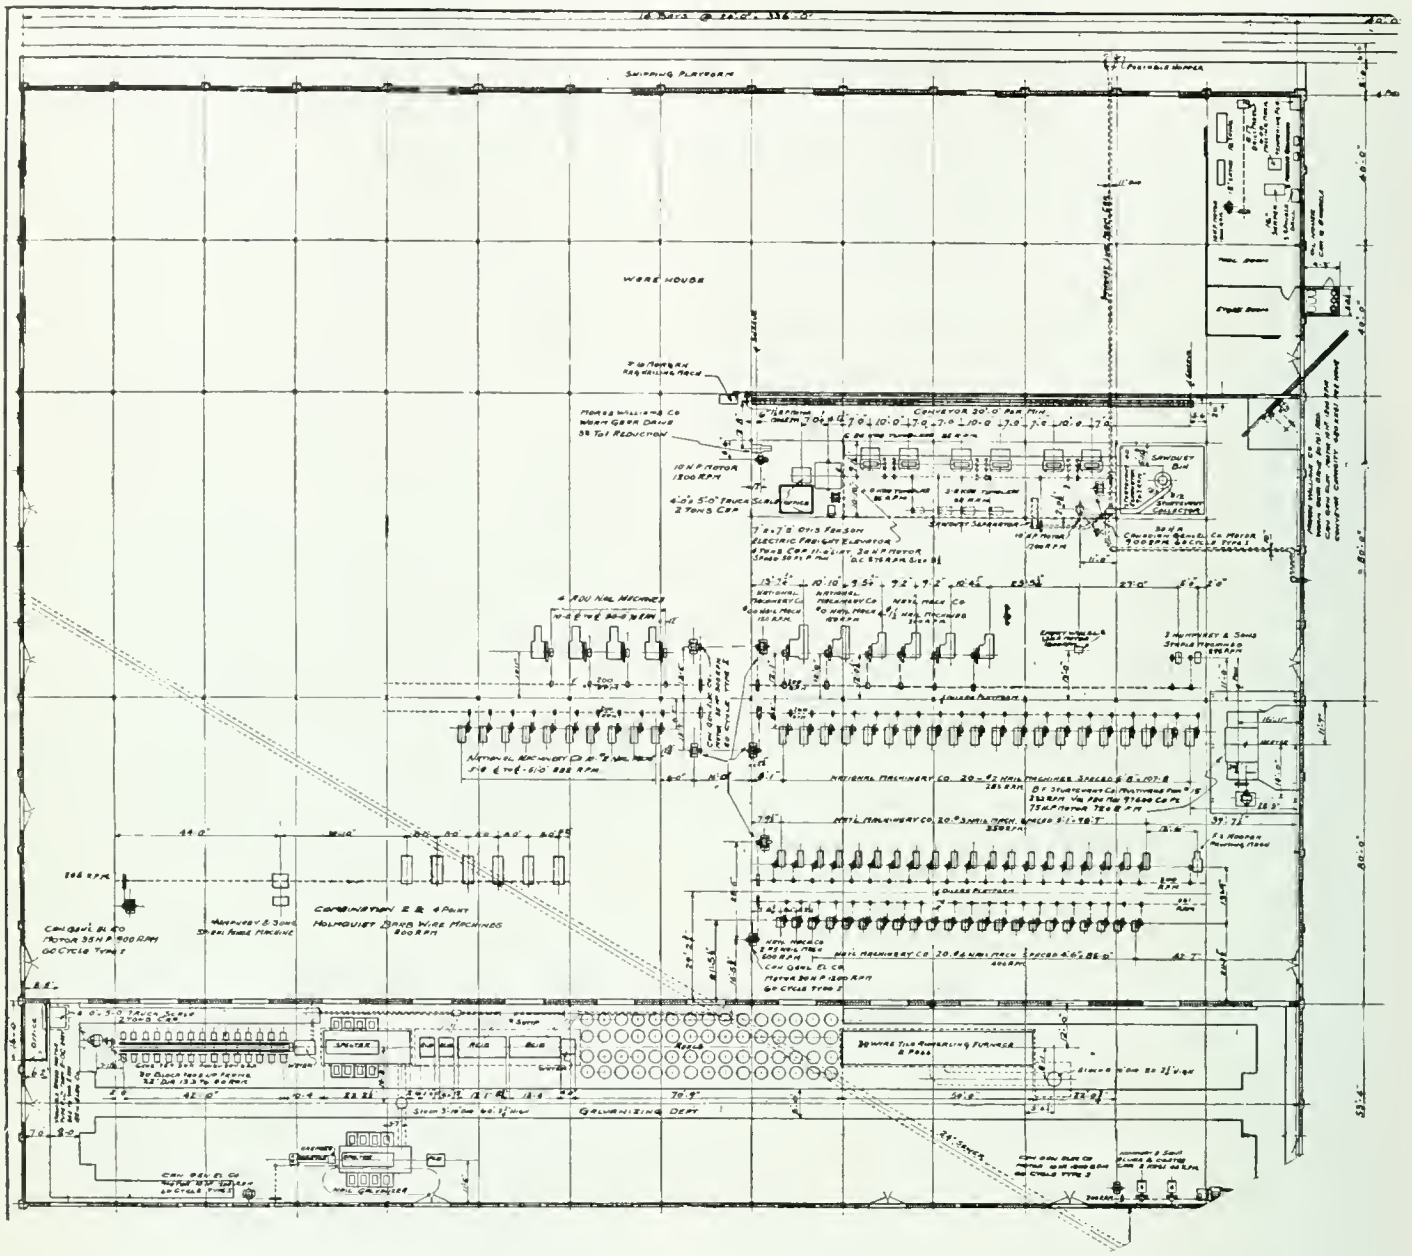
THE STRENGTH OF WALL AND COLUMN FOOTINGS.

In a bulletin recently issued by the University of Illinois, Professor A. N. Talbot gives the results of 114 tests made on the strength of wall footings, and of 83 tests on the strength of column footings. The wall specimens were in the shape of ⊥, the table being generally 5 ft. long by 12 in. deep, and the stem, representing the wall, was 12 in. square. During the tests the specimen rested on a nest of helical car-springs, of which as many as 225 were used in some tests. The load was applied to the top of the stem, and failure occurred generally by bending about a section parallel to one face of the "wall." The tests included footings of brick and of plain concrete, as well as of reinforced concrete, but the latter only gave fairly consistent results. The unreinforced specimens showed great irregularities. With the reinforced footings, on the other hand, the results were in fair accord with the ordinary theory of the reinforced concrete beam. The reinforced column footings were 5 ft. square and 12 in. deep, and the column was represented by a stem 12 in. square. As in the experiments with the wall footings, the specimen was supported during the test on car-springs. The general question of the distribution of stresses in slabs is discussed by Professor Talbot on a qualitative rather than a quantitative basis, the problem being, of course, of a very complicated character. This fact makes it difficult to give any really useful summary of the results, of which, however, full particulars, with illustrations of characteristic cases of failure, will be found in the bulletin.

THE WIRE AND NAIL MILLS OF THE DOMINION IRON AND STEEL COMPANY, LIMITED.

Like almost all the large and successful enterprises, the works of the Steel Company at Sydney, N.S., have grown by a process of evolution. In the earliest days the output was confined to pig iron and steel in its primary forms, the manufacture of which is not always profitable, but without which there can be no permanent or satisfactory development of the secondary industries producing more highly finished materials. Later, when the expanding trade of the country seemed to warrant a forward movement, mills were erected to produce rails, billets and wire rods. During the past year a third stage of development was reached by the completion of the Merchant Mill, described in *The Canadian Engineer* of July 31st, and the establishment of a department for the manufacture of a large scale of all kinds of wire and wire products, including not only various sorts of wire nails required for the home market, but others specially adapted for export.

An indication of the importance of this latest development of the works is given by the fact that the buildings in which the various processes are carried on for the conversion of rods into wire and nails cover no less than four acres of ground and that the tracks serving these buildings and connecting them with the company's general railroad system take up nearly as much more.



General Arrangement of Nail and Wire Mill, Dominion Iron and Steel Company, Sydney, Cape Breton.

Briefly stated, the course of operations is as follows: Rods, coming direct by hook conveyer from the rod mill, are prepared for drawing by cleaning and coating, they are then drawn into wire which may be finished for sale plain as it comes from the drawing blocks, or as annealed or galvanized wire. Part of the galvanized wire is put through machines which convert it into fencing of one sort or another. A large part of the plain wire is sent to the nail mill where it is made into nails of all patterns and sizes from a quarter of an inch to twelve inches in length, bright, coated, blued or galvanized.

For convenience, the departments in which these various processes are carried on may be described separately.

Cleaning and Coating Department.—The cleaning house occupies a space 94 ft. by 160 ft. with a lean-to on the west side for storage of acid and lime. It contains acid and water rinsing tubs, lime coating tank, measuring tank, two jib cranes and a baker with ten tracks and capacity for ninety trucks.

Rods in bundles are delivered to cleaning house by hook conveyer direct from the mill. They are first placed in the acid tubs to remove scale and rinsed in the water tub. They are then thoroughly coated in the lime tank and heated in the baker until the lime coating is firmly set and the rods are ready for drawing.

Wire Drawing Department.—This immediately adjoins the cleaning house, covers a space of 94 ft. by 192 ft., and contains seven wire-drawing benches equipped with 83 twenty-six-inch blocks of the most modern types. The benches are separately driven by six 100 h.p. and one 150 h.p. motors, through Morse silent chain drivers. Provision is made for making and annealing and tempering the steel plates through which the wire is drawn.

Annealing is done either in a muffle furnace set near the baker in the cleaning house, or in four coal-fired annealing pots housed in a building 33 ft. by 80 ft., served by a five-ton overhead electric crane.

Nail Department.—This occupies a space 240 ft. by 336 ft., and is equipped with eighty-two nail machines designed to make a great variety of sizes and patterns of nails, including some that have not been previously made in Canada. There is a full equipment of tumblers and other accessories, including a package printing press and automatic nailing machines, and a tool-room fitted up for making the dies required for the nail machines.

A space 80 ft. wide and running the whole length of the building is reserved for storage and has capacity for 80,000 kegs.

Galvanizing Department.—This is under the same roof as the nail mill on the west side, but is separated from it by a brick wall. The whole floor space, 53 ft. by 330 ft., is occupied by apparatus required for galvanizing wire and wire nails.

In the wire galvanizing process the wire is given two passes through a tile annealing furnace and afterwards goes in succession through water and acid baths, a pan of molten spelter and a water tank. It is then wound on electrically driven take-up blocks or reels, of which there are thirty in all, forming coils 22 inches in diameter inside.

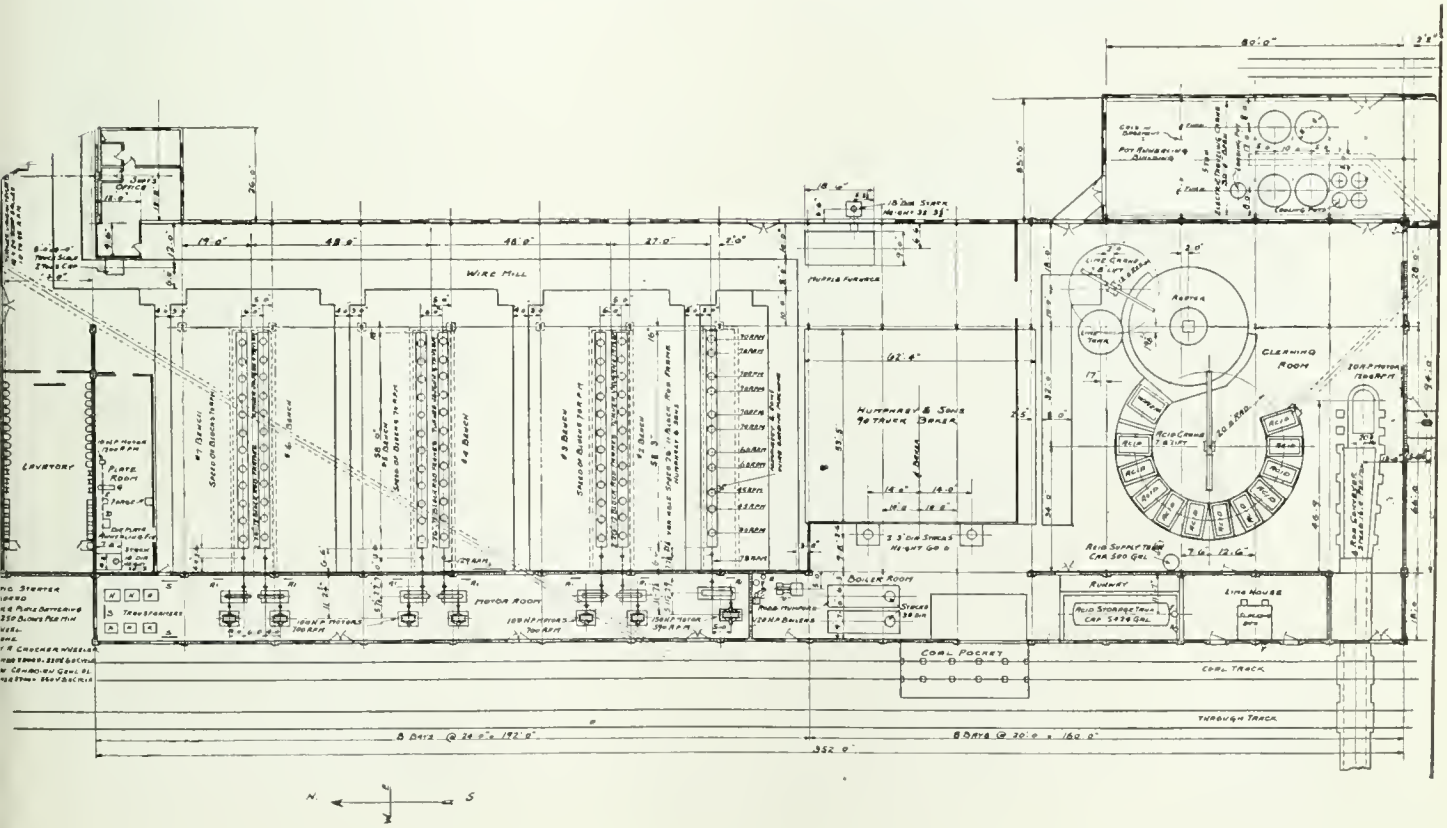
Coming from these reels the wire is ready to be bundled for shipment or to be put through the fence machines, of which there are six in the main building. This branch of the business might be largely increased, but at the present time conditions are such that there is little inducement for expansion.

The nail galvanizing unit consists practically of a tank for holding melted spelter into which the nails, previously cleaned, are dipped in steel baskets and a shaker and conveyer upon which they are kept in motion until the coating of spelter has cooled and set and there is no longer any danger that they will stick together.

Cooperage.—The cooper shops are housed in a two-story brick building, 40 ft. by 80 ft., with a single-story frame and corrugated iron extension the same size for storage of shooks.

They are fitted with dry kilns and suitable machinery for turning out an adequate supply of steel-bound nail kegs. The staves and heading are provided by the Sydney Lumber Company, Limited, one of the subsidiaries of the Steel Corporation, having its base of operations in the Restigouche county in New Brunswick.

Construction and Equipment.—Except where otherwise stated, the whole of the buildings are of steel and concrete construction with roofs of the high and low bay type, giving ample supply and even distribution of light.



Motive power throughout is electric. Steam for dry kilns, cleaning house and heating is furnished by 500 h.p., W.T. boilers. The buildings throughout are served by a Sturtevant heating and ventilating system. Lavatories and toilet rooms equipped with all modern conveniences are provided for the use of the employees.

Self-Dependence.—In this latest development of its varied activities there is a striking illustration of the ability of the Steel Corporation to carry on its business independently of aid or opposition. It wins the ore, coal and flux from its own mines and quarries, smelts the ore in its own furnaces, carries the resulting pig iron in its own works through the various processes that are necessary to convert it into the finished article that is required by the consumer, puts it in a package made in its own shops from lumber cut in its own mill from timber taken from its own lands, and delivers it to the user in the heart of the Dominion by means of its own ships.

What this really means is, that practically every cent of the value of a cargo of rails, or nails, or wire laid down at Port Arthur or Winnipeg, manufactured and transported under conditions such as are described above has been paid to our own people—and that not one cent has gone abroad.

The same statement could not be made if the pig iron were imported and made into steel, if steel billets were imported and made into rails or rods, or if rods were imported and made into wire and nails. The fewer the operations done at home the smaller the earnings of the home people; and the more complete the chain from the earth to the article ready for use, the more independent the nation and the greater its earnings and wealth.

The ground plan shown herewith needs no particular explanation beyond what has already been given.

ELECTRIC RESISTANCE OF MAGNETIZED GRAPHITE.

Magnetization affects the electric resistance of elements in different ways, generally increasing it, but decreasing it in the case of ferro-magnetic metals. This influence is several hundred times stronger in cadmium than in tantalum and bismuth. When investigating the magnetic properties of the elements, Morris Owen, Amsterdam, found that graphite possessed exceptionally high magnetic susceptibility. It, therefore, occurred to D. E. Roberts that the electric resistance of graphite would also be very greatly altered by magnetization, and his experiments entirely confirm this assumption. They also showed, however, that different specimens of graphite behave very differently, just as Owen had found that the magnetic properties of the elements were very much affected by their purity. Roberts experimented first with ordinary lead pencils, and afterwards with prismatic bars of various graphites, the specimens being about 10 mm. long, 1 mm. or 2 mm. in width, up to 0.5 mm. in thickness, at temperatures ranging from —200 deg. Cent. to + 200 deg. Cent. Some of his graphites conducted nearly half as well as mercury under ordinary conditions. When the graphite was magnetized, the direction of the lines of force being at right angles to the plane of cleavage, the electric resistance for continuous currents increased by several hundred per cent. in many cases, but the values fluctuated very much. As the temperature rose, the increase in resistance was generally less marked, but on the other hand it was sometimes also more clearly defined.

COAST TO COAST.

Vancouver, B.C.—The city has under consideration the expansion of the water system by the purchase of the watershed of Seymour Creek and the construction of a large reservoir or storage basin therein, a project which will involve much engineering.

St. Boniface, Man.—About two weeks ago the formal opening took place of the new stock yards at St. Boniface, Man. The function brought together a representative gathering of public men, and after Premier Roblin had declared the yards open, the party inspected the yards, which possess considerable interest for the engineer and the contractor. The contract for the laying of the sewers, water mains, together with all the concrete work, constitutes a problem that is quite interesting in itself when it is remembered that the pavements alone cover an area of 65,000 square yards. The paving consists of a concrete base 5½ inches thick, the mixture being 1:3:5. On top of this there is a one-inch thickness of finish, one part cement to 1½ parts coarse sand. The base and topping took 12,000 cubic yards of mixture. The runways for the cattle from the landing platforms to the level of the pens are all built of concrete. Altogether, it is an interesting piece of concrete construction. The contract for laying the sewers, water mains, laterals and concrete paving was carried out by the Hurst Engineering and Construction Company, of Winnipeg.

Brantford, Ont.—Ratepayers living on Brant Avenue became incensed over the deplorable condition of the street pavement, and have stated their intentions to the city council of refusal to pay charges upon the work when the tax bills are due in October. They state that they are prepared to go to the courts if necessary in defiance of any attempt on the part of the city to exact payment. Meanwhile, the paving company has received several ultimatums to repair the street, but nothing has been done, although the nuisance has prevailed for several months. Latest report has it that the city council has instructed that proceedings be commenced against the Westrumite Company to enforce the company's contract with the city for keeping the Brant Avenue in good repair.

Toronto, Ont.—The new Ontario Highway Commission has constructed a programme for the balance of the year that involves the collection of an immense quantity of statistics covering provincial road conditions, expenditure, and traffic, for each municipality. This will include data gathered from the United States, and concerning the experimental road work which many of them are doing. From the course adopted it is evident that the new system will primarily serve the interests of the farmer, and will endeavor to achieve a proper proportioning in the interests of the agriculturist and the automobilist. Laws and regulations, economic features, finance, construction and maintenance, and educational facilities is a summary of the work which the commission has undertaken for the next few months.

Calgary, Alta.—Analyses of the sample of Calgary drinking water sent to Edmonton recently by Dr. Stanley Mahood, medical health officer, show that the water from the Bow River, now being pumped into the city mains, is free from colon bacilli, which is a practical indication that there are no typhoid germs present. Dr. Mahood expressed himself as pleased with the result of the analyses, but pointed out that the city will soon be in a position to protect itself absolutely against possible contamination through daily analyses of the drinking water. "The new municipal laboratory, with City Chemist Field in charge, will be ready to make analyses of our water, beginning next week," said Dr. Mahood, "and the tests of the water will be made daily. This will enable

us to keep a constant check on our water supply, and will be of the greatest assistance to the health department." At the present time the water that is being pumped into the mains from the Bow River is chlorinated to destroy harmful germicidal life. The chlorine, however, to a certain extent favors the propagation of harmless bacilli, as shown by the Edmonton test. The water taken direct from the Bow showed 7,400 bacilli to the cubic centimeter, while that treated with chlorine showed 8,800 of the harmless bacilli to the cubic centimeter. The fact that the water samples have to be sent to Edmonton by train also permits the water to stand for a time, with the result that the propagation of bacilli is favored. The complete result of the analyses of water taken direct from the Bow River and the chlorinated water is as follows:—

	Direct from Bow River.	Chlorinated.
Hardness	120	114.2
Total solids	215	243
Loss on ignition	82	120
Alkalinity	132	120
Ammonia, free	.008	.026
Ammonia, albuminized	.032	.006
Nitrites	None	None
Nitrates	.04	.04
Chlorine	1.8	2.7
Sulphate	None	None
Colon bacillus	Negative	Negative

Edmonton, Alta.—City Engineer Latornell has submitted to the Commissioners blue prints showing the proposed sewage purification works to be erected on Ross Flats. As he pointed out, for some time past it has been proposed to erect a disposal plant there to purify the sewage from that portion of the city, which, roughly speaking, lies south of Jasper Avenue, between First and Twelfth Streets. In 1912 an appropriation of $30,000 was set apart for the construction of such a plant. But further study of the question has led Mr. Latornell to the conclusion that it would be an advantage if the city could bring across to this side of the river the sewage from that part of the South Side, which is already provided with drainage, and treat this South Side sewage in the plant located on Ross Flats. The new drawings are for that plant. A larger plant is in consequence required than was originally intended, but the ultimate economy in having one plant instead of two will be considerable, in the opinion of the city engineer, even though the new arrangement will necessitate one very expensive item, namely, a syphon under the river.

Ottawa, Ont.—On the suggestion of City Engineer Currie, a recommendation will be made to the city council by the board of control with a view to improving the manner of laying pavements. The main point aimed at is to prevent pavements sinking over where water or sewer pipes have been laid, and also to avoid having public services companies cut up a pavement the next day or so after it is laid. The proposition is that no permanent pavement be laid on any street till six months after the work has been passed by the city council. This will give the city time to do its underground work on the street and allow the earth used for filling in to settle. The public service companies will also be notified to do their work under the same conditions. The board discussed the matter, and all were agreed that the suggestion of the city engineer is a good one. So far, the Ottawa Gas Company has been cutting up pavements whenever it wished, claiming that under its charter it has a right to do so without asking the permission of the city. The board is of the opinion that recent legislation by the Dominion Parliament gives the municipality more control over the streets and prevents future work without the sanction of the city. At any rate, if the board's report is approved, the companies will be so notified.

Montreal, Que.—Chairman Drayton, of the Canadian Board of Railway Commissioners, and a small party recently witnessed a demonstration in London by the South Western Railway at Hamilton Court Station of the Prentice system of automatic wireless traffic control. It was invented by a young Canadian telegraphist, and is claimed to be an ideal scheme. The essential factor is that if any obstructive vehicle is on the track it interrupts wireless operations. A highly insulated wire is laid in the casing of the middle track. Normally, electric waves are constantly discharged, but the green and red signal lights are automatically shown when there is any danger on the track. The demonstration was entirely successful. A special train automatically was brought to a stop when a light engine was on the track some distance ahead. The cost of installation has not yet been indicated.

Vancouver, B.C.—An instrument that is expected to save the city of Spokane, Wash., $1,000 every day in the year by preventing a daily loss of 15,000,000 gallons of water from the system of mains, is being set up under direction of Water Superintendent Alexander Lindsay. It is a new leak detector, purchased by the department after a thorough investigation by Mr. Lindsay showed that 15,000,000 gallons of water was being lost each day by defects hard to locate in the complex system of underground mains. "We have just received the instructions for setting up the rather complicated piece of apparatus," Mr. Lindsay said. "The meter is attached to a single lead running into a given district, and all other inlets are cut off. It records every gallon of water sent into the pipes at the hour pumped. Then we trace the flow, and if it is found that much water is going into the district between the hours of 1 a.m. and 3 a.m., when the use of water is at the minimum stage, we can tell that there is a leakage. Then the district is made smaller, parts of it being cut off, until by a process of elimination we find just where the section is that is causing the waste. It will take some time to test out all of the mains in a city of 120,000 population, but our regular force will start the work immediately, and we hope to be able to reduce a great amount of waste in the very near future."

Quebec, Que.—Interesting forecasts of the business to be brought up at the next session of the Provincial Legislature, when a further loan for the good roads work, aid for the Canadian Northern Railway, in the Province of Quebec, and the question of a new court house for Montreal will be dealt with, were made by the Hon. Mr. L. P. Berard, Legislative Councillor, of Quebec, in an interview recently. The Highways Bill, passed in the early part of the year, authorized a loan of $10,000,000 for the improvement and building of roads in the province. About $3,000,000 of this has already been secured. So much work is in progress, however, says Mr. Berard, that more funds will be needed before long, and an additional loan floated towards the end of this year. Another important measure for consideration at the next session will be financial aid for the Canadian Northern Quebec lines. Mr. Berard does not anticipate any serious opposition in this matter, as he believes it to be generally recognized that the railway is entitled to the same benefits received by other great systems in the Dominion. Such assistance on the part of the Provincial Government will, of course, only provide for lines in the province. A proposition for the erection of Montreal's new court house, so long the subject of discussion, Mr. Berard states, will be introduced at the next session. The bench and bar of the city are practically unanimous on the question, and Sir Lomer Gouin is in favor of a new building also. Consequently, there is a good prospect of definite action being taken before the spring of 1914.

PERSONAL.

Geo. A. JANIN, city engineer of Montreal, is at present in Europe on a short vacation.

P. J. MITCHELL, of London, England, who organized The Canadian P. J. Mitchell Company about two years ago, is spending a few weeks at Banff, Alta.

C. A. MEADOWS, B.A.Sc., has acquired the management of the newly-opened Toronto branch of the Dominion Engineering and Inspection Company, of Montreal.

R. C. HARRIS, commissioner of works for Toronto recently received an offer from Vancouver, B.C., to a similar position there at a salary of $10,000 a year. Mr. Harris will likely remain with Toronto, however.

R. G. FINCH, of the State engineer and surveyor's staff, New York Barge Canal, has been spending a few days in Ontario acquainting himself with Canadian canal developments.

W. F. TELTZEL, provincial government agent a Nelson, B.C., has resigned his present position to accept the position of selecting and recommending sites for all public buildings throughout Western Canada. He will make his headquarters at Victoria.

OAKLEY T. BROWN, M. E., formerly combustion engineer on the Camden, N.J., engineering staff of R. D. Wood and Company, of Philadelphia, has been appointed chief engineer of The Mechanical Engineering Company, Limited, Montreal.

J. L. CHAMBERS, of Chambers, Limited, Toronto, has just returned from a business trip to Great Britain, while abroad Mr. Chambers visited the works of John Fowler and Company, Leeds, Manlove, Alliott and Company, Nottingham, Bertrams, Limited, Edinburgh and others of his principals over there.

HON. W. F. ALYMER, Dominion public works engineer at present in Vancouver, will go north shortly for the purpose of examining the Fraser River between Soda Creek and Lillooet with regard to the feasibility of navigation along this part of the river, and also to report regarding the channel in the south fork of the Fraser near Tete Jaune Cache.

FRANCIS A. JACOBS, the Montreal mechanical engineer who invented the Jacobs shop furnaces and oil burning equipment, has sold his patents and business to the Mechanical Engineering Company Limited, of Montreal. Mr. Jacobs becomes president of the new company. Mr. Graham being secretary-treasurer. The company has a well-equipped shop on Mill Street, Montreal. They are building furnaces and burners under the trade name of "Mecol," and are also agents for Canada for R. D. Wood and Company, of Philadelphia, and Mesta Machine Company, of Pittsburgh.

OBITUARY.

E. M. STOREY, a prominent architect residing in Regina, Sask., died on August 24th. Mr. Storey was formerly a resident of Kingston, Ont.

ALEXANDER MACFARLANE, D.Sc., LL.D., whose prominence as an educationalist in mathematical and physical research grew to be universal, died at his home in Chatham, Ont., on August 28th.

Dr. Macfarlane was born at Blairgowrie, Scotland, April 21st, 1851. He was a pupil-teacher at the age of thirteen, and in 1869 entered the University of Edinburgh, where he won many scholarships. In 1875 he finished an unusually extensive course in undergraduate study by taking the degree of M.A., with honors in mathematics and physics.

After graduation he won the MacLaren fellowship, and in 1878 he obtained the doctorate, after one year spent on botany, chemistry and natural history. His thesis was a remarkable experimental research into the conditions governing the electric spark. This brought him to the attention of the celebrated electrician and philosopher, Clerk Maxwell. In 1879 he was elected to the Royal Society of Edinburgh.

In 1885 he was called to the chair of physics in the University of Texas, and in 1887 received the honorary title of LL.D., from the University of Michigan. In 1891 he was actively engaged in organizing the Texas Academy of Science, and for two years acted as honorary secretary.

About fifteen years ago Dr. Macfarlane moved to this country, and since that time he has been actively engaged in mathematical research. A few months ago Dr. Macfarlane read a paper before the Royal Society of Britain that elicited much praise from its members. At a special invitation from President Falconer he gave, last spring, a series of five lectures on Vector Algebra at the University of Toronto. A brief of these lectures, written by Dr. Macfarlane, appeared in "Applied Science" for July.

Dr. Macfarlane lived in Chatham for the past nine years, during which time he took great interest in educational matters.

COMING MEETINGS.

THE NEW ENGLAND WATERWORKS ASSOCIATION.—Annual Convention to be held in Philadelphia, Pa., September 10th, 11th and 12th, 1913. Secretary, William Kent, Narragansett Pier, R.I.

THE ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Sixth General Annual Assembly will be held at Calgary, Alberta, September 15th and 16th. President, J. H. G. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

NATIONAL PAVING BRICK MANUFACTURERS' ASSOCIATION.—Tenth Annual Meeting will be held at Cleveland, Ohio, September 17th and 18th. Secretary, W. P. Blair, 824 Engineers' Building, Cleveland, Ohio.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Third Annual Meeting in Regina, September 18th, 19th and 20th. General Secretary, Major Lorne Drum, Ottawa; Local Secretary, R. H. Murray, C.E., Regina.

ILLUMINATING ENGINEERING SOCIETY.—Annual Convention to be held at Pittsburg, Pa., September 22nd to the 26th. Secretary, I. D. Israel, 29 West 39th Street, New York City.

AMERICAN ROAD CONGRESS.—Annual Session will be held in Detroit, Michigan, from September 29th to October 4th. Secretary, J. E. Pennybacker, Colorado Building, Washington, D.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—Twentieth Annual Meeting to be held in Wilmington, Del., October 7th to 10th. Secretary, A. Prescott Folwell, 15 Union Square, New York.

UNITED STATES GOOD ROADS ASSOCIATION.—Convention will be held at St. Louis, Mo., November 10th to 15th. Secretary, J. A. Rountree, Lo21 Brown-Marx Building, Birmingham, Ala.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

ORDERS OF THE RAILWAY COMMISSIONERS
OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

20043—August 12—Refusing application of board of trade of Lethbridge against cancellation of G.N.R. tariff, C.R.C. No. 720, applying between stations on various lines in Eastern Canada, and stations on the Alberta Railway and Irrigation Company's Railway.

20044—August 13—Authorizing C.P.R. to revise a portion of the present main line of its Farnham Subdivision and to construct additional track across Central Vermont Railway.

20045—August 14—Amending Order 19803, July 17th, 1913, in re C.P.R. crossing at mileage 9.7 from Aylmer, by striking out the word "Aylmer" and substituting the word "Hull."

20046—August 5—Authorizing C.N.R. to construct spur to premises of Mackenzie Ellis Company, Prince Albert, Sask.

20047—August 8—Directing C.P.R. to reduce its rate on coal from Port Burwell to Lambton and Islington from 75 cents to 70 cents per ton; effective not later than September 1st, 1913.

20048—August 13—Amending Order No. 19946, dated July 31st, 1913, re C.P.R. crossing G.T.R. at Tecumseh Street, Toronto, by striking out the words "or construction purposes only."

20049—August 13—Amending Order 4669, dated April 15th, 1908, in re Toronto and Niagara Power Company carrying its wires across C.P.R., in Lot 6, Con. 3, Twp. of York, by providing that crossing be made in accordance with plan on file with the Board under File No. 22682; subject to supervision of the Board's Electric Engineer.

20050—August 1—Approving proposed alteration by C.L.O. and W. of its line in the Twp. of Camden, at mileage 45.5, so as to include extra lands required for station grounds.

20051—August 12—Amending Order No. 19239, dated May 9th, 1913, re protection at King Street, by providing that the whole cost of the flagman maintained at said crossing be paid by G.T.R.

20052—August 12—Authorizing G.T.R. to construct two branch lines to premises of Riordon Pulp and Paper Company, Hawkesbury.

20053—August 14—Authorizing G.T.R. to renew bridge No. 5, on the 15th District, Middle Division, King Street, Toronto.

20054—July 29—Authorizing G.T.R. B.L. Co. to cross Harry and Francis Streets, in the city of Calgary.

20055—August 9—Approving plans and specifications of proposed repairs to Little Creek Drain, filed by G.T.R., in the Tp. of Tilbury North.

20056—August 12—Rescinding Order No. 5390, dated August 13th, 1908, in re application of Alex. Pilon, of Casselman, Ont., declaring a charge of $3 per car to be made by G.T.R. for switching at Casselman.

20057—August 13—Directing C.N.R. to fence its right-of-way on its Rossburn Branch from mileage 35 to mileage 40, Manitoba; work to be completed by September 1st, 1913.

20058—August 11—Authorizing Wm. Alexander, of Silverwood, Sask., to construct spur across C.N.R. to N.E. ¼ of Sec. 15, Tp. 37, Rge. 5, and N.W. ¼ of Sec. 14, Tp. 37, Rge. 5, W. 3 M., Mun. of Cory, Sask.

20059—August 7—Amending Order No. 18616 in re public road between Cons. 12 and 13, Tp. of Chisholm, by approving of proposed diversion shown on plan, filed by the Railway Company.

20060—August 13—Authorizing C.N.O.R. to cross and divert public road in Lot 38, Con. 18, Tp. of Ferris.

20061—August 13—Authorizing C.N. B.L. Co. to cross thirty highways on its Grosse Isle Branch.

20062—August 13—Approving location of station grounds of Inter-provincial and James Bay Railway Company, at mileage 9.56, Parish of Mercier, Que.

20063—August 11—Approving terms and conditions of Bell Telephone contract forms 1 and 2, in so far as they restrict or limit telephone company's liability.

20064—August 13—Authorizing the St. Lawrence Pulp and Lumber Corporation to cross Atlantic, Quebec and Western Railway in the County of Gaspe.

20065—August 12—Authorizing G.N.R. to remove frog and switch at crossing at Crescent, B.C., and to construct a new switch thereat.

20066—August 15—Authorizing C.P.R. to construct spur for J. Gunn and Sons, Winnipeg, Man.

20067—August 15—Authorizing C.P.R. to reconstruct bridge No. 5.7 over Mill Street, Norwood, Ont.

20068—August 15—Authorizing C.N.R. to construct spur for Manitoba Gypsum Company, near Moosehorn.

20069—August 12—Authorizing C.N.R. to construct branch line through Block 6, Hudson Bay Reserve.

20070—August 15—Authorizing G.T.P. B.L. Co. to cross 14 highways in the town of Battleford, Sask.

20071—August 15—Approving clearance of coal conveyer on C.P.R. at sidings of Ontario National Brick Company, Limited, Twp. of Toronto.

20072—August 14—Authorizing Bell Telephone Company to construct wires and poles upon twenty-one streets in the city of Montreal, for the purpose of operating its telephone service.

20073—August 15—Approving proposed Scale "P" to the Express Classification for Canada.

20074—August 12—Amending Order No. 17384 to provide charges for cream up to 400 miles, as follows:—

Miles.	Five-gallon cans, each.	Eight-gallon cans, each.	Ten-gallon cans, each.
350	71 cents	91 cents	96 cents
400	79 cents	101 cents	106 cents

to become effective not later than September 18, 1913.

20075—August 15—Authorizing the C.N.O.R. to construct a temporary level crossing over public road between Cons. B. and 2, Twp. Westmeath.

20076—August 14—Authorizing the C.P.R. to construct siding tracks across St. Roch St., Quebec, St. Peter's Ward, P.Q., to storage yard, at mileage 159.8 from St. Martin Jct., on the C.P.R. line, Eastern Div., Dsitrict No. 3, Quebec Sub-division.

20077—August 15—Approving location of the C.N.O.R. station grounds at Westmeath, Twp. Westmeath, mileage 79.64 from Ottawa.

20078—August 19—Authorizing C.P.R. to construct three extra tracks across Jamieson St., in the town of Lacombe, Alta, by means of grade crossings.

20079—August 15—Authorizing the C.P.R. to revise the grade of the present grade crossings, necessitated by an additional track (double track); and to construct additional track across certain highways between mileage 10.00 and mileage 39.1, London Sub-division.

20080—August 18—Approving proposed location of C.P.R. station on Lot 2, 7th Con. of the Twp. of Cavan, Co. Durham, Ont., at mileage 38.66 on its Toronto Sub-division at Bethany Jct.

20081—August 18—Amending Order No. 19939 by striking out paragraph 2 of the Order and substituting therefor the following:—

(Continued on Page 84).

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

▲—Denotes an item regarding work advertised in *The Canadian Engineer*.
✚—Denotes contract awarded. The names of successful contractors are set in CAPITALS.

PLANS AND SPECIFICATIONS ON FILE.

RAILWAYS—STEAM AND ELECTRIC.

Derby Junction, N.B.—Tenders will be received up till the 19th of September, 1913, for the diversion of line Nelson to the Junction. Plans and specifications may be obtained from the Chief Engineer, Moncton, N.B., and Department of Railways and Canals, Ottawa. J. K. Jones, secretary.

Edmonton, Alta.—The work of ballasting the main line of the Canadian Northern Railway between Edmonton and Tollerton, the first division point west of the city, is progressing rapidly and it is expected the line will be ready to turn over for operation by the middle of September. It is the intention of the company to operate a tri-weekly service between Edmonton and Tollerton as soon as the road is completed.

Fort William, Ont.—At the last meeting of the city council it was decided that all efforts possible would be made to have the street railway extensions across the Kaministiquia River to island No. 2, completed and in operation before the end of the present year, which will assuredly be a great accommodation for the many workmen employed on the various industries in this locality.

St. Malo, Que.—Tenders will be received up till the 9th of September, 1913, for the construction of locomotive and car shops. Plans and specifications may be obtained from Board of Commissioners of the Transcontinental Railway, Ottawa. P. E. Ryan, Secretary.

Toronto, Ont.—Mayor Hocken expects that the experts who are appraising the value of the Toronto Street Railway and Toronto Electric Light Companies' assets will be ready about the end of the week.

Victoria, B.C.—Mr. Hall, general manager of the western lines of the Canadian Pacific Railway, stated that the locomotives on the Cascade subdivision of the line would be transformed into oil burners and would be ready for service under the new system by the end of October, or even earlier. The railway is establishing oil tanks at different divisional points to supply the engines with fuel. Freight, passenger and yard locomotives will use oil as fuel. Commenting on the double track operations, Mr. Hall said that gratifying progress was being made and that trains would be running on the new track at an early date between Mission and Ruby Creek. The general manager observed also that the company had completed its preparations for handling the grain crop, which he believed from the estimates would be very good. He added that the reported damage in some of the prairie sections was only slight.

✚—**Vancouver, B.C.**—The Kettle Valley Railway Company has awarded MacARTHUR BROTHERS COMPANY, New York, the contract for the construction of the 38-mile section of the railway between the summit of the Hope Mountains and the town of Hope. The contract price is $3,000,000.

Welland, Ont.—The Dunnville, Wellandport and Beamsville Electric Railway, which has been under construction for some years, but which lately has not been progressing on account of financial difficulties, is now about to be started again, arrangements being completed for the sale of extra bonds. Thirteen miles are already graded and ties laid on this part of the road, the bridges and structural work being also completed on this division. The line has a charter from Port Dover to St. Catharines, with branches to Dunnville, Welland, Jordan Harbor and other points, making train connections with the G.T.R., Wabash, Michigan Central, and Toronto, Hamilton and Buffalo. It runs through a good section of the country, and when in operation will no doubt be a great success.

BRIDGES, ROADS AND PAVEMENTS.

▲—**Cayuga, Ont.**—Tenders will be received up till the 16th of September, 1913, for the construction of 26½ miles of stone macadam road. Plans and specifications may be obtained from T. A. Snyder, County Clerk.

Barrett Specification Roofs

Economy *and* Protection

THE fire standards for theatre buildings are especially rigid. It is significant, therefore, that a large number of theatres throughout the country carry Barrett Specification Roofs. These roofs take the base rate of insurance and are acceptable to fire underwriters everywhere

Their cost is less than that of any other permanent roof covering; they require no expenditure whatever for maintenance and usually last about twenty years.

A Barrett Specification Roof consists of five plies of tarred felt and pitch with a top covering of slag, gravel or tile. Being one continuous sheet with no laps or seams it blankets the flames in case of fire and will last until the supports beneath are entirely destroyed. From the standpoint of both economy and protection such roofs should be used on all permanent buildings.

A copy of the Barrett Specification with tracing, ready for incorporation into your building plans sent free on request. Address nearest office.

Special Note

We advise incorporating in plans the full wording of The Barrett Specification, in order to avoid any misunderstanding.

If any abbreviated form is desired, however, the following is suggested.

ROOFING — Shall be a Barrett Specification Roof laid as directed in printed Specification, revised August 15th, 1911, using the materials specified and subject to the inspection requirement.

Danville, Ont.—Tenders will be received up till the 6th of September, 1913, for the erection of a single-span bridge at Nicolet Falls. Plans and specifications may be obtained from C. C. Brown, secretary-treasurer.

Fredericton, N.B.—Tenders will be received up till the 8th of September, 1913, for the construction of a public highway from McAdam Junction to Havery settlement a distance of about nine miles. Plans and specifications may be obtained from the Department of Public Works, Fredericton, N.B.

Guelph, Ont.—Mr. C. H. Mitchell, consulting engineer, Toronto, has examined and approved of the plans prepared by City Engineer Holland for the alterations to the Neve Street bridge and the Sewerage and Public Works Commission will commence work for an additional span and a 200-foot retaining wall as soon as possible. It is expected that when completed it will put an end to the spring floods have done thousands of dollars' damage in the city the last two years.

Halifax, N.S.—Tenders will be received up till the 11th of September, 1913, for the construction of bridges and culverts in the County of Lunenburg. Plans and specifications may be obtained from the Department of Public Works, Halifax, N.S. E. H. Armstrong, Commissioner.

Hamilton, Ont.—The McKittrick Syndicate is planning the erection of a $100,000 bridge in the southwestern portion of the city to connect with the McKittrick Syndicate survey.

+—Kansas City, Mo.—The DOLARWAY PAVEMENT COMPANY has been awarded the contract for the construction of 16,000 square yards of pavement. The contract price is not given.

▲—London, Ont.—Tenders will be received up till the 11th of September, 1913, for the supply and erection of three 130 feet spans riveted truss steel highway bridges over the Thames River. Plans and specifications may be obtained from Wm. N. Ashplant, City Engineer.

Montreal, Que.—Headed by alderman Houle, a delegation of residents of St. Denis ward called on the controllers recently and asked that the work of levelling and paving the eastern side of St. Denis street be carried out as soon as possible. The commissioners promised to recommend to the council that the work which will cost $27,000, be immediately got under way.

+—Montreal, Que.—The Board of Control has awarded the following paving contracts amounting to $330,067: To the BITHULITHIC PAVING COMPANY, Sherbrooke St., from Champlain to St. Denis Street, at $2.75 a square yard for $72,117.50; Sherbrooke Street from St. Denis to McGill College at $2.78 a square yard, $74,870; Durocher Street from Prince Arthur to Pine Avenue at $2.75 a square yard, $4,812.50; St. Hubert Street from Ontario to Sherbrooke street, at $2.84 for $6,665.48; and Union Avenue, from Sherbrooke to Burnside Street, at $2.88, for $7,056, making a total to this company of $165,521.49. To the WARNER QUINLAN ASPHALT COMPANY, Sherbrooke Street from McGill College to Guy Street, at $2.95, $67,810; St. Andrew Street from Dorchester Street to Laugauchetiere Street, at $2.82 for $3,553.20; Ontario Street from Sherbrook Street to Burnside at $2.87 for $6,084, and MacGregor Street in all its length at $2.91 for $11,640, making a total of $89,087.20. To the SICILY ASPHALTUM PAVING COMPANY, partly in asphalt: Aylmer Street, Sherbrooke to St. Catherine Street, asphalt, at $2.53 and special paving at $2.83, for $9,213.33; McGill College Avenue, from Sherbrooke to St. Catherine Street, asphalt at $2.53, and paving at $2.80, for $11,355.60; Beaudry Street, from Ontario to Sherbrooke Street, asphalt at $2.54; special paving at $2.80, for $9,345.51; Champlain Street, from Ontario to Sherbrooke Streets, asphalt at $2.35 and special paving at $2.85, for $14,019.15; City Councillors Street, from St. Catherine to Sherbrooke Street, asphalt at $2.54 and special paving at $2.78, for $8,593.68; St. Charles Borromee from St. Catherine Street to Sherbrooke Street, asphalt at $2.53 and special paving at $2.80, for $11,434.18; and St. Urbain Street, from Demontigny to Sherbrooke, asphalt at $2.54 and paving at $2.83, for $11,497.46; making a total of $75,458.91.

+—Ottawa, Ont.—The Electrical Commission has awarded the IMPERIAL WIRE AND CABLE COMPANY, Montreal, the contract for supplying wire cable required for the conduit work.

Saskatoon, Sask.—President Walter C. Murray, M.A., LL.D., recently turned the first sod in connection with work on the new traffic bridge which will connect the University with the city. It will be the largest reinforced concrete bridge in Canada, and will cost $450,000.

Wynyard, Sask.—Three new bridges are to be constructed by the Highway Commission this season. Two will be steel of forty feet span with concrete abutments. With the construction of these bridges and the completion of road work in progress considerable improvements will be effected.

LIGHT, HEAT AND POWER.

+—Carlyle, Sask.—The town has awarded the following contracts in connection with the waterworks and electrical lighting plants:—Brick power-house building, and reinforced concrete reservoir, BENNETT, DEBNAM CO., Calgary; return tubular boilers, stack, steam piping, WATEROUS ENGINE WORKS CO., high speed vertical engine, GOLDIE & McCULLOCH CO.; air-lift pumping system and compressor, CANADIAN INGERSOLL-RAND COMPANY; compound duplex service pump, J. McDOUGALL CALEDONIAN IRON WORKS COMPANY; alternator and switchboard, (for Swedish generator), GENERAL SUPPLIES, LIMITED, Calgary; copper wire, E. F. PHILLIPS ELECTRIC CO., Montreal; transformers, CANADIAN MALONEY ELECTRIC CO.; line erection, E. SMITH ELECTRIC CO., Melville, Sask. John Galt Engineering Company, Winnipeg, are the consulting engineers.

+—Hamilton, Ont.—The Board of Control has awarded Mr. G. M. Guest, Montreal, the contract for the laying of the underground conduit system. The contract price is $177,822. Other firms tendered as follows: F. F. Ley and Company, Springfield Mass., $180,371; H. E. Fox, New York, $292,806, and J. W. Turner, Des Moines, Iowa, $197,366.

+—Montreal, Que.—The Board of Control has awarded Mr. G. M. GUEST the contract for the construction of conduits along Bleury Street from Craig to Pine Avenue, and for the second section of St. Catherine Street from Guy Street to Atwater Avenue, the contract price in the first case being $58,000, and in the second $35,000.

▲—Neepawa, Man.—Tenders will be received up till the 12th of September, 1913, for supplying machinery for additions to the power plant. Plans and specifications may be obtained from *The Canadian Engineer's* offices at Winnipeg, Toronto, and Montreal; W. E. Skinner, Limited, Consulting Engineers, Winnipeg, and J. W. Bradley, Secretary-Treasurer.

Ottawa, Ont.—Tenders will be received up till the 10th of September, 1913, for supplying 95 ornamental iron posts and fittings. Specifications may be obtained from J. E. Brown, electrical superintendent.

Port Arthur, Ont.—The Canadian Northern Railway is about to install electric apparatus for the operation of the big elevator plant in this city, according to information received. Commissioner Hackney has been on a campaign of late endeavoring to get manufacturers in the city to use electricity in lieu of steam and eventually he has succeeded. The new government elevator is to use power and now comes the announcement that the largest elevator in the world is to fall in line with the others in this respect. It is estimated that with the additional unit to be constructed to the elevator in the near future, the plant will require from 1,100 to 1,500 horsepower.

▲—Regina, Sask.—Tenders will be received up till the 1st of October, 1913, for supplying equipment for power-house. Plans and specifications may be obtained from E. W. Bull, Superintendent of Light and Power Commission.

Toronto, Ont.—At the meeting of the Hydro-Electric Commission recently it was decided to allow the St. Thomas-Windsor extension of the power line to follow the most southerly of the four routes proposed, and pass through St. Thomas, Ridgetown, Rodney, Dutton and intermediate points. The route selected will allow the cheapest and easiest construction, and will be in proximity to the line of the Michigan Central Railroad. Construction work on the new line will be commenced at once. It is not known just what the scheme will cost, but there is little doubt that it will mount into the millions. There were many influences exerted to cause the commission to choose one of the several

48 in CONTINUOUS STAVE LINE.

MANNESMANN TUBE CO., LIMITED

BOOKLETS ON REQUEST **59 Victoria Square, MONTREAL**

other proposed routes, but the one decided on will serve the largest area and most thickly populated district. The entire line is 112 miles in length and the commission will construct it.

+—**Victoria, B.C.**—The Pelton Water Wheel Company has awarded MR. ALBERT KELLEY, Seattle, the contract for supplying two miles of welded steel pressure pipes ranging from 48-in. to 54-in. in diameter, for the hydro-electric plant at the Jordan River.

+—**Winnipeg, Man.**—The Board of Control has awarded the CANADIAN WESTINGHOUSE COMPANY the contract for supplying three generators for the municipal power house at Point du Bois. The contract price is $103,800. There were five other tenders submitted.

GARBAGE, SEWAGE AND WATER.

+—**Ottawa, Ont.**—The city council has awarded Messrs. LOMIS, McBEAN & WILLIAMS the contract for the lifting, repairing and relaying of the old intake pipe. The work will be commenced at once.

Ottawa, Ont.—Tenders will be received up till the 6th of September, 1913, for the material required in connection with the relaying of the 40-inch steel clear pipe. Plans and specifications may be obtained from Arch. Currie, City Engineer.

Winnipeg, Man.—Winnipeg's permanent water supply from Shoal Lake will cost $13,045,000, and it will take at least five years to install, according to the formal report of the consulting experts read recently before the administration board of the Greater Winnipeg water district by Mayor Deacon, of Winnipeg. The report was adopted and the work will proceed at once, although definite action was deferred by the board for one week to enable the members to study details. Part of the plan is for a great uncovered reservoir at Transcona, eight miles east of Winnipeg, to hold 250,000,000 gallons. Gravity will carry the water to this reservoir, from where it will be pumped into Winnipeg with sufficient pressure to deliver it at the householder's tap.

Winnipeg, Man.—Tenders will be received up till the 19th of September, 1913, for supplying cast-iron water pipe and hydrants. Plans and specifications may be obtained from the Board of Control. M. Peterson, secretary.

INDUSTRIAL WORKS.

Amherst, N.S.—Tenders will be received up till the 22nd of September, 1913, for the extension of a wharf. Plans and specifications may be obtained from District Engineers, T. G. Locke, Shelbourne, N.S., and C. E. W. Dodwell, Halifax, and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

London.—The first of the mammoth dredgers left Gravesend recently to work on the twelve million dollar contract for the Courtney dock at St. John, N.B. She is self-propelling and with fair weather will take three weeks in crossing. Her capacity is a thousand tons an hour. A second dredger will leave Holland next month and a third will go from the Argentine.

Meaford, Ont.—Tenders will be received up till the 29th of September, 1913, for the construction of an extension and repairs to the revetment wall here. Plans and specifications may be obtained from District Engineers, J. G. Sing, Toronto, and J. H. Armstrong, Midland, and the Department of Public Works, R. C. Desrochers, Secretary.

+—**Prince Rupert, B.C.**—The Edward Townsite Co., Limited, has awarded MESSRS. RITCHIE, AGNEW & CO. the contract for the construction of a crib dam, and supplying and laying 10,400 lineal feet of wood stave pipe.

+—**San Francisco, Cal.**—The MacARTHUR CONCRETE PILE & FOUNDATION CO., New York, has been awarded the contract for covering the concrete pile foundation for the new United States Sub-Treasury Building.

+—**Toronto, Ont.**—The Board of Harbor Commissioners have awarded the CANADIAN STEWART COMPANY, Montreal, the contract for dredging the harbor. The contract price was 19½ cents per cubic yard, or approximately $5,500,000. Other firms tendered as follows:—Tilbury Dock & Dredging Company, London, England, 24½ cents per cubic yard, $7,521,500. Sir John Jackson, London, England, 20½ cents per cubic yard, $6,293,500. Pearson & Company, Incorporated, London and New York, slightly over 20 cents per cubic yard, approximately $6,000,000. Sherman, Stalter Company, New York, tendered on a portion of the work, slightly over 20 cents per cubic yard. The total number of cubic yards to be dredged is slightly less than 30,700,000. The work will be commenced about March, 1914, and will take eight years to complete. The successful tenderers will have to construct two new dredges which will be amongst the largest in the world. In the meantime they will use a number of dredges which have been employed on the New York State barge canal.

Vail's Point, Ont.—Tenders will be received up till the 15th of September, 1913, for the construction of a wharf. Plans and specifications may be obtained from District Engineers, J. G. Sing, Esq., and J. H. Armstrong, Esq., Midland, and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

+—**Victoria, B.C.**—The P & O Steamship Company has awarded Messrs. CAMMELL, LAIRD & COMPANY the contract for two passenger steamers of the new Khiwa class. These ships will be of 9,000 tons gross register, length 480 feet, breadth 58 feet, depth 33 feet, with spacious accommodation for about 150 saloon passengers. They are chiefly intended for the company's Indian trade, and will, for vessels of their type, be powerfully engined.

+—**Victoria, B.C.**—The Peebles Explosives, Limited, has awarded MESSRS. CULLINTON BROS. the contract for the erection of a wharf in connection with the company's buildings on James Island.

Winnipeg, Man.—Tenders will be received up till the 8th of September, 1913, for the interior decorations for the King Edward Hospital. Plans and specifications may be obtained from Board of Control, M. Peterson.

MISCELLANEOUS.

Calgary, Alta.—The first unit of Calgary's 20,000,000 bushel internal elevator, which the government proposes to build here, will cost $1,500,000 and have a grain capacity of 3,500,000 bushels. It will be a duplicate of the big internal elevator which the government purposes building at Saskatoon.

Calgary, Alta.—The by-laws upon which the ratepayers of Calgary will be called to vote on September 27th will provide for the expenditure of $2,333,440. There will be 16 money by-laws. All will be submitted on the one day. The money by-laws to be voted on are as follows:—$52,000, fire department; $45,100, parks and cemeteries; $250,000, erecting, equipping, and constructing industrial building; $60,000, Hillhurst athletic grounds; $350,000, union stock yard purposes, etc.; $19,250, paving, curb and gutter, Boulevard, N.E.; $468,900, high level concrete bridge across Bow River at Centre Street; $173,000, concrete bridge across Bow River at Ninth Street West; $319,350, concrete bridge at Fourth Street West; $82,100, steel bridge across Bow River at Fifteenth Street East; $82,500, concrete bridge across Elbow River at Fourth Street West; $173,000, concrete bridge across the Bow River at Fourteenth Street West; $10,000, straightening Elgin Avenue and Second Avenue northwest; $155,000, Lowry Gardens; $63,140, trunk sewer at Ogden; $30,000, hospitals, tubercular

Edmonton, Alta.—The Bank of British North America will erect a three-story bank building. The estimated cost is $150,000.

Grosse Isle, Que.—Tenders will be received up till the 8th of September, 1913, for foundations for the infectious diseases hospital. Plans and specifications may be obtained from District Engineers J. A. Tremblay, Montreal, and Charles Chapais, Quebec, and the Department of Public Works, Ottawa. R. C. Desrochers, Secretary.

London, Ont.—A fire occurred on August 29 a week before the opening of the Western Fair, which destroyed five of the exhibition buildings to the extent of $50,000. The work of rebuilding has commenced.

The Hampton Sedimentation Tank

Used in connection with an electrolytic hypochlorite treatment, the process is ABSOLUTELY ODORLESS and the effluent is free from disease germs.

Nine years of operation in large and important installations in England have demonstrated that an effluent exceptionally low in suspended solids and as free from odor as the entering sewage may be obtained with The Hampton Tank.

The Hampton Tank reduces the cost of any subsequent treatment.

Write for leaflet showing construction of the tank and explaining the special features of its design which make it particularly successful. This tank is not an experiment. It has been used for nine years with most satisfactory results, and has **PROVED** its efficiency and economy.

Leaflet on request.

Sterilization Co.

Union Building, Clinton Street

NEWARK, N.J.

Also engineers for the electrolytic treatment of water.

+—**Medicine Hat, Alta.**—The city council has awarded Messrs SACKRIDER & TURNER the contract for the erection of an electrical sub-station at Ogilvie Mills. The contract price was $9,900. Three other firms tendered, all over $10,000.

+—**Montreal, Que.**—The Canadian Vickers Co., Limited, has awarded the MacARTHUR CONCRETE, PILE & FOUNDATION CO., New York, the contract for the foundations of the new shipbuilding plant. About 750 pedestal concrete piles will compose the foundation.

▲—**Ottawa, Ont.**—Sketch designs in a preliminary competition for the erection of departments and courts buildings, will be received up till the 2nd of January, 1914. Conditions for both competitions may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Prince Rupert, B.C.—Tenders will be received up till the 23rd of September, 1913, for the construction of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence, Ottawa. Eugene Fiset, Deputy-Minister.

Sault Ste. Marie.—Following the partial destruction by fire of the big power plant of the Lake Superior Corporation after the big building had been struck by lightning, 1,100 men are idle while the repair gangs and electricians are working under pressure to get matters into shape for another start. It is hoped that a big portion of these men will be able to resume in a few days, but several hundreds will be idle for at least two weeks. The damage will run into many thousands of dollars.

+—**Vancouver, B.C.**—Messrs. E. J. RYAN & COMPANY have been awarded the contract for the erection of a new opera house on Pender Street. The contract price is $400,000.

+—**Vancouver, B.C.**—The Irish Fusilier Regiment has awarded Messrs. PERRY & FOWLER the contract for the erection of a new drill hall. The contract price is $200,000.

Vancouver, B.C.—The Dominion Government has prepared plans for the erection of a new immigration building. The estimated cost is $300,000.

Vancouver, B.C.—The following will be expended by the city council during the ensuing year: General hospital, $10,000; sewers, $100,000; rocking, planking and grading streets and lanes, $75,000; waterworks extensions, $300,000; park improvements, $25,000; exhibition committee, $35,000; opening and grading streets in Ward Seven, $15,000; Mountain View cemetery, $5,000; east end police station, $3,000; North Vancouver ferry subway, $17,000; creche, $20,000; schools, $158,000; Georgia-Harris bridge, $200,000; police headquarters, $75,000.

+—**Vernon, B.C.**—MR. T. A. ROBLEY has been awarded the construction of a three-story hotel. The contract price is $25,000.

Victoria, B.C.—Tenders will be received up till the 15th of September, 1913, for the erection of Somenos school. Plans and specifications may be obtained from the Department of Public Works, Victoria. J. E. Griffiths, Public Works Engineer.

+—**Victoria, B.C.**—The School Board has awarded MESSRS. DINSDALE & MALCOME the contract for the erection of a High School. The contract price is $400,000.

Victoria, B.C.—Tenders will be received up till the 15th of September, 1913, for the erection of Colwood school. Plans and specifications may be obtained from the Department of Public Works, Victoria. J. E. Griffiths, Public Works, Engineer.

Welland, Ont.—The building permits for the month of August amounted to $38,100. For the same month last year they amounted to $20,550. This is an increase of $17,550. D. T. Black, town engineer.

CURRENT NEWS.

Panama.—The blowing up of the Gamboa dike, which will remove the last obstruction to the navigation of the Panama Canal by light draught vessels, has been set for September 6. A flooding of the 5,000 foot section of the canal between the Miraflores locks and the Gamboa dike by diverting into the newly excavated pit the water from a nearby stream was begun August 23. It is desired to fill the pit nearly to a level with the open water in the channel on the other side of the dike, in order that the steam shovels may remove the material of the barrier after blasting, with facility. On this account it was deemed advisable to delay for a brief period the destruction of the dike. The pit is filling slowly and sea water probably will be admitted to hasten the process. The lower gates of the Miraflores locks have been permanently closed to prevent flooding of the lock chambers.

Toronto, Ont.—The purchase of two steamships for the Atlantic trade and two steamships for the Pacific coast service is announced by Sir Thomas Shaughnessy, president of the Canadian Pacific Railway, in the annual report just issued, which also brings out the additional lines to be constructed by the Canadian Pacific Railway this year. For the Atlantic trade the two vessels are to be of the intermediate type, 500 feet long, 64 feet beam, 11,600 gross tonnage, 15 knots speed, and to cost about a million and a half dollars each. The steamers to be acquired for the Pacific coast service are to be 395 feet long, 54 foot beam, and capable of making 22½ knots per hour at sea, and to cost approximately a million dollars each. It is the intention of the Canadian Pacific Railway to use the two Atlantic steamships for second and third-class passengers and freight traffic between European ports and Canada. The Pacific coast steamers are to be placed in the service between Vancouver, Victoria and other ports on the Pacific coast.

PATENTS.

Below will be found a complete list of patents recently granted to inventors in Canada and United States which is furnished by Messrs. Fetherstonhaugh and Company, patent barristers, solicitors, etc., head office, Royal Bank Building, 10 King Street East, Toronto. Offices in Hamilton, Montreal, Ottawa, Winnipeg, Vancouver and Washington, D.C., from whom all information may be readily obtained.

United States Patents.—C. Bellemare, tire-protectors; E. Danforth, horse blanket fasteners; P. E. Dcolittle, adjustable hangers; S. D. Hansen, insect collecting machines; F. A. Nugent, sod pulverizing machines; C. A. Tuerk, concrete mixer; J. C. Tweedale, pen-holder: T. L. Wilson, manufacturing an ammonium superphosphate fertilizer.

Canadian Patents.—F. C. Peck, outlet boxes; W. M. Shores, stoves; A. W. Anderson, flexible films; H. Ashbee, combined-key-rings and pouches; E. S. Aubry, compositions of matter for water-proofing; H. O. Blayney, joints for concrete structures; F. W. Bull, pneumatically-operated player pianos; F. W. Bull, expression controlling devices for player pianos; N. Champagne, ventilators; A. W. Crane, horse shoes; W. M. Day, tooth-ache easers; H. Hillard, horse shoes; W. J. Holmes, saw setting machines; A. W. Kemp, horse shoes and calks therefor; L. N. Lymburner hose hoisting and hanging devices; D. A. L. McDonald, street cars; E. S. Manny, hot water heaters; F. P. Murphy, display racks; F. W. M. A. Schneider, electric cartridge fuses; C. E. Stewart, warm air registers; A. Stoddard, lacing hooks; A. Wait, needle valves.

THE SUPPLY OF EMERY.

The world's supply of emery comes from Greek islands and from Asia Minor, near Smyrna. Importations to America, which average $250,000 annually, have been hampered within the past year because of disturbed conditions in the Balkans and the withdrawal from industrial life of so many men for the armies. Some American manufacturers have been inconvenienced by the delay in emery shipments.

It is announced that both the Canadian and the United States Governments will be officially represented at the third American Road Congress, in session in Detroit during the week of September 29th.

The Departmental House for Mechanical Goods HAS ARRIVED

What the department store is to the general public our "Mechanical Goods Departmental House" is to the engineering and contracting field.

The public takes the efficient and time-saving merchandising methods of the department store as a matter of course. In the mechanical world we offer the same convenient service.

Why lose time "shopping" around town when you can buy anything you want and of a standard quality all under "one roof"?

Our business is divided into a number of departments in order that it may be handled most expeditiously and to the best interests of our customers.

In addition to the staple articles pertaining to each department we handle a great many specialties, some of which are listed below.

SCALE DEPARTMENT
- Fairbanks World-famous Scales, of all types and sizes

VALVE AND STEAM GOODS DEPARTMENT
- Fairbanks Brass and Iron Valves
- Pratt and Cady Valves
- Foster Reducing Valves
- American Steam Pressure Gauges
- Wainwright Joints
- Penberthy Oilers
- Strong Steam Traps
- Wainwright Heaters
- Burt Exhaust Heads
- American Safety Valves
- Trident Water Meters
- Palmetto Packing
- Durabla Packing
- Oster Stocks and Dies
- Tools and Fittings

ENGINE DEPARTMENT
- Fairbanks-Morse Oil Engines
- Fairbanks-Morse Marine Engines
- Fairbanks-Morse Tractors
- Farm Machinery
- Motor Boat Supplies
- Automobile Supplies

PUMP DEPARTMENT
- Fairbanks-Morse Steam Pumps
- Power Pumps
- Goulds Power Pumps
- Hand Pumps
- Combined Engines and Pumps
- Spraying Outfits
- Air Compressors
- Suburban Water Systems

ELECTRICAL DEPARTMENT
- Fairbanks-Morse Generaters and Motors
- Edison Storage Batteries
- Suburban Lighting Outfits

MACHINERY DEPARTMENT
- Pratt and Whitney Tools
- Brown and Sharpe Tools
- McDougall Lathes
- Bertram Tools
- Machine shop tools of all kinds
- Wood Working Machinery

TRANSMISSION DEPARTM'T
- Fairbanks Wood Split Pulleys
- Universal Giant Shaft Hanger
- Skefko Ball Bearings
- Nicholson Couplings

RAILWAY AND SUPPLY DEPARTMENT
- Fairbanks-Morse Motor Cars
- Elwell-Parker Trucks
- Barrett Jacks
- Arthur Koppel Industrial Ry. Equipment
- Fairbanks-Morse Air Compressors
- Fairbanks-Morse Hoisting Engines
- Fairbanks Trucks
- Milburn Lights
- Smith Concrete Mixers

SMALL TOOL AND SUPPLY DEPARTMENT
- Pratt and Whitney Tools
- Brown and Sharpe Tools
- Yale and Towne Hoists
- Alundum Grinding Wheels
- Crystolon Grinding Wheels
- India Oil Stone
- Parker Vices
- Union Chucks

SAFE AND TYPEWRITER DEPARTMENT
- Dominion Safes and Vaults
- Noiseless Typewriters

TRUCK DEPARTMENT
- Mack Trucks (gasoline)

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

(Continued from Page 75.)

"2. That the Applicant Company be, and it is hereby, authorized to slope the side of its cutting back on to the lands of the Grand Trunk Railway Company, shown colored red on the said plan, and then replace the fence on its former location along the property line; and that the slope be carried back on an incline of only 1½ to 1 according to the standard cross sections of cuttings for the Applicant Company's railway and for a depth of cutting shown on the profile on file with the Board under file No. 3701.298."

20082—August 16—Authorizing the C.P.R. to construct Bridges Nos. 86.45 and 50.95 on its line of railway.

20083—August 18—Authorizing the C.P.R. to operate its trains over the Lachine Canal drawbridge, near Highlands, without their first being brought to a stop.

20084—August 18—Authorizing the C.P.R. to construct Bridges Nos. 15.83, 12.65, 120.79, 9.17, 20.42, 39.11, 37.00 and 19.17 on its line of railway.

20085—August 14—Authorizing the C.P.R. to divert Pincher Creek Trail and to close that portion of the said Trail so diverted within the limits of its right of way; and construct a road diversion in Sec. 3, Tp. 7, Rge. 29, W. 4 M., Alta., in lieu of the said portion to be closed.

20086—August 15—Amending Order No. 19900 by striking out the figures and letters "19th" where they occur in the recital and operative parts of said Order, and substituting therefor the figures and letters "10th."

20087—August 15—Authorizing the C.P.R. and G.T.R. to operate their trains over the crossing of their tracks one mile north of St. Johns, Que., at mileage 20.85, without their first being brought to a stop.

20088—August 15—Authorizing the C.P.R. and the St. Lawrence and Adirondack Ry. to operate their trains over the crossing at Adirondack Jct., without their first being brought to a stop.

20089—August 19—Authorizing the C.P.R. to construct, maintain and operate a branch line of railway or spur for the Dominion Brick Co., Montreal, from a point on the southeasterly limit of the right of way of the C.P.R.'s St. Lin. Sub-division, in Lot 523, P.Q., to and into the premises of the Dominion Brick Co., situate in said Lot 523.

20090—August 19—Authorizing the C.P.R. to construct the tracks of extension of meeting siding at Islington Jct., C.P.R.'s main line, Ont., Sub-division, across Mimico Ave., at grade, between Lots 6 and 14, Con. 5, Tp. Etobicoke, Co. York, Ont.

20091—August 19—Authorizing the C.P.R. to construct road diversion in Lot 9002, Twp. 23, Rge. 18, W. 5 M., B.C.

20092——August 19—Authorizing the C.P.R. to reconstruct Bridge No. 113.1, on its Sherbrooke Sub-division, Eastern Div., P.Q.

20093—August 15—Approving revision in the location of a portion of C.P.R.'s main line as constructed of an additional track (double track) on the said revision, from a point in Lot 10, Con. 3, Twp. Balfour, thence in a westerly direction through Twps. Balfour, Dowling and Cascades to a point in Lot 1, Con. 1, Twp. Cartier.

20094—August 19—Authorizing the C.P.R. to construct Bridges Nos. 114.01, 128.79, 5.5 on its line of railway.

20095—August 18—Amending Order No. 19852 by inserting after the figure "13," in both the preamble and the operative part of the said Order, the word and figure "Township 13," so as to make the same read, "Sections 12 and 13, Township 13, Range 15, west of the 4th Meridian."

20096—August 16—Authorizing the the Cambellford, Lake Ontario and Western Ry. to construct an overhead farm crossing on the farm of Mrs. M. J. West at a point opposite the building, about eighteen rods from the east boundary of her farm, where there is a twenty-foot cut on the railway.

20097—August 18—Dismissing complaint of the business men and residents of East Calgary, Alta., complaining against the removal of the C.P.R. Co.'s station known as Maharg Stn., formerly Calgary Junction, at East Calgary.

20098—August 16—Ordering the C.L.O. and W. Ry. Co. to provide and construct a suitable cattle pass under its railway, where the same crosses the property of Fred S. Farrott, on Lot 12, Con. 1, Tp. Thurlow, Ont.

20099—August 16—Authorizing the C.P.R. to construct its tracks across the highway, at grade, in Lot 2566, Kootenay District, B.C., at mileage 41.27 from Golden.

20100—August 18—Authorizing the C.P.R. to construct road diversion in Sec. 19, Tp. 22, Rge. 23, and Sec. 13, Tp. 22, Rge. 24, W. 4 M., from mileage 5.23 to mileage 5.69 on its Gleichen-Shepard Branch.

20101—August 18—Authorizing the C.P.R. to construct the tracks of its Bromhead Ballast Pit Spur, at grade, across the roadway in Sec. 6, Tp. 3, Rge. 13, W. 2 M., Sask., at mileage 2 of said spur.

20102—August 18—Authorizing the C.P.R. to construct a diversion of the road allowance in Sec. 9, Tp. 13, Rge. 15, W. 4 M., Alta.; and to construct its tracks, by means of a grade crossing, across the said diversion, at mileage 45 of its Sheffield-Blackie Branch.

20103—August 14—Ordering the C.P.R. to provide and construct a farm crossing near J. M. Carroll's farm buildings in Beaver, B.C. at Station 3350-76.5.

20104—August 18—Approving location of a portion of C.P.R.'s Bassano Easterly Branch from a point in Sec. 15, Tp. 23, Rge. 1, W. 5 M., at mileage 116.00, thence in an easterly direction to a point in Sec. 13, Tp. 23, Rge. 1, W. 4 M., at mileage 118.39; and also approving revision in location of a portion of said branch line from a point in Sec. 10, Tp. 2, Rge. 1, W. 4 M., at mileage 115.59, thence in an easterly direction to a point in Sec. 15, Tp. 23, Rge. 1, W. 4 M., at mileage 116.00.

20105—August 18—Approving revised location of G.T.P. main line, mileage 321.6 to mileage 330.1, Prince Rupert East, through Tibbets Indian Reserve, Rge. 5, Coast District, B.C.

20106—August 15—Dismissing application of the Empire Flour Mills, Ltd., St. Thomas, Ont., for an order restoring the milling-in-transit arrangement on U.S. corn, the product of which is shipped from St. Thomas to points on or via the G.T. and the C.P. Railways.

20107—August 15—Authorizing the Niagara, St. Catharines and Toronto Ry. to construct, at its own expense, its lines and tracks across the lines and tracks of the Michigan Central Railroad Co.'s siding to the factory of the Dominion Canners, in the town of Niagara-on-the-Lake, Ont.

20108—August 16—Authorizing the C.N.O.R. to construct its line of railway across Wimma St., in O'Connor Park, town of Sudbury, Ont.

20109—August 15—Ordering the C.N.R. to remove Peace Avenue Siding, situate at the corner of Twenty-fifth St., Edmonton, on or before the 1st Sept., 1913.

20110—August 18—Authorizing the C.N.O.R. to take the portion of the east part of Lot 10, Con. 6, Tp. Nepean, the property of David Finlay.

20111—August 13—Authorizing the C.N.O.R. to construct its line of railway across Dell St. in O'Connor Park in the town of Sudbury, Ont.

20112—August 16—Authorizing the C.N.O.R. to construct bridge to carry its line of railway across the Indian River, at mileage 106.4 from Ottawa, Tp. of Fraser, Co. Renfrew, Ont.

20113—August 16—Authorizing the C.N.O.R. to construct bridges at mileage 188.1 from Toronto and mileage 98.06 from Ottawa, on its line of railway.

20114—August 19—Authorizing the C.N.O.R. to construct bridge to carry its line of railway over the Indian River, Tp. of Stafford, District of Nipissing, Ont., at mileage 88.2 from Ottawa.

20115—August 15—Authorizing the C.N.R. to construct highway crossing on its railway in the S.E. ¼ of Sec. 25, Tp. 12, Rge. 25, W. 2nd M., west of the station grounds at Bayard Townsite, Sask.

20116—August 19—Approving location of the C.N.R.'s station grounds at MacRorie, Sask.

When designing

structures do you pay sufficient attention to the various matters that govern insurance ratings?

Not only can you add greatly to the fireproofness of buildings by adopting our suggestions, but it is very likely that you can do so without the improvements costing anything ultimately. They will be paid for by the lower insurance rates.

Correspondence solicited. We have a staff of engineers and inspectors trained in this highly specialized line. Make use of our services.

In making sewer pipe

many pieces come from the kilns with imperfections. They are rendered imperfect by having pieces broken out of the socket or spigot end, or having fire cracks at either end or extending partly through the body of the pipe. Or they may be imperfect in shape, out of round or not straight; not thoroughly vitrified or glazed; or with blisters or scales blown off the outside. Such pieces cannot be classed as strictly first-class pipe. When buying pipe from us one can rest assured that we will never deliver pipe with imperfections such as above unless "seconds" are particularly asked for by the purchaser.

"Stands the Test of Constant Use."

A Professor of Civil Engineering has written us concerning the second edition of the American Civil Engineers' Pocket Book, as follows:—

"It is our intention to require it of all Civil Engineers and then to use it as a text-book in nearly all courses, supplementary to our other books. We are pleased with the qualities of the book which stand the test of constant use."

TENDERS CALLED FOR

PLANS AND SPECIFICATIONS ON FILE.

The Canadian Engineer, 820 Union Bank Building, Winnipeg:—

ISSUE CLOSE

28-8—Supplying power house machinery, Neepawa, Man. 12-9

The Canadian Engineer, 62 Church Street, Toronto:—

28-8—Supplying power house machinery, Neepawa, Man. 12-9

The Canadian Engineer, 628 Transportation Building, Montreal:—

28-8—Supplying power house machinery, Neepawa, Man. 12-9

EXTENSION OF TIME.

TENDERS FOR MACHINERY.

TOWN OF NEEPAWA, MAN.

Sealed tenders will be received up to noon September 12th, 1913, for machinery for additions to the power plant at Neepawa, as follows:—

Specification Section No. 1— 2 72 ft. by 18 ft. boilers.

Specification Section No. 2—1 187½ h.p. engine.

Specification Section No. 3—1 150 K. V. A. generator exciter and switchboard.

Specification may be obtained by applying to W. E. Skinner, Limited, Consulting Engineers, 204 Sterling Bank Building, Winnipeg, or to the undersigned, or may be seen at the offices of *The Canadian Engineer*, 820 Union Bank Building, Winnipeg; 62 Church Street, Toronto, or 628 Transportation Building, Montreal.

J. W. BRADLEY,
Secretary-Treasurer, Neepawa, Man.

CAYUGA, ONT.

Sealed tenders will be received up to noon on the 16th day of September, 1913, by the undersigned at Cayuga, Ontario, for the construction of twenty-six and one-half miles of stone macadam road in the county of Haldimand.

The work will be let in three separate and distinct contracts, not necessarily to the same individual.

Tenderers are required to examine the localities of the work and are requested to be present at the opening of the tenders at 2 p.m., on Wednesday, the 17th day of September, 1913.

Plans and specifications may be seen at the office of the County Engineers, Messrs. Jackson and Kyd, Dunnville, or may be had from them on the payment of $10, which sum will be refunded on return of the documents.

Lowest or any tender not necessarily accepted.

T. A. SNIDER, K.C.,
County Clerk,
County of Haldimand,
Cayuga, Ont.

CITY OF REGINA, SASK.

Sealed tenders, registered and clearly marked on the outside of the envelope "Tender for Power-House Equipment," and addressed to the City Commissioners at Regina, Sask., will be received up till noon of October 1st, 1913, for the supply of:—

Coal bunkers, ash hoppers, coal and ash conveyers and crushers.

Price to be on equipment erected on foundation built by the City of Regina according to contractor's requirements.

A marked cheque for 5 per cent. of the amount of the bid, and made payable to the City Treasurer, City of Regina, must accompany each tender.

Specifications may be obtained from E. W. Bull, Superintendent of Light and Power, Regina, Sask.

The City Commissioners reserve the right to reject any or all tenders.

TRADE ENQUIRIES.

The following inquiries relating to Canadian trade has been received. The names of the firms making these inquiries, with their addresses, can be obtained upon application to "The Inquiries Branch, the Department of Trade and Commerce, Ottawa," or the Secretary of the Canadian Manufacturers' Association, Toronto, or the Secretary of the Board of Trade at Toronto, Brandon, Halifax, Montreal, St. John, Sherbrooke, Vancouver, Victoria, Winnipeg, Calgary, and Chambre de Commerce du District du Montreal:—830.—A large Rotterdam house, lumber importers, is prepared to receive quotations from Canadian shippers. 836.—A Sicilian firm is open to give its agency to a party already connected with hardware and painters' supplies wholesale. 842.—A Scottish manufacturing firm, who are patentees of lock-joint cast-iron piping for water and gas works, invites inquiries from Canadian engineers responsible for drafting projects for municipal and railway work. 846.—Glasgow metal firm wishes to appoint agent. Only one with connection among engineers and works will be considered. Salary and commission. Full particulars are requested. 857.—A Durban firm with connections in engineering trade throughout South Africa is prepared to consider any offer of machinery specialties. 859.—A Durban firm of merchants is prepared to purchase wire. Quotations requested. 863.—A firm in South Africa, now handling many shovels, is prepared to purchase direct. Quotations and catalogues requested. 870.—A Durban firm will purchase direct, pine shelving and other lumber. Correspondence requested with f.o.b. St. John or Montreal quotations, or if preferred c.i.f. Durban. 880.—A Durban firm of lumber dealers requests correspondence re lumber-pine and poplar shelving, ½ inc and 1 in., must be even widths, 12, 14, 16, 18 and 20 inches, no odd widths. Lengths, 12, 14 and 16 feet. 886.—A Durban firm will purchase Canadian made shovels. Would prefer to see samples. 892.—A London firm, who import railway ties, would be glad to receive offers from Canadian manufacturers of same. 893.—A Manchester firm makes inquiry for names of Canadian exporters of St. John's spruce lumber. 897.—A London correspondent is open to purchase supplies of old scrap galvanized iron wire, and would like to hear from Canadian firms in a position to ship large quantities.

NEW INCORPORATIONS.

Howick Station, Que.—Howick Paving Company, $10,000. J. H. Lefebvre, T. Vass, C. A. Vass, both of Casaville.

Toronto, Ont.—Canadian Mineral Development Company, $40,000. G. B. Balfour, J. Barker, K. C. Balfour. St. Petersburg Graphite Mining Company, $500,000. R. D. Moorhead, L. Macaulay, J. E. Anderson. The Tube and Pipe Bending Company of Ontario, $100,000. J. F. Edgar, J. E. Maybee, L. M. Lewis.

Montreal, Que.—Montreal Advertising Club Company, $10,000. E. M. McDougall, J. J. Creelman, G. S. Stairs. Como Lake Shore, Incorporee, $20,000. J. N. Legault, Vaudreil, H. L. O'Donnoghue, J. Brousseau. Mallinckrodt Chemical Works, $100,000. J. W. Blair, C. A. Hale, R. W. Gibb. Arcade Film Theatre, $25,000. R. Chenevert, F. Callaghan, M. J. McLaughlin.

MEXICAN EAGLE ASPHALT

TRADE MARK

Building an asphaltic macadam road, penetration method, with Mexican Eagle Asphalt, for the Montreal Harbor Commission

MEXICAN EAGLE ASPHALT is specially adapted to the Canadian climate for paving, as it is not susceptible to changes in temperature and will not mark in the hottest weather. Dow and Smith, chemical engineers, say; "This is a very high quality of asphalt."

EVERY BARREL of our asphalt is guaranteed to be uniform and according to analysis. This is the guarantee of our principals, the Mexican Eagle Oil Co., Limited, a company that has over twenty-five million dollars working capital.

Mexican Eagle Asphalt is superior in purity to Burmudez, Trinidad, Californian or any other paving asphalt on the market, and it is a favorite for its high cementing value and ductility.

We can supply different grades of Mexican Asphalt for asphalt fillers, road binders, roofing asphalts, wooden water pipe coatings, waterproofings, etc. Also Durazzo Sicilian Rock Mastic Asphalt for sidewalks.

For prices, analyses, samples, etc., please address

CANADA Portland CEMENT

SOME men ask for so many bags of "cement"—

Others, more careful, say they want "Portland Cement"—

But the man who does the best work insists upon getting "Canada" Portland Cement—

And he looks to see that every bag bears this label

To specify Canada Portland Cement, is to introduce an additional safety factor into your calculations. Architects, contractors and engineers know the value of "making assurance doubly sure."

MECHANICAL ENGINEER—Experienced Designer, Cost Estimator and Salesman, Works Supervision, all kinds of steam engines, boilers, hydraulic pumps, air machinery and mining plants, seeks position with Consulting Engineer, Contractor, Manufacturers or agency business. Highest references, some capital. Box 102, *The Canadian Engineer*, Toronto.

SUPERINTENDENT SEEKS re-appointment on heavy work, experienced in big plant, steam shovel work, rock, hardpan, concrete, etc. Highest references. Box 110, *The Canadian Engineer*, Toronto.

YOUNG CANADIAN ENGINEER.—Experience, paper mill, electric substation, hydraulic power plant, field and office, wishes to get in touch with a manufacturing concern requiring the services of a permanent resident engineer or plant chief; superior references. Address Box 112, *The Canadian Engineer*, Toronto.

YOUNG ELECTRICAL ENGINEER desires position either as consulting or plant engineer; first-class character and education; one who will take an interest and make good. Box 114, *The Canadian Engineer*, Toronto.

MECHANICAL ENGINEER resident in Toronto desires position; wide experience in manufacture and installation; would accept temporary post; references. Box 116, *The Canadian Engineer*, Toronto.

SUPERINTENDING ENGINEER of construction now free to accept appointment. Large experience on public works, with specialty in tunnelling. Unexceptional references. Nine years' U.S.A. experience. Address T. H. D., Bartram & Wadsworth, Bank of Toronto Building, Toronto.

EXPERIENCED MUNICIPAL ENGINEER and Land Surveyor desires position. Ten years' experience in municipal engineering, two years as superintendent of construction; also experience in construction of concrete bridges and buildings, railway and land surveys and drainage works. Toronto graduate; O.L.S. seven years, A.M. Can. Soc. C.E. five years. Engagement of three to six months' duration acceptable; at present in the West. Address Box 122, *The Canadian Engineer*, Toronto

MECHANICAL ENGINEER, experienced in the design and manufacture of the Zoelly type of steam turbine up to 1,200 H.P., desires a position as engineer in charge with a company contemplating the manufacture of a line of turbines. Versatile, original and practical. Box 124, *The Canadian Engineer*, Toronto.

Condensed Advts.

Advertisements under this heading three cents per word per insertion. Minimum charge fifty cents per insertion.

MANUFACTURER of well-known waterproofing is open to receive applications from responsible agents for the sale of his product in Montreal and vicinity. Address Box 118, *The Canadian Engineer*, 617 Transportation Buildings, Montreal.

UNITED STATES MANUFACTURERS of concrete mixers is anxious to make agency arrangement with energetic salesman for the territory in and around Toronto. Address Box 120, *The Canadian Engineer*, Toronto.

ENGINEERS' AND CONTRACTORS' Reinforced Concrete Screw Piles—important Canadian and American patents for license or sale, enquiries invited. Helical Reinforced Concrete Screw Syndicate, 40 Commercial Road, Portsmouth, England.

THE ARCH PRINCIPLE OF SHIP CONSTRUCTION.

It is a matter of considerable interest to shipowners to know that, although the arch principle of ship construction is of comparatively recent date, yet during this year alone three vessels of this type have been taken in hand at various shipyards. One was delivered to Canadian owners a few months ago; a second similar ship is under construction by the North of Ireland Shipbuilding Company at Londonderry, and the third for the Donald Steamship Company, of New York, is now receiving her finishing touches. This is striking evidence of the increasing popularity of the arch principle of ship construction, showing that shipowners do really appreciate the economy to be effected by using this type of ship. The principal advantages of building on the arch principle are, briefly, a large reduction in first cost, cargo holds free of pillars and other obstructions, and increased carrying capacity, combined with very low net tonnage. Other special points of a more technical nature might be noted, namely, increased strength, better stability, greater freeboard, an unusually high deck platform, and no so-called "wells," either forward or aft of the bridge amidships, for seas to fill.

SCHOOL FOR HEALTH OFFICERS.

Beginning this fall, Harvard University and the Massachusetts Institute of Technology are to maintain in co-operation a school for public health officers. The object of this school is to prepare men for public health work, especially, to fit them to occupy administrative and executive positions, such as health officers or members of boards of health, as well as secretaries, agents, and inspectors of health organizations.

It is recognized that the requirements for public health service are broad and complicated, and that the country needs leaders in every community, fitted to guide and instruct the people on all questions relating to the public health. To this end, the instruction of the new school will be on the broadest lines. It will be given by lectures, laboratory work, and other forms of instruction offered by both institutions, and also by special instructors from national, state, and local health agencies.

54-inch pipe distributed for sewers at Montreal, Canada.

MERIWETHER SYSTEM
CONTINUOUS RE-INFORCED
CONCRETE PIPE

PATENTED

LOCK JOINT PIPE COVERS NORTH AMERICA

Sewage flowing through Lock Joint Pipe reaches the Atlantic Ocean, Pacific Ocean, Gulf of Mexico, Hudson's Bay and the Great Lakes.

Lock Joint Pipe is in use for sewers and water conduits in the following States: Connecticut, Delaware, Florida, Georgia, Illinois, Indiana, Kansas, Kentucky, Maryland, Massachusetts, Michigan, Missouri, New Hampshire, New Jersey, New York, Ohio, Oregon, Pennsylvania, South Carolina, Texas, Virginia, Washington.

The following Provinces of Canada: Quebec, Ontario, Saskatchewan, Alberta and British Columbia.

And in the Island of Cuba.

The Lock Joint Pipe Company is the largest manufacturer of reinforced concrete pipe in the world.

LOCK JOINT PIPE CO.

165 BROADWAY - NEW YORK CITY

Write for new Illustrated Catalog

QUEBEC and ONTARIO—Francis Hankin & Co., 202 Coristine Bldg., Montreal; 117 Mail Bldg., Toronto.
MANITOBA, SASKATCHEWAN and ALBERTA—Canadian Lock Joint Pipe Co., Ltd., Regina, Sask.
BRITISH COLUMBIA—Pacific Lock Joint Pipe Co., 1005 A St., Tacoma, Wash.; Globe Bldg., Seattle, Wash.

MARKET CONDITIONS

Montreal, August 30th, 1913.

Bar Iron and Steel.—Trade is reported active. Bar iron, $2.10 per 100 pounds; best refined horseshoe, $2.35; forged iron, $2.25; mild steel, $2.20; sleigh shoe steel, $2.20 for 1 x ⅜ base; tire steel, $2.30 for 1 x ¾ base; toe caulk steel, $3; machine steel, iron finish, $2.25.

Cement.—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1.40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re-purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain.—The market is quoted per 100 lbs. as follows:—¼-in., $5.65; 5/16-in., $4.70; ⅜-in., $4.00; 7/16-in., $3.65; ½-in., $3.45; 9/16-in., $3.45; ⅝-in., $3.35; ¾-in., $3.25; ⅞-in., $3.15; 1-in., $3.05.

Explosives and Accessories.—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron.—The market is steady. Prices, basis, 28-gauge, are:—Queen's Head, $4.40; Colborne Crown, $4.20; Apollo, 10¾ oz., $4.30. Add 25c. per 100 lbs. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe.—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $22.50 per ton; selected Summerlee, $22; soft Summerlee, $21.50 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron, number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19.25 to $19.50 per ton, on track.

Lath.—See Lumber, etc

Lumber, Etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph Poles: seven-inch top, cedar poles, 25-ft. poles, $2 each; 30-ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce, 4-ft x 1½-in., mill run, $3 to $3.25; pine, 4-ft. x 1½-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2.10; XX, $2.40; XXX, $2.80.

Pipe.—Cast Iron.—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe.—Wrought and Galvanized.—Demand is fair and the market steady: —¼-inch $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ⅜-inch, $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent off for black, and 59 per cent. off for galvanized. The discount on the following is 72½ per cent. off for black, and 62½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 72½ per cent. for black and 62½ per cent. for galvanized:—2-inch, $36; 2½-inch, $57.50, and 3-inch $75.50; 72½ per cent. off for black, and 62½ per cent. of for galvanized; 3½-inch, $95; 4-inch, $1 08.

Toronto, Sept. 3rd 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron.—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel.—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates.—¼-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes.—Orders continue active. Lap-welded, steel, 1¼-inch, 10c.; 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks.—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $13 to $15 per M., three grades.

Broken Stone.—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto, 60 cents.

Cement.—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot.—The market is lower at 15¾ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps.—75c. and $1 per 100; case lots, 5,0000, 20 per cent. off.

Dynamite.—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¾ cents pound, 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1¼c. per hundred. For 10-case lots and over deduct ¼ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1¼ cent.

Fuses.—Electric Blasting.—Double strength, $3.50 per hundred, advance 54c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 54c. per hundred for each 2-in. wire additional.

Iron Chain.—¼-inch, $5.75; 5-16-in, $5.15; ⅜-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3.55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe.—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40.60; 6-inch, $52.64. Galvanied Pipe, ¼-inch, $2.86; ⅜-inch, $2.86 ½-inch, $5.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead.—Firmer, $5.25 to $5.50.

Pig Iron.—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar.—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate.—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green, $8, with a prospect of advance. Dealers are fairly busy.

Sand.—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe.—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0.25	$0.40	$0.65	$1.00	$ 3.85
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00
Double junctions	1.85	2.00	3.85	5.00	16.25
Increasers and reducers	....	1.60	2.60	4.00	25.00
P. & H. H. traps	2.00	3.20	6.50	15.00	.....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes, 9 inches and under or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels.—Active.—We quote:—$2.65 to $3 cnt to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2.75 to $3 per 100 pounds. Extra for smaller sizes of angles and tees.

Sheet Copper.—22c. per lb.

Sheet Steel.—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized.—Apollo Brand.—Sheets, 6 or 8 feet long, 30 or 36 inches wide; 10-gauge, $3.00; 12-14-gauge, $3.00; 16, 18, 20, $3.30; 22-24, $3.40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 pounds. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin.—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel.—Jowett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates.—3-16-inch, $2.40 per 100 lbs.

Zinc.—Spelter.—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, Sept. 2nd, 1913.

Anvils.—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¼ to 10¾c.; anvil and vise combined, each $5.50.

Bar Iron.—$2.50 base.

Bars.—Crow, $4.50 per 100 pounds.

Beams and Channels.—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick.—Kiln run per M, $13; sewer per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland.—$2.40 to $2.50 per barrel.

Chain.—Coil, 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7-16, $4.75; ½, $4.50; 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5¾c. Tie out, 70 and 10 per cent.

Copper.—Tinned, boiler, 26½c., planished 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent discount.

Dynamite.—$11 to $13 per case.

Galvanized Iron.—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20, $4; 18, $3.95; 16, $3.90; Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30; 22, $4.30; 20, $4.10 per cwt.

Iron.—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26-gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American, $5.15; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe.—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7.80; 1½-inch, $9.35; 2-inch, $12.50; galvanized—½-inch, $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch.—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled.—3-16-in., $3.35 base; machinery, $3 base; shars, $4.50 base; share crucible, $5.50, cast share steel, $7.50; toe calk, $4.50 base; tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel.—8½ to 15c. per pound

A weekly paper for engineers and engineering-contractors

THE DEVELOPMENT OF SEWAGE DISPOSAL PRACTICE

HISTORICAL REVIEW OF THE SCIENTIFIC DISPOSAL OF WASTE — VARIOUS AGENCIES IN USE — PAPER READ BEFORE THE ONTARIO MUNICIPAL ASSOCIATION, TORONTO, AUGUST, 29TH

By E. SHERMAN CHASE,

Sewage Experiment Station, New York City.

IT is a fundamental biological law that no living organism can long exist in the midst of its own wastes. This law is as applicable to the municipal organism as to the individual. Methods for the disposal of human wastes are as old as mankind itself, but the problem of sewage disposal which confronts us today originated only sixty or seventy years ago. Before this time the disposal of waste was largely an individual duty and not until the adoption of the water-carriage system did it become a civic responsibility. At the beginning of the water-carriage system, the method of disposal was by discharging the contents of the sewers into the nearest watercourse. This same method is too frequently used to this day. As long as the volume of water receiving the sewage was large compared with the amount of sewage no great attention was paid to the desirability or otherwise of this means of disposal. Before the germ theory of disease, and even much later, the discharge of sewage in bodies of water used for water supply has been tolerated and the use of unpurified water from such sources has caused enormous loss of life from typhoid. With rapid growth of population the waters receiving sewage have become not only unsafe for water supply but have become, in many cases, so grossly polluted as to be unfit for boating, bathing or fishing. Many otherwise attractive streams and lakes have become open sewers, offensive both to sight and smell. In other cases, as with certain sea coast towns, extensive shell-fish industries have been threatened by the pollution of harbor water.

In Europe the problem became acute much earlier than in America, on account of the smallness of the streams and the density of population. Local nuisances, due to fouling of the streams, became so pronounced that means had to be taken very soon after the introduction of the water-carriage system to prevent further fouling of the streams receiving sewage. The condition of the Thames at London became so intolerable that a government commission was appointed in 1868 to investigate methods of sewage disposal with the end in view of restoring the river in England to some degree of its former purity. This commission, called the Rivers Pollution Commission, after investigation, reported that the best means of disposal was land irrigation, and for many years this opinion was of powerful effect in shaping sewage projects in Europe, and in England land irrigation had official sanction almost exclusively until 1908.

In America the problem was first attacked in Massachusetts, and the Massachusetts Board of Health started experiments in 1888 on the purification of water and sewage which are being continued to the present day. In respect to sewage the immediate result of their first experiment was the adoption in Massachusetts of sand or gravel beds for sewage treatment. The most important results, however, were the establishment of the scientific basis upon which sewage purification depends and the stimulation given to other investigations of the sewage question.

The Massachusetts experiments proved that sewage purification is largely a matter of oxidation through bacterial agencies. Bacteria and other micro-organisms in soil, water or artificial devices, if given an abundance of oxygen, oxidize complex, putrescible, organic compounds to simple, non-putrescible, inorganic substances. As long as oxygen is present the organic compounds in sewage give comparatively little offence, but as soon as this oxygen is exhausted the unoxidized organic matters decompose, giving rise to foul, ill-smelling compounds and gases. From this it will be seen that the whole problem in a nutshell is to supply sufficient oxygen to the sewage. In fact, the sewers of a city may be likened to the veins of a human body, the sewage to the impure blood in the veins and the means of purification to the lungs where the impurities are oxidized by the inhaled air.

Sewage Defined and Classified.—Sewage itself has been defined as the water supply of a city after use. It contains the wastes of man and of man's activities. In composition it is mainly water and the proportion of solid matter to water is about 1 to 999. Aside from the solid matter it carries innumerable forms of microscopic life, and often contains bacteria dangerous to health. The solid matter and the harmful bacteria bring about the sewage problem, the solid matter by offensive decomposition and the bacteria by producing disease. The solid matter can be divided into two kinds, organic and inorganic; the organic solids being those subject to purification. For practical purposes, another classification is made of the solids into floating, suspended and dissolved

solids. Floating solids consist of garbage, rags, paper, sticks, etc. The suspended solids are smaller particles carried in suspension by the sewage; and the dissolved solids are those in solution. The suspended solids are divided into settling and non-settling solids, the settling solids being those which will settle out when subjected to quiescent sedimentation, and the non-settling those which will not. The aim of proper sewage disposal is to prevent nuisances from the decomposition of these solids and to also prevent injurious effects to health from the disease bacteria.

Natural Purification of Sewage.—When sewage is discharged into a body of water, the forces of nature immediately begin its purification; bacteria and oxygen oxidise its organic constituents adverse conditions of temperature and food supply destroy large numbers of harmful bacteria and thus, under some conditions, disposal by dilution is both practical and scientific. It is estimated by various authorities that the amount of water in a stream receiving sewage must flow at a rate of 3 to 6 cu. ft. per second for each inhabitant contributing to the sewers. In lakes, the extent to which disposal by dilution can be used, depends entirely upon local circumstances, in respect to location of outlets, currents, location of water supply inlets, etc. Where disposal by dilution can be used it is important to prevent deposits of solids and to keep the oxygen content of the diluting water from becoming exhausted.

Screens to Collect Floating and Suspended Solids.—Under some conditions, where disposal by dilution can be practised, it is necessary to remove the floating solids. In this case screening is usually resorted to. Screening is also used previous to further treatment to protect pumps and prevent scum-forming materials from entering tanks. There are many types of screens, the most common, probably, is the bar screen. This screen consists of iron bars, spaced at regular intervals and inclined vertically to the sewage flow. The spacing of the bars varies from one-half to several inches. Sometimes two or more sets of screens are used, the spacing of the bars in the second set being less than that in the first. The material collecting on the bars is removed and destroyed. Of late years, especially in Europe, mechanical screens of fine mesh have been used and with more or less satisfactory results. Fine mesh screens not only remove the floating matter but also a portion of the more finely divided suspended solids, and in some cases they have been used in place of sedimentation tanks.

In America the best known mechanical screen is a cylindrical framework of steel, about 6 feet in diameter and 12 feet long, upon which wire-cloth of 40 meshes to the linear inch is fastened in removable segments. The wire-cloth is protected by a copper screen of larger mesh and heavier wire. This screen is revolved slowly and the wire-cloth is washed by the jets of water. The sewage enters at one end of the cylinder and, passing through the cloth, leaves behind the floating and some of the suspended solids. The screenings are carried by a worm to the outlet end of the screen where they can be collected and disposed of. For burning, the screenings can be dried in a centrifugal dryer and mixed with coal. This type of screen removes 15 to 20% of the undissolved solids contained in a sewage. It is a somewhat expensive operation and is unnecessary where tanks are used.

Settling Tanks.—Tanks with and without the aid of chemicals have been used for many years for the settling out of sewage solids. Plain settling tanks are those receiving sewage untreated by chemicals and from which the deposited solids or sludge are removed before very much decomposition has taken place. Usually they are built rectangular in plan with sloping floors for sludge drainage. In the design of sewers, it is the aim of the engineer to keep the cross-section small enough to prevent low velocities of flow, thereby preventing deposition; on the other hand, in the design of settling tanks it is essential to obtain as low a velocity as possible in order to increase the amount of sedimentation. The length of time that sewage stays in a tank is much less important than the velocity with which it flows through, provided the period of retention is not so great as to cause undesirable decomposition. A very efficient type of tank is that designed by Mr. Watson for Birmingham, England. This is a cylindrical tank with a conical bottom, the sewage enters above the bottom at the centre of the tank and, flowing upward, slowly passes out through wires arranged around the top of the tank. The solids settle out into the conical part and can be removed by the hydraulic head without interrupting the operation of the tank.

Tanks for chemical precipitation are of various shapes but are most frequently rectangular in plan and the addition of chemicals take place just before the sewage enters the tank. The chemicals commonly used are lime and copperas; these, when mixed, form a flaky precipitate which carries down the particles of suspended solids. In some cities where trade wastes from iron manufacture enter the sewage the amount of iron in the sewage is sufficient to give a good precipitate when lime alone is added. The tanks can be cleaned by draining off the supernatent tanks to the level of the sludge and the sludge removed by sludge pumps. The sludge in chemical precipitation tanks is very heavy and rather difficult to handle. Chemical precipitation has the advantage over plain sedimentation that it removes some of the non-settling solids as well as the settling. It is, however, more expensive.

The Function of the Septic Tank.—The so-called septic tank is an attempt to utilize the decomposing action of bacteria in reducing the amount of organic solids to be dealt with. The septic tank is similar in design to the plain settling tank, but it is operated with very infrequent removal of the sludge. The period of retention of the sewage in the septic tank is usually much longer than in the settling tank. After the sewage has been retained a short time the oxygen originally present is exhausted and the putrefactive bacteria which work best in the absence of oxygen, begin to break down the organic matter. The organic solids are decomposed into liquids and gases thereby becoming somewhat less in quantity. At one time it was thought that this action would prevent the forming of any sludge, but while there is some reduction in the quantity of sludge, it is much less than was formerly thought. Besides, when a tank of sewage is undergoing rapid decomposition bubbles of gas bring quantities of sludge to the surface, often forming a scum on the top of the tank as well as on the bottom. The effluents from septic tanks are often more offensive than those from plain settling tanks, due to products of putrefaction.

Within the past few years a two-story tank has been derived which attempts to combine the advantages of plain sedimentation of the settling solids with the sludge digestion by the septic process. Tanks of this type have been devised by Mr. Imhoff, of Essen, Germany, and are known as Imhoff tanks. These tanks are coming into general use both in America and abroad. The Imhoff

tank is divided into two stories by a false bottom; the upper part serving as the sedimentation chamber and the lower part for the storage and digestion of the sludge. The false bottom is arranged into slits in such a way as to allow the settled solids to pass into the digestion chamber and yet not allow the gases or sludge to pass through into the sedimentation chamber. By this means the liquid passing through the tank remains practically unchanged by any septic action which takes place in the deposited solids. This type of tank is usually twenty to thirty feet deep and the decomposition of solids under head produces a sludge full of gas bubbles under pressure. When the sludge is withdrawn the gas expands and the resulting sludge is very porous and easily drained and dried.

Another development in tank treatment is the tank originated by Dr. Trans at Hampton, England. This tank not only removes settling solids, but a portion of the finely divided non-settling solids. This is accomplished by hanging plates in the sewage flow and on these surfaces aggregate the small particles of solids until a settling mass is formed which sinks into the sludge tanks. Like the Imhoff tank, the Trans tank has a separate compartment for sludge digestion, but unlike it, allows a portion of the flow to pass through this digestion chamber.

The Disposal of Sludge.—Whatever method of tank treatment is used, some means must be found to dispose of the sludge produced. Even the best sludge contains considerable amounts of putrescible organic matter and this organic matter, together with the high per cent. of water, renders the sludge problem somewhat difficult to solve. Part of the sludge treatment really takes place in the tanks due to the action of the bacteria in breaking down the organic compounds, but the removal of the water or drying of the sludge must take place outside. The sludge from deep tanks, where the sludge is drawn off under pressure, contains less water than that from shallow tanks, or that from tanks which have the supernatent water removed before cleaning. The best sludge will run as low as 75% moisture, but even then it is too wet to handle easily. Methods used for sludge drying are filter pressing, draining on sand beds and drying in centrifugal machines. Strictly speaking, these methods do not finally dispose of the sludge, but the dried sludge can be used for filling in low land or for fertilizer. Without drying, sludge can be disposed of by trenching the land and filling the trenches with wet sludge and eventually plowing the sludge underneath the soil. At Columbus, Ohio, the sludge is run into the river during the winter when the flow is sufficient to dilute the sludge without nuisance.

Although there are undoubtedly valuable fertilizer constituents in sewage sludge, the great difficulty in realizing this value is due to the high per cent. of water in even the dried material. To have value as a fertilizer it must not contain over 15% of water, and about the best that sludge-drying methods to date have been able to accomplish is 50% moisture. Probably the next few years will show developments in successful sludge utilization.

For the removal of dissolved organic solids, the earliest method is that of land irrigation. This method simply controls the flow of sewage over an area of land, this land being utilized for farming. Land irrigation given satisfactory effluents requires large areas of land, gives rise to nuisance from odors and flies, and on the whole is more costly than the modern methods. The sewage farms in Berlin cover about 43,000 acres, and those which are being abandoned gradually in Birmingham, England, 28,000. The financial aid realized from the sale of crops is not as great as might be expected and this method is generally going out of use.

A step in advance is the intermittent sand filter, as developed by the Massachusetts Board of Health. This filter consists essentially of a graded bed of sand or gravel, four or five feet in depth, well underdrained by lines of tile laid with open joints. Sewage applied evenly to the surface at regular intervals percolates through the bed and runs off in the drains. Bacteria and other microorganisms form a jelly-like covering on the surfaces of the sand grains and in conjunction with the air present oxidize the impurities. It is necessary to operate this type of filter intermittently in order to admit the air required for oxidation. Although excellent results are obtained with intermittent filtration, the same objection holds as with land irrigation. For large plants this type is very seldom adopted now-a-days, although for small quantities and where high degree of purification is required, it is extremely useful.

The Contact Bed and Sprinkling Filter.—The experiments of the Massachusetts Board of Health with sewage filtration through coarse gravel, led to further investigation on a practical scale in England and two forms of filters of coarse material were developed, the contact bed and the sprinkling filter.

The contact bed consists of a tank filled with broken stone to a depth of 4 or 5 feet, the bottom being underdrained and devices for the control of the sewage flow provided. The method of operation is to fill the bed with sewage, allow it to stand full for a short period, then drain until empty; this process being constantly repeated. While standing full some of the solid matter is deposited upon the surfaces of the stone, and while draining the air admitted, aided by the bacterial films developed on the stone, oxidizes the organic matter. It is necessary to pass the sewage through two or more beds of this type successively to get a well-oxidized and stable affluent. The use of coarse material allows much larger quantities to be treated than with sand filtration, although in time the voids become filled with solids and the material has to be renewed. The affluent from contact beds is usually non-putrescible and inoffensive, but is not as good as that from a sand filter. Contact beds, however, can be operated at a rate of 500,000 gallons per acre per day, while the best a sand bed can do is 100,000 gallons. The cost of operation is also much less

A sprinkling filter is essentially a bed of broken stone 5 to 8 feet in depth, placed over a concrete floor. The floor is covered with an under-drainage system for the rapid removal of the affluents and for ventilation. The sewage is applied to the surface of the filter in the form of a fine spray through a series of sprinkler nozzles, spaced symmetrically over the bed, these nozzles being fed by a system of distribution pipes connected with some sort of dosing apparatus. In passing through the air the sewage absorbs oxygen, and as in the other methods described, the bacteria growing on the filter stones, use their oxygen to oxidize the organic matter. On account of the continuous application of sewage and the constant supply of oxygen, the rate of filtration with a sprinkling filter is very high, running from one to three million gallons per acre per day. Usually final settling basins are provided for after treatment with this type of filter.

These basins are needed to collect the solids which wash out from the filter at periodic intervals. Unlike the contact bed, the sprinkling filter does not require to have the filtering media renewed on account of the clogging because at certain times of the year the clogging solids are washed out naturally and the media becomes absolutely clear. If fresh sewage is applied to sprinkling filter very little nuisance arises from odor; with both sprinkling filter and contact bed previous tank treatment is usually adopted, the best type of tank being that which delivers the freshest sewage with the largest amount of settling solids removed.

None of the processes of sewage purification destroy completely the bacteria present in the sewage. Well-operated land irrigation areas and intermittent filters give the best grade of effluent but, as we have stated, are being largely superseded to-day by the more rapid methods. Under some circumstances it is desirable to obtain an effluent reasonably free from possible disease germs. In this case practical sterilization can be accomplished by the use of chemicals; hydrochlorite of lime or bleaching powder being most commonly used. This chemical, when dissolved in water, liberates active oxygen which is extremely efficient as a germicide. About 99% of the bacteria in sewage effluents can be killed by adding 75 pounds of strong bleacher per million gallons. Raw sewage can also be largely freed from bacteria by larger quantities of the bleach. Other methods have been proposed by sterilization, such as the use of ozone and of chlorine gas. The use of the former in sewage work is probably prohibited on account of its cost. There seems to be a good field for chlorine gas and several types of machines are devised for using liquid chlorine from cylinders.

STEEL WHEELS FOR MOTOR TRUCKS.

One of the most interesting developments in the steel casting business recently has been the increase in the use of steel wheels for motor trucks. Automobile engineers have turned their attention to steel because the high quality of wood required for truck wheels is being rapidly exhausted. Also, wood wheels cause a good deal of trouble by variation of size, and cannot be used successfully in very dry climates.

While the cast-steel wheel overcomes all of the above objections, it has the disadvantage of excessive weight, the development of cracks, and it is not as resilient as wood. The proper design of truck wheels of very thin section is helping to overcome this to a great extent, and a few steel casting concerns are building up a large business on cast-steel wheels.

The annual purchases of British electrical goods, exclusive of machinery, by Australia have risen within five years from £350,000 to £858,000; in the case of India, from £223,000 to £330,000; South Africa, from £99,000 to £307,000; New Zealand, £78,000 to £153,000; and Canada, £49,000 to £278,000; while the demand on behalf of countries outside the empire is hardly less remarkable, as exemplified by Japan, which last year purchased British electrical goods, exclusive of machinery, to £375,000, against £126,000 in 1908; Egypt, £395,000, compared with £23,000 in the former period; the Argentine, £268,000, contrasted with £148,000; and Brazil, £167,000, against £86,000. The United States last year bought British goods of this class to no less than £169,000, against only £9,000 five years ago.

TYPICAL SPECIFICATIONS FOR STEEL HIGHWAY BRIDGES.

THE Office of Public Roads of the United States Department of Agriculture has just issued a set of typical specifications for the fabrication and erection of steel bridges for highways. The bulletin, compiled under the direction of L. W. Page, is offered as a suitable guide for highway officials in fixing requirements to which bridge structure should be made to conform with a view to eliminating the prevalence of poorly constructed bridges, indicative of a lack of information on the part of highway officials concerning proper specifications for this class of work.

Two classes of bridges are considered under these specifications—those which carry suburban or interurban electric cars and those which carry highway traffic only. The former are designated as class A and the latter as class B bridges.

Types of Bridges.—It is recommended that the type of bridge employed be selected as follows:—

For spans up to 30 feet—rolled beams.

For spans from 30 to 40 feet—plate girders or rolled beams.

For spans from 40 to 80 feet—riveted low trusses or plate girders.

For spans from 80 to 200 feet—riveted high trusses.

For spans over 200 feet—pin-connected high trusses.

All parts of the superstructure except the floor shall be of rolled steel.

In computing the stresses the length of span for the trusses or girders shall be taken as the distance from centre to centre of the end bearings; and for the floor beams, from centre to centre of the trusses.

Width of Roadway.—For Class A bridges the clear distance between the centre line of the car tracks and the nearest truss shall be not less than 7 feet, and on one side the clear distance betwen the centre line of the car track and the truss shall be at least 12 feet. The width from centre to centre of trusses shall in no case be less than one-eighteenth of the span.

The clear head room for a width of 6 feet on each side of the centre line of the bridge shall be not less than 15 feet.

The ratio of depth of span shall be not less than the following: For rolled beams, 1/20; for plate girders, 1/12; for trusses, 1/10.

Loads.—The assumed dead load shall be not less than the total weight of the completed structure. The following unit weights shall be used in computing the dead loads:

Steel	490 pds. per cu. ft.
Concrete	150 " "
Brick	150 " "
Macadam	130 " "
Asphalt	135 " "
Sand or earth	100 " "
Stone	160 " "
Timber:	
Creosoted	5 pds. per ft. b.m.
Oak, untreated	4½ " "
Pine, untreated	4 " "

Class A.—For the floor and its supports and for the trusses of spans less than 50 feet in length the live load shall be assumed as follows:

On each car track a concentrated load of 24 tons evenly divided between two axles, spaced 10 feet centre to centre with wheels spaced 5 feet centre to centre on axles, shall be assumed to occupy a width of 6 feet on each side of the centre line; on the remaining floor surface, exclusive of sidewalks, a uniform load of 125 pounds per square foot and on sidewalks a uniform load of 100 pounds per square foot.

For the trusses of spans between 50 feet and 100 feet in length, a uniform load of 1,800 pounds per linear foot for each car track (assumed to occupy a width of 12 feet) and 100 pounds per square foot of remaining floor surface including sidewalks, shall be assumed. For the trusses of spans greater than 100 feet in length, the live load per linear foot for each car track and per square foot of remaining floor surface may be reduced, respectively, 50 pounds and 2 pounds for each additional 10 feet of span, provided that in no case shall these loads be reduced below 1,200 pounds and 80 pounds, respectively.

All class A bridges shall be assumed as also subject to the loading specified for class B bridges.

Class B.—For the floor and its supports and for the trusses of spans less than 50 feet in length, the live load shall be assumed as follows:

On any part of the floor surface a concentrated load of 15 tons on two axles spaced 8 feet centre to centre, with wheels spaced 6 feet centre to centre on axles two-thirds of the load on one axle, shall be assumed to occupy a space 16 feet in the direction of traffic by 12 feet at right angles to that direction. On the remaining floor surface, exclusive of sidewalks, a uniform load of 125 pounds per square foot and on sidewalks a uniform load of 100 pounds per square foot, shall be assumed.

For the trusses of spans between 50 feet and 100 feet in length a uniformly distributed load of 100 pounds per square foot of floor surface shall be assumed. For the trusses of spans greater than 100 feet in length the uniform load per square foot may be reduced 2 pounds for each additional 10 feet of span, provided that in no case shall the assumed live load be less than 80 pounds per square foot of floor surface.

Distribution of Stresses Due to Concentrated Loads.—In considering the concentrated load under Class A, each wheel load shall be assumed distributed over an area of floor surface 5 feet square. In considering the concentrated load under class B, each wheel load shall be assumed distributed as follows: For reinforced concrete floors, protected by a wearing surface, 3 feet in the direction of traffic by 5 feet at right angles to that direction; for wood floors at least 3 inches thick the distribution in the direction of traffic shall be neglected in designing the joists and the distribution at right angles to the direction of traffic shall be taken as 4 feet.

The top lateral bracing in deck bridges and the bottom lateral bracing in through bridges shall be designed to resist a lateral wind load of 300 pounds per linear foot, and one-half of this shall be treated as a moving load.

The bottom lateral bracing in deck bridges and the top lateral bracing in through bridges shall be designed to resist a lateral wind load of 150 pounds per linear foot.

Provision shall be made for stresses due to a change in temperature of 150°F.

For class A bridges provision shall be made for a longitudinal force equal to 20 per cent. of the weight of the heaviest electric train which could reasonably be expected to come upon the bridge.

Impact and Centrifugal Force.—The maximum live-load stress in each member shall be increased to provide for impact by an amount to be determined from the formula $I = \frac{100\ S}{L + 300}$, where

I = impact or dynamic increment due to the effect of moving loads;

S = computed live-load stress; and

L = loaded length of bridge in feet which produces maximum live-load stress in the member under consideration.

When curved tracks occur on class A bridges, the centrifugal force produced by two cars coupled together moving at 50 miles an hour shall be considered as an additional live load in designing the lateral bracing.

Proportions and Unit Stresses.—All members shall be so designed that the stresses coming upon them may be accurately computed, and shall be so proportioned that the sum of the maximum stresses produced by the loads herein specified shall not exceed the following amounts in pounds per square inch.

Axial tension on net section—16,000; axial compression on gross section—$16{,}000 - 70\frac{l}{r}$, where l is the length of the member in inches and r is the least radius of gyration of its cross section in inches.

For class A bridges no compression members shall have an unsupported length exceeding 100 times its least radius of gyration for main members, or 120 times its least radius of gyration for laterals. For class B bridges no compression member shall have an unsupported length exceeding 120 times its least radius of gyration for main members, or 140 times its least radius of gyration for laterals.

Bending stresses on extreme fibres of rolled floor beams, joists, and girders, 12,500; on extreme fibres of built-up girders, 16,000; and on extreme fibres of pins, 20,000.

Shearing—

Pins and shop-driven rivets	10,000
Field-driven rivets	7,500
Plate-girder webs (gross section)	9,000

Bearing—

Shop-driven rivets	20,000
Pins and field-driven rivets	15,000
Wall plates on concrete masonry (1 : 2½ : 5)	500
Wall plates on stone masonry (ashlar)	500
Wall plates on stone masonry (rubble)	400
Expansion rollers (per lineal inch)	500d

where d is the diameter of the roller in inches.

Alternate Stresses.—Members subject to alternate tensile and compressive stresses shall be proportioned to resist each kind of stress, and each stress shall be considered as increased by an amount equal to eight-tenths of the smaller stress in determining the sectional area. The connections shall be proportioned for the arithmetical sum of the stresses.

Combined Stresses.—Members subject to a combination of direct and bending stresses shall be designed so

that the greatest unit fibre stress shall not exceed the allowable unit stress for the timber.

Counters.—Wherever the live and dead load stresses are opposite in character, only two-thirds of the dead-load stress shall be considered effective in counteracting the live-load stress.

For class A bridges counters shall be so provided and proportioned that an increase of 25 per cent. in the specified live load would not increase the unit stress in any member more than 25 per cent.

Net Section at Rivets.—In proportioning tension members the diameter of the rivet holes shall be taken ⅛ inch larger than the nominal diameter of the rivets.

Proportioning Plate Girders.—The flanges of plate girders shall be assumed to take all the bending moment, and the web shall be assumed to take all the shear. The compression and tension flanges shall have the same gross section.

The Floor System.—All floor beams shall be rolled or riveted steel girders and shall be rigidly connected to the trusses or side girders. They shall, when practicable, be placed at right angles to the direction of traffic.

All joists shall be rolled or riveted steel girders and shall be rigidly fastened to the floor beams. When wood floors are used, the joists shall be riveted to the webs of floor beams by means of connection angles. The spacing of joists centre to centre shall be not greater than 3 feet.

Wood floors shall be constructed of first-quality timber of the kind specified by the engineer in writing or indicated on his drawings. For oak floors the minimum thickness of plank used shall be 2½ inches, and for pine the minimum thickness shall be 3 inches. In no case shall the thickness of the floor plank be less than one-twelfth of the distance, centre to centre, between joists. All plank shall be laid with the heart side down at right angles to the direction of traffic. Spaces approximately ¼ inch shall be left between adjacent planks.

Wood floors shall be provided with a wheel guard on each side of the roadway. Wheel guards shall be constructed of timbers having a cross section of not less than 6 inches by 4 inches, spliced with 6-inch lap joints, and shall be securely bolted to the joists at intervals not to exceed 5 feet.

Adequate provision shall be made for draining all parts of the floor, and the water drained off shall go clear of all metal work.

Details of Design and Construction.—The minimum thickness of metal used in any part of the structure, except that used for fillers and other minor parts, shall be 5/16 inch. For class B bridges, however, this specification may be modified by the engineer in writing to permit the use of standard channels and I-beams having web thicknesses of less than 5/16 inch, provided that the modification is made as a supplementary clause to these specifications before the contract is awarded or is indicated on the engineer's general drawings.

Truss spans shall be given a camber by making the horizontal projection of the top chord longer than the bottom chord by 3/16 inch for each 10 feet of span.

All connections shall be designed to develop the full strength of the connecting members and shall be of the character indicated on the engineer's drawings or by the engineer in writing.

Angles subject to tensile stress shall be connected by both legs, otherwise only the section of the leg actually connected will be considered effective.

The neutral axes of connecting members shall meet in a point.

Rivets and Rivet Spacing.—Rivets shall be either ⅞ inch, ¾ inch, or ⅝ inch in diameter, except when used in minor parts.

The maximum pitch in the line of stress shall not exceed 6 inches or 16 times the thickness of the thinnest outside plate. The minimum pitch shall not be less than 3 inches for ⅞-inch rivets, 2½ inches for ¾-inch rivets, and 2 inches for ⅝-inch rivets. For plate girders the rivet spacing in the vertical legs of the flange angles shall be determined from the formula, $p = \frac{rh}{s}$, where p is the pitch in inches, r the permissible stress in one rivet in pounds, h the distance between lines of rivets in inches, and s the maximum shear in pounds at the section under consideration. In no case, however, shall the pitch exceed 4 inches.

The minimum distances from centre or rivet holes to the nearest edge shall be not less than 1½ inches, 1¼ inches, and 1 inch for ⅞-inch rivets, ¾-inch rivets, and ⅝-inch rivets, respectively. The maximum distance from any edge to the centre of rivet holes shall not exceed 8 times the thickness of the thinnest outside plate or 6 inches.

Unless otherwise specified in the engineer's drawings or by the engineer in writing, ⅝-inch rivets shall be used for all flanges less than 2½ inches wide, ¾-inch rivets for flanges between 2½ and 3½ inches, and ⅞-inch rivets for all flanges over 3½ inches wide.

At the ends of built compression members the pitch of rivets in the line of stress shall not exceed 4 diameters for a distance equal to twice the maximum width of the member.

The grip of rivets shall, in general, be not greater than 4 diameters. When it is necessary to make the grip greater than 4 diameters, the allowable unit shearing strength shall be decreased 1 per cent. for each 1/16 inch of additional grip.

Pin Connections.—All pins shall be sufficiently long to furnish full bearing upon the turned body of the pin for all connecting parts. All pins shall be secured by chambered nuts and the screw ends shall be sufficiently long to admit of burring the threads after the nuts are set.

No pin shall have a diameter less than three-fourths the width of the widest eyebar attached to it.

The several members attaching to a pin shall be so placed as to produce as little bending movement as practicable upon the pin; and they shall be held in place by means of filling rings.

All pin holes shall be so bored that when the pin is in place it shall be perpendicular to the axial plane of the truss, and each connecting member shall bear uniformly upon the pin. The diameter of the hole shall not be more than 1/32 inch greater than that of the pin.

Pin holes shall be sufficiently reinforced to distribute the stresses properly over the full cross section of the members. Where "pin plates" are used, they shall contain a sufficient number of rivets to transmit their proportion of the bearing pressure, and at least one plate on

each side shall extend not less than 6 inches beyond the edge of the nearest batten plate.

Riveted tension members having pin connections shall have a cross sectional area through each pin hole 25 per cent. in excess of the net sectional area of the members. The sectional area of the metal between the pin hole and the end of the member shall not be less than 75 per cent. of the sectional area through the pin hole.

Batten Plates and Lattice Bars.—The open sides of compression members shall be stayed by batten plates at the ends and by diagonal lattice bars at intermediate points. Batten plates shall be used at intermediate points when, for any reason, the latticing is interrupted.

Batten plates shall have a thickness of not less than ¼-inch nor one forty-fifth the distance between the lines of rivets connecting them to the flanges. They shall have a width parallel to the axis of the member not less than the maximum width of the member.

Lattice bars shall have thickness not less than 5/16-inch nor less than one forty-fifth their unsupported length. They shall be inclined to the axis of the member at an angle not less than 60° for single latticing nor less than 45° for double latticing. Double latticing shall be riveted at the intersection points.

The width of lattice bars shall not be less than 2 inches nor less than on-sixth the width of the member of which they form a part.

Abutting ends in compression members shall be planed true to the angle of the joint and shall be sufficiently spliced on four sides to hold the connecting parts accurately in place. All joints in tension members shall be fully spliced.

Where splice plates are separated from the parts which they connect by intervening plates or fillers, the number of rivets on each side of the joint shall be increased by 33⅓ per cent. of the number theoretically required for each intervening plate.

The thickness of eyebars shall not be less than ⅝-inch nor less than one-seventh the width of the bar. Heads of eyebars shall be formed by upsetting and forging, and never by welding. The heads shall be so proportioned as to develop the full strength of the bar.

Eyebars shall be perfectly straight at the time they are bored, and all bars which work together as one member shall be piled, clamped together, and bored in one operation.

The eyebars composing a member shall be so arranged that their surfaces are not in contact. The inclination of individual eyebars to the axis of the member which they compose shall not be greater than 1 inch in 16 feet.

No rod shall be used which has a cross sectional area less than ¾ square inch.

All roads having screw ends shall be upset, previous to threading so that the net sectional area at the root of the threads shall be greater by at least 17 per cent. than the net sectional area of the rod.

Compression members shall be so designed that any part of segment of a member will be proportionately as strong as the member taken as a whole.

No web shall have a thickness less than one-thirtieth the distance between the lines of rivets connecting it to the flanges, and no cover plate shall have a thickness less than one-fortieth the distance between rivet lines.

Flanges of built members which have no cover plates shall have a thickness not less than one-twelfth the width of the outstanding leg.

Lateral System.—All lateral and portal bracing shall be made of shapes capable of resisting both compression and tension, and shall have riveted connections to the chords.

Laterals shall be as nearly in the plane of the axes of the chords as practicable. When eccentricity is unavoidable, however, provision shall be made for the maximum bending stresses which would be produced in the connections with the member fully loaded.

Portals for through bridges shall be as deep as the specified head room and depth of truss will permit. They shall consist of top and bottom struts and stiff intermediate bracing. All portals shall be provided with curved knee or corner braces.

Intermediate top struts in through bridges shall have a depth not less than that of the top chord, and, if the engineer so requires, they shall be provided with curved knee or corner braces.

End struts shall be provided at the ends of all bottom chords.

All deck bridges shall be provided at each panel point with sway bracing made of shapes capable of resisting both tension and compression. The sway bracing shall extend the full depth of the trusses, and at the end of the trusses ample provision shall be made for transferring all wind loads to the piers or abutments.

A substantial hand railing not less than 3½ feet high and of appropriate design shall be constructed on the outside of footwalks, or, when footwalks are omitted, at the outside of the roadway.

Expansion and Contraction.—Provision shall be made for all bridge structures to change in length owing to temperature changes at least ⅛-inch for each 10 feet of span, and joints shall be provided at such points in the floor and pavement as may be indicated on the drawings furnished or approved by the engineer.

For all beam and girder bridges expansion bearings shall be designed for motion to take place by sliding. For all truss bridges the expansion bearings shall preferably be provided with rollers or rockers, though for spans less than 80 feet in length the engineer may, in his discretion, permit the use of sliding bearings. All rollers or rockers shall have a diameter of at least 3 inches. In all cases the bearings shall be so designed that motion can take place in a longitudinal direction only, and shall be so placed at the time the bridge is erected that the shoe or bolster will occupy a central position on the bearing at the atmospheric temperatures specified by the engineer in writing.

Shoes or bolsters shall be so designed as to distribute the load over the entire bearing, and shall be securely stayed against lateral or upward motion by anchor bolts. Fixed bearings shall be rigidly anchored to the masonry.

Bedplates shall be designed to distribute the load over an area sufficiently great to keep the pressure upon the masonry within the hereinbefore specified limits. All bed and bearing plates on masonry shall be set on sheet lead not less than ¼-inch thick and the same size as the plate.

DESIGN FOR THE FOUNDATION OF 150-TON SHEAR-LEGS.

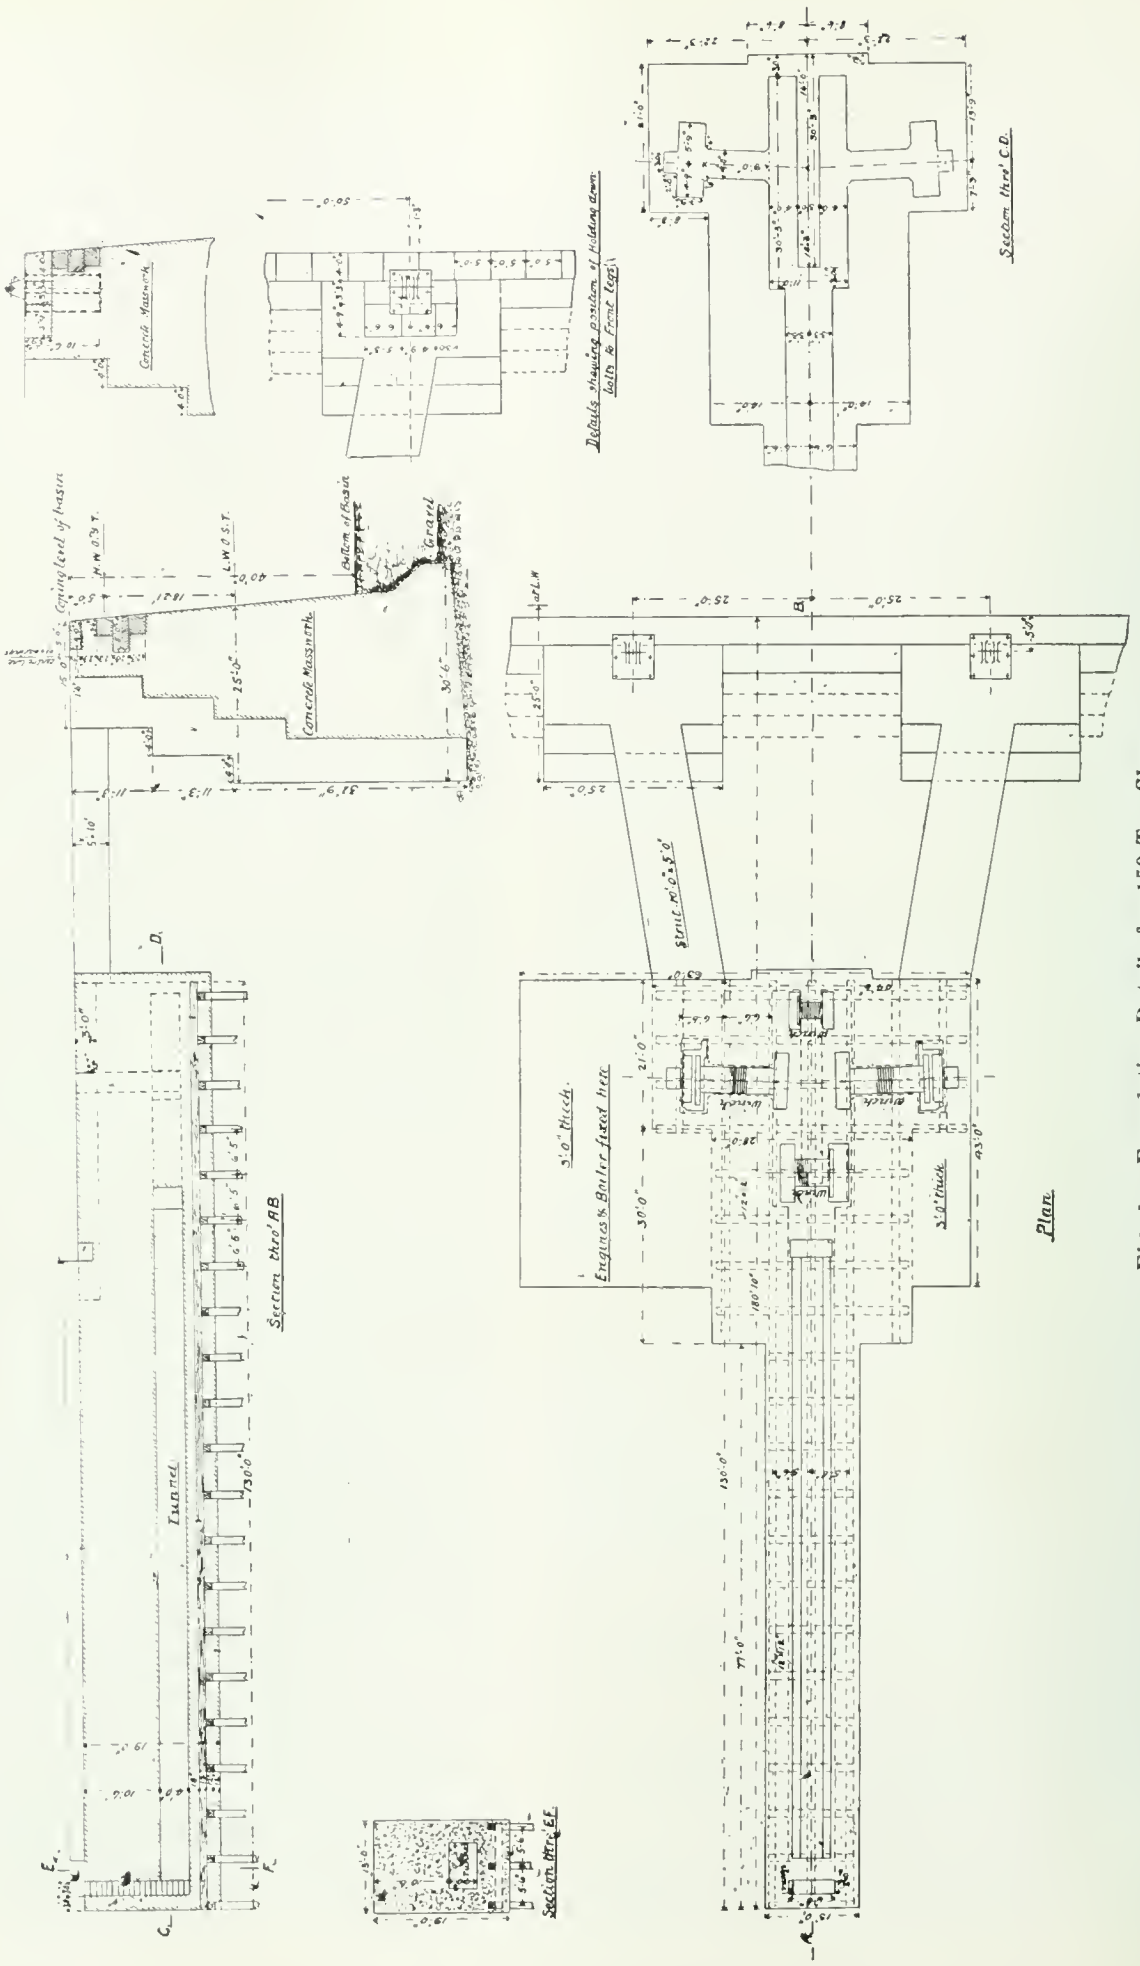

Fig. 1.—Foundation Details for 150-Ton Shears.

DESIGN FOR THE FOUNDATION OF 150-TON SHEAR-LEGS.

By Leonard Goodday, C.E., M.E.
Late of the British Admiralty.

A FEW years ago the writer was associated with the construction of some new docks and basin accommodation in England. The work included the design and erection of shear-legs for the support of hoisting tackle, a most essential factor in dock yards where heavy weights are to be hoisted over the side of a wharf or lowered to the deck of a vessel. Guns and heavy machinery are easily and comparatively quickly handled by this means, and this manner of hoist is also frequently used in "stepping" masts.

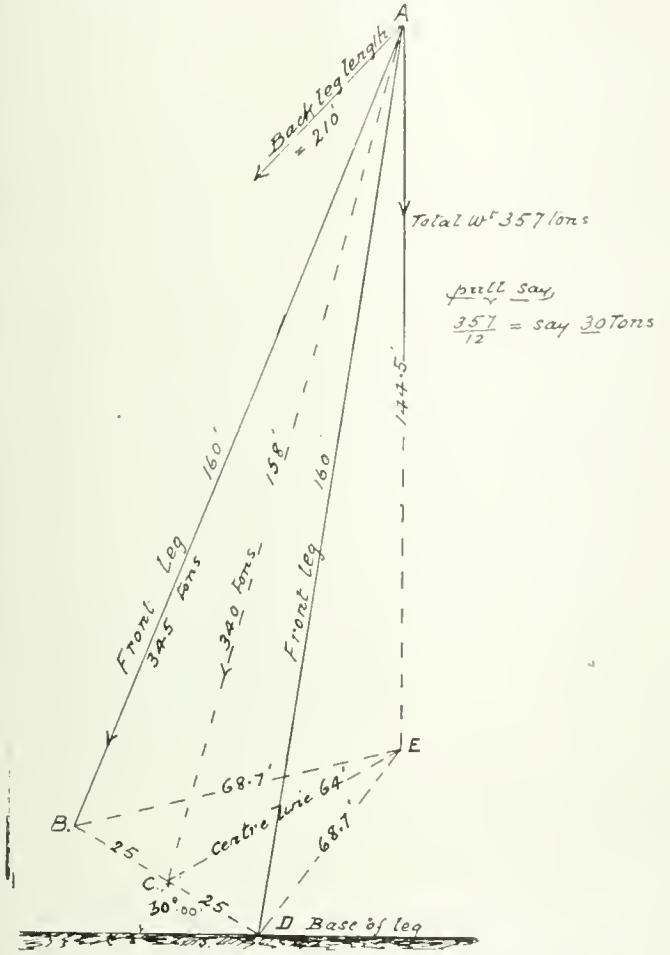

Fig. 2.—Isometric Sketch Showing Deduced Dimensions of Shear-legs.

The two front legs are necessarily close to the edge of the wharf; in the instance under consideration the distance therefrom being five feet. This necessitates a very solid wall and foundation, well tied in to counteract the outward thrusts from the toe of each front leg, while the rear leg is in compression. These foundations are connected to the concrete pit foundations for the back leg screw and thrust block gear by two counterforts, as shown on the plan in Fig. 1. The longitudinal and cross-sections illustrate the piling necessary in this particular case on account of the foundations resting upon "made" ground. The piles were carried down to gravel, as were also the foundations for the counterforts and basin wall, as will be seen in the drawing. Generally the back leg foundations are carried down in concrete unless the solid bed is of too great a depth, in which case footings, proportioned in size to the weight to be supported, would be used. Piling is not used unless absolutely necessary.

In the design the first step consists in fixing the maximum height required. This estimate is based upon the largest weight, the highest lift anticipated, the depth of load, and length of blocks, including tackle. The height, as shown in the diagram, of the case under consideration is 144 feet 6 inches, measured from the ground.

The necessary width between the footings for the front legs and the greatest overhang from the vertical are next deduced. These are found to be 50 feet and 64 feet respectively.

Referring to the isometrical sketch of Fig. 2: $\sqrt{CE^2 + CD^2} = \sqrt{64^2 + 25^2} = 68.7$ feet $= DE$; and $\sqrt{DE^2 + AE^2} = \sqrt{68.7^2 + 144\frac{1}{2}^2} = 160$ feet $= DA$, which is the length of front leg from point D to point A. $\sqrt{CE^2 + AE^2} = \sqrt{64^2 + 144\frac{1}{2}^2} = 158$ feet $= CA$. (See Fig. 2).

The weight of one front leg is arrived at by computing the volume from the dimensions given and the weight at 20.5 lbs. per sq. ft.

Weight of front leg =	51,520 lbs.
Weight of four ribs =	9,280 lbs.
Weight of blocks =	13,120 lbs.
	73,920 lbs. or 33 tons, approximately, (2,240 lbs.).

Allowing for the weight of end blocks, etc., the estimate for each front leg may be considered 40 tons.

The weight of the back leg will be found by proportion to be 52 tons, its length being 210 feet.

The load increased by 50% over load is considered as a test weight = 150 + 75	= 225 tons
Tackle - - - - - - - - - -	= 10 tons
Half the weight of the front legs (considered twice) - - - - - - - - -	= 40 tons
Half the weight of the back leg - -	= 26 tons

making a total approximating 300 tons.

In considering the blocks themselves the double "purchase" must be taken into account, the test weight being $\frac{225}{12} = 19 \times 2$ = 38 tons

Friction, etc. (reckoned at 50%) = 19 tons

making a total of 57 tons, double "purchase," and a grand total of 357 tons, as the weight. The pull would therefore approximate 30 tons, or 1/12 of this.

Resolving the load when overhanging 64 feet, the tension on the back leg reaches 350 tons, and on the front legs 680 tons thrust, or 340 on each, if both were on the centre line (for calculation only), and 345 tons on each when splayed 50 feet apart at base.

Taking the pull into account, a block of concrete of sufficient weight to resist the tension of the back leg at its foot when the weight is at its greatest overhang, 64 feet, must be of the following depth:

$$\frac{189 \text{ tons, vertical pull, } \times 16 \text{ cu. ft. per ton of concrete}}{32 \text{ feet, length, } \times 13 \text{ feet width}}$$

= 7.3 feet. Therefore, the dimensions of the block might be 32′ 0″ × 13′ 0″ × 7′ 6″ depth.

This gives 3,024 cubic feet of concrete required. In the actual case the chosen depth of the block was 10′ 6″, affording an excess volume of 1,344 cubic feet.

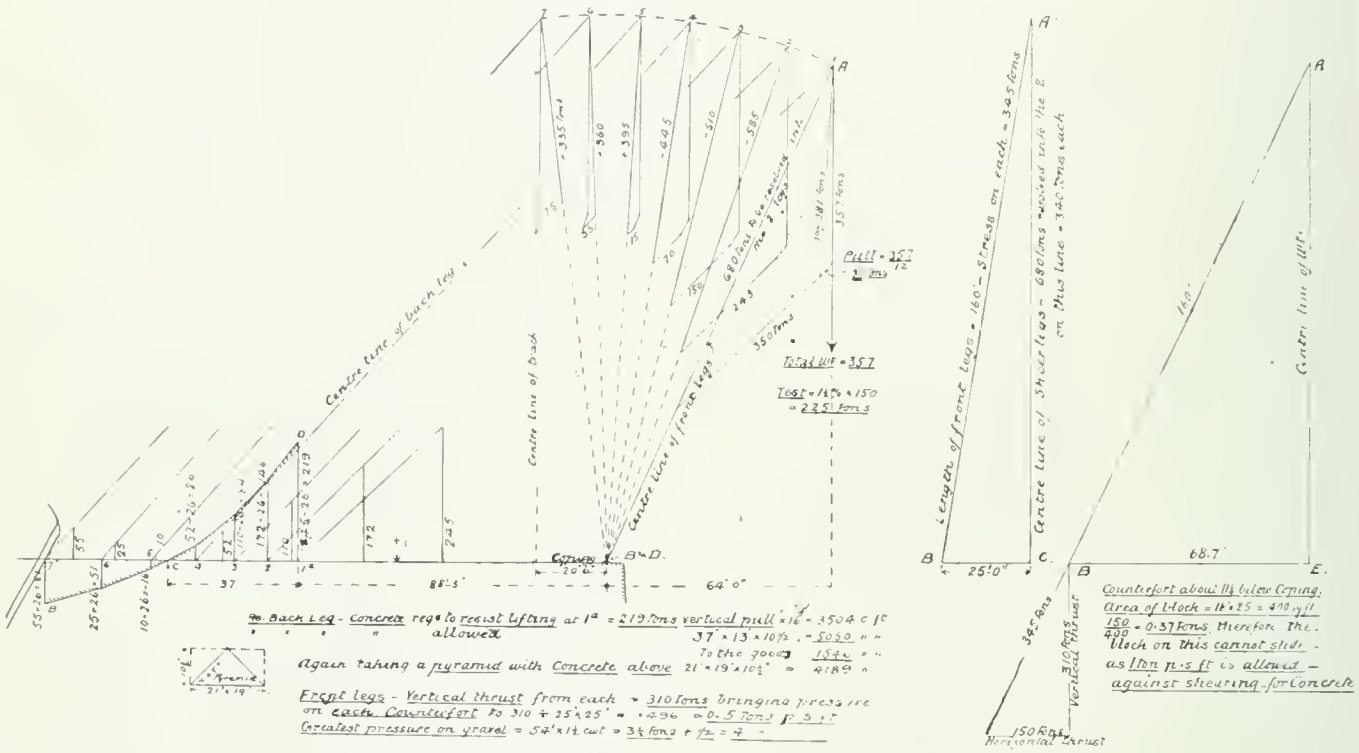
The front leg thrust equals 315 tons; 285 tons vertically and 140 tons horizontally. The sectional area of the top block of the counterfort, about 11′ 3″ below the coping, as shown in the diagram, is about 400 sq. ft. (dimensions 16 × 25). This gives, therefore, 0.35 tons per sq. ft. as the force tending to cause the block to slide. As 1 ton per sq. ft. is safe against this shearing, the factor of safety is sufficient.

Referring again to the diagrams of Fig. 1, one shows the shear-legs run in until the weight hangs over the centre of the track. The stresses at intervals from Fig. 1, 1a to 7, as the thrust block is run backward on the screw, are given. In this case the pull from the winches is taken into account, thereby increasing these stresses. At the points 1a to 7 are shown the resultant vertical stresses, 26 tons, or one-half the weight of the back leg being deducted when the leg is in tension, and added when in compression. This gives the lines *BC* and *CD* when in compression and tension respectively, *C* being the neutral point.

The diagram thus supplies the following data: The block 37′ 0″ in length represents the amount of concrete affected, which also must shear before failing. The pyramid is really a trial block giving a factor of safety of 3.

There are 1,200 cubic yards of concrete in each counterfort wall of the actual case to which this design applied. This includes the basin wall between it and its face. The concrete for the back leg foundations and the two connecting struts amounts to 1,180 cubic yards.

The plan in Fig. 1 also shows the position of boiler, engines and steam winches. They are equipped with centre tunnels, as shown, to provide access to bolts and plates in their foundation beds, it being most important to have all hoisting apparatus carefully and properly fixed in position.



Centre line of back leg
Centre line of front legs
Centre line of track
Coping
B & D
37
88·5'
64'0"
Pull = 157 / 2 tons
Total lift = 357
Test = 14½ × 150 = 2251 tons
Again taking a pyramid with Concrete above
Except legs - Vertical thrust from each = 310 tons bringing pressure on each Counterfort to 310 ÷ 25 × 25' = ·496 = 0.5 Tons p. S. ft
Greatest pressure on gravel = 54' × 1¼ cwt = 3½ tons + ½ = 4 "
Centre line of Shear legs
Length of front legs = 160 - Stress on each = 345 tons
Counterfort about 11½ below Coping.
Area of block = 16 × 25 = 400 sq ft
150 / 400 = 0·37 Tons. Therefore the block on this cannot slide - as 1 ton p. s. ft is allowed - against shearing - for Concrete
150 Tons Horizontal thrust
310 Tons Vertical thrust
68.7'
25'0"

GERMANY'S IRON AND STEEL EXPORTS.

The scale of progress which Germany is making as an exporter of iron and steel is illustrated in the following table, where quantities are in kilograms per head of population, and show a fast increasing margin between home consumption and total output:—

January to May.	Output of blast furnaces.	Home consumption.
1907	85.87	60.64
1908	81.77	52.83
1909	81.69	51.50
1910	92.05	56.28
1911	98.60	59.71
1912	107.83	62.88
1913	119.13	68.08

The most notable example of existing train ferries in Europe are those which have been established by the Danish State railways. The geographical conditions in Denmark have made train ferry transport a necessity for through communication. These ferries give unbroken railway transport over distances ranging from 1½ miles to 26 miles. One, the Sallingsund ferry, has been in operation since 1872, and that across the Storabelt, at a point where the arm of the sea is 16 miles wide between Korsoer and Nyborg since 1883. There is a train ferry between Copenhagen and Malmoe, a distance of 19 miles. The longest of the ferries, that which crosses the Baltic between Warnemunde and Gjedser, carries trains for 26 miles over waters where heavy seas are not infrequent. Some of the Danish ferries provide uninterrupted railway communication only between the separated parts of Denmark; others, of which that from Gjedser to Warnemunde is the most important, provide through railway connection with the railway systems of Europe, with all the accompanying advantages of unbroken goods and mail transport and sleeping-car accommodation for passengers.

A WATER SUPPLY FOR WINNIPEG

A REPORT CONCERNING SHOAL LAKE AS A SOURCE OF SUPPLY FOR THE GREATER WINNIPEG WATER DISTRICT—BY AN OFFICIAL BOARD OF CONSULTING ENGINEERS.

WINNIPEG'S chief problem is that of water supply, and municipal authorities have for years been studying the question of a sufficient supply of safe and desirable water for domestic and industrial use. A year ago *The Canadian Engineer* (issue of Sept. 19th, 1912) published, in part, a report presented by Prof. C. S. Slichter, of Madison, Wis. Shoal Lake was recommended by him in preference to the other possible sources, viz., Winnipeg River, the Poplar Springs, the Crystal Springs, and the artesian well system which, up to that time, was the source of supply. This source provided a water of high mineral content, corrosive and destructive to plumbing, boilers, etc., and generally considered too hard for domestic use, as well as being unsatisfactory from a health point of view. The report referred to pronounced Shoal Lake as a supply not requiring treatment before consumption. Readers are referred to the article mentioned for a concise résumé of Prof. Slichter's recommendations.

This source had already been suggested in 1907 by a commission, but, judging such a project as being too expensive, Winnipeg River was recommended instead. No procedure was made, however.

Mr. H. N. Ruttan, city engineer, suggested last year that steps be taken to have a thorough investigation of the Shoal Lake project, as the question had resolved itself largely into one of cost and an accurate estimate of the expenditure which such a proposal would entail, was necessary before proceeding further. This investigation has been carried on since early spring by Rudolph Hering, Frederic P. Stearns and James H. Fuertes, the board of consulting engineers, and who have just presented their report, which we publish herewith in part:

Quantity of Water Required.—The population of the Greater Winnipeg water district is about 225,000, about 200,000 being in the city of Winnipeg. The rapid growth is shown by the fact that the present population is twice that of seven years ago, and five times that of fifteen years ago. The city and district are now so well established that it is not advisable to adopt a hand-to-mouth policy if it can be shown to be more economical in the long run to provide works of large capacity at the present time. The population of Winnipeg and the amount of water supplied in each year beginning in 1902, is given in Table I.

Year.	Population as shown by assessment records.	Water supplied per day* Imperial gallons.	Imperial gals. per inhabitant.
1902	48,411	1,550,000	32
1903	56,741	1,860,000	33
1904	67,262	2,340,000	35
1905	79,975	3,280,000	41
1906	101,057	3,500,000	35
1907	111,729	4,580,000	41
1908	118,252	4,880,000	41
1909	122,390	5,820,000	48
1910	132,720	5,930,000	45
1911	151,958	6,510,000	43
1912	166,553	7,750,000	47

*The table does not include the small quantity of water pumped at the high pressure fire station for other than fire purposes.

This table shows that the amount of water used per inhabitant is increasing, which is a result to be expected with the increase in the facilities for using water and one which accords with the experience of other cities. The increase is likely to continue until it reaches about double the present amount now used per inhabitant, if the present meter system of selling water is continued, as we believe it should be, or a much larger quantity provided the water is not metered to the consumers.

We believe that 85 gallons per inhabitant is a proper quantity to adopt for estimating the future needs of the district as an average for the year, but in some months the rate will average as high as 100 gallons per inhabitant. Therefore an aqueduct to provide for a considerable time in the future should, in our opinion, be designed with a capacity of 100 gallons per inhabitant, and even with this provision a large reservoir should be built near the city, in the future, to provide for a still higher rate of water consumption during short periods.

The consumption of water at the present time is somewhat restricted by the limited capacity of the sources of supply and will undoubtedly increase to a considerable extent when a new supply with a better water is furnished. For the next ten years, however, the consumption is likely to be less than 85 gallons per inhabitant.

As already indicated, we have found that the best structure for conveying water for the greater part of the way from Shoal Lake to Winnipeg is a concrete aqueduct laid with a continuous down grade, and as such a structure can be built of large capacity for a moderate additional cost, we have designed this structure to carry 85,000,000 gallons in 24 hours, sufficient, on the basis assumed, for a supply throughout the year for 850,000 inhabitants.

This may seem to be an unnecessarily large provision for future years, but it must be born in mind that the additional cost of making such a structure of liberal size is comparatively small while the cost of duplicating such an aqueduct would be large.

We adopted the capacity of 85,000,000 gallons daily after giving due consideration to the many demands for money for public works in a growing city like Winnipeg; otherwise we should have recommended a larger aqueduct, say one having a capacity of 100,000,000 gallons in 24 hours.

From the point near Transcona where the concrete aqueduct ends, to the existing McPhillips Street reservoirs, a pipe is recommended; and a single pipe line of the sizes which now seem desirable will convey by gravity 25,000,000 gallons of water in 24 hours, or nearly three times the quantity of water now used. When necessary, the flow through this pipe can be increased by pumping, or a second pipe can be laid.

Assuming a continuous growth for the Greater Winnipeg Water District, based upon the past growth of the district and the rate at which other somewhat similarly situated cities have grown, the 85,000,000-gallon aqueduct would have sufficient capacity for supplying the district until 1944. Assuming further the introduction of water from Shoal Lake at the earliest practicable date, the aqueduct would supply the requirements of the district for

about 25 years after its completion, and the 25,000,000-gallon pipe line would supply by gravity the quantity of water required for two or three years; but, as already stated, the capacity of the pipe line can be increased by pumping.

Quantity of Water Available from Shoal Lake.—Shoal Lake has a drainage area of about 360 square miles and a water surface of 107 square miles, and is at the same level as the Lake of the Woods, with which it connects at Ash Rapids. No direct measurements of the quantity of water which this lake will furnish have been made, but the probable quantity of water may be inferred from the amount of rainfall in this vicinity and the size of the drainage area and of the lake surface.

Shoal Lake, if separated from the Lake of the Woods, would derive its supply from the rainfall upon the surface of the lake and upon the land included in its drainage area. The rain which falls upon the surface of Shoal Lake is offset in part by the evaporation from the lake, but under all ordinary conditions there is probably a considerable supply to the lake from the excess of the rain over the evaporation. A part of the rain which falls upon the land surrounding the lake is lost by evaporation from the surface of the ground, but such evaporation is not as great as from the lake surface, so that there is a larger yield of water per square mile from the land surfaces.

Shoal Lake is so large that in case the supply to it in any year were unusually small, water stored in it in previous years could be used to make up the deficiency. For example, the quantity of water in a single foot of Shoal Lake is equivalent to about 8.5 months' supply for 850,000 people, at the per capita rate of water consumption before stated.

Quality of Water in Shoal Lake.—Physical and chemical examinations of water taken from Shoal Lake show that it is practically free from contamination, that it is clear and practically without color and that it is free from odor and has an agreeable taste. It is very soft in comparison with the water at present supplied to Winnipeg, and was, at the time we examined the water, of excellent quality for a domestic water supply. The chemical analyses show that it is well suited for boiler and general manufacturing purposes.

Microscopic examinations of the water show, as is the case with the water of all lakes and reservoirs, that the water contains a variety of minute animal and vegetable organisms which can be discerned with the microscope and some of them with the naked eye. The total number of organisms per cubic centimeter has ranged from 249 to 1,776, and averaged 833, which is no more than the amount usually found in small lakes and the better class of reservoirs used for water supplies.

So far as the examinations have been carried, the water has had no disagreeable taste or odor at any time, but it is sometimes the case that these minute organisms increase greatly in numbers and give the water a pondy or even a disagreeable taste. This is not as likely to be the case in large lakes as in small ponds and artificial reservoirs. Many cities take water from the Great Lakes, from Lake Superior to Lake Ontario, and there has been no complaint from bad taste or odors from such waters, although they are not free from microscopic organisms.

There are many other reservoir supplies which contain a much larger number of organisms than has been shown by the recent examinations of Shoal Lake water, and which are nevertheless used without serious complaint on the part of the water takers.

We cannot, in the absence of definite knowledge as to the history of Shoal Lake water, affirm that growths will not occur to cause at times unpleasant tastes and odors, but the results of recent observations and all of the conditions indicate that troubles from bad tastes and odors should be infrequent, and not very serious, if they occur at all.

Having made such an extended reference to these organisms, we wish to state positively that they have no relation whatever to disease germs and there is no evidence that they render the water unwholesome.

Should is ever become desirable to filter the water, either completely, or to the more limited extent required to remove the microscopic and larger organisms, this can be provided for at the site of the proposed reservoir east of Transcona, where an opportunity is also presented for the aeration of the water should this be found advantageous.

Description of Proposed Works.—The main features of the work for immediate construction are:

1. A dyke and channel for the diversion of the Falcon River into Snowshoe Bay.

2. A concrete masonry aqueduct, having a continuous down grade for 84.73 miles from an intake at Indian Bay to a point just south of the Grand Trunk Pacific Railroad, about one mile east of Transcona, the aqueduct having a capacity of 85,000,000 gallons of water daily.

3. A pipe 5 feet in diameter, extending from the end of the masonry of the concrete aqueduct, most of the way through streets to Victoria Park on the west side of the Red River in Winnipeg, this pipe to be of steel except under the Red River, where cast-iron pipe laid in a tunnel is recommended.

4. A 48-inch cast-iron pipe through the streets of Winnipeg from Victoria Park to the McPhillips Street reservoirs. The pipe line will, as stated, have a capacity of 25,000,000 gallons daily.

Estimates of Cost.—Detailed estimates of the probable cost of construction, excluding land acquisition, installations of branch pipes to adjoining communities along the line, water damages, interest charges, etc., are summarized in the report as follows:

85 miles of construction railway	$1,020,000
Clearing	55,000
Ditching	90,000
Telephone line	25,000
12,000 lin. ft. 4-foot cast iron pipe from McPhillips Street reservoirs to Victoria Park at $23.17	278,000
900 lin. ft. tunnel under Red River, including the shafts and the 5-foot cast-iron pipe laid in shafts and tunnel, at $144.44	130,000
43,200 lin. ft. 5-foot steel pipe, extending from the easterly shaft of the Red River tunnel to the junction with the concrete aqueduct about one mile east of Transcona, at $20.74	896,000
447,300 lin. ft. concrete aqueduct, extending from the end of the stel pipe to Indian Bay, with all appurtenances, at $19.51	8,729,000
Falcon River diversion	121,000
	$11,344,000
Add for administration, engineering and contingencies, 15 per cent.	1,701,600
Total estimated cost	$13,045,600

The annual cost of maintenance of the aqueduct and the expense connected with its operation is estimated at $40,000.

Conclusions.—"Briefly summarized the conclusions and recommendations are as follows:

"1. Shoal Lake, without help from the main Lake of the Woods, can be depended upon to furnish, even in the driest years, a large part, if not all, of the water needed

for Winnipeg until the population shall have reached about 850,000, and with the help of the Lake of the Woods can furnish a practically inexhaustible supply.

"2. The water of Shoal Lake was, when we examined it, of excellent quality for domestic and manufacturing purposes, being soft, practically free from contamination, without noticeable color, free from odors and of an agreeable taste. The results of recent examinations of the Shoal Lake water, and all of the local conditions, indicate that the occurrence of bad tastes and odors in the water, from growths therein, should be infrequent, and may never occur at all.

"Should such troubles occur in the future the opportunity to correct them by suitable treatment may be availed of when necessary without interrupting the supply of water to the city or making expensive changes in the works as built.

"3. The best point to take the water is from near the west end of Indian Bay, an arm of Shoal Lake, as the depth of the water and the configurations of the bottom and shores in this neighborhood are favorable.

"4. In order to avoid the dark colored water discharged by Falcon River, and cut off the shallow flowage at the extreme westerly end of Indian Bay, we propose the construction of a dyke across the end of the bay and a canal leading therefrom to Snowshoe Bay, through which to divert the undesirable waters.

"5. We find that the best way to get Shoal Lake water to Winnipeg is to bring it down first through a concrete aqueduct 84.75 miles in length, laid with a continuous down grade to a point about a mile east of Transcona, and then in a 5-foot steel pipe to the Red River. A 5-foot cast-iron pipe, in tunnel, is to convey the water under the river, and thence a 4-foot cast-iron pipe, laid in the city streets, will deliver it to the reservoirs at McPhillips Street. The total length of the aqueduct is 95.35 miles.

"6. We recommend that the concrete portion of the aqueduct be given a capacity of 85,000,000 imperial gallons per day, but that the pipe line portion be given the smaller sizes above stated, capable of discharging 25,000,000 gallons per day by gravity into the McPhillips Street reservoirs.

"7. We recommend taking the water out of Shoal Lake by gravity rather than pumping it over the summit in pipe lines.

"8. We estimate that the total cost to the Greater Winnipeg Water District of building the intake, Falcon River Diversion Works, concrete aqueduct and steel and cast-iron pipe lines, including crossings of streams and rivers, waste weirs, and other appurtenant works, will be $13,045,600.

"This estimate does not include the cost of acquiring land, or of branch pipes to the different communities; neither does it include any allowance for water damages, and for interest charges.

"9. We recommend as a part of the plan, but not for immediate construction, that a new storage reservoir, holding about 250,000,000 gallons, and estimated to cost between $300,000 and $400,000, be built at a point about a mile east of Transcona, and that a main pumping station be there established to force the water to the city through the 5-foot steel pipe, and through branches to be laid to the different sections of the city and district requiring the water. This reservoir and pumping station should be completed and ready for use before the demands for water shall have reached the capacity of the pipe line."

It remains to state that the report has been adopted by the administration and work will proceed without further delay, Winnipeg thus hoping to have, at the end of the five years which it will take to install, a healthful and plentiful water supply.

THE POWER PLANT OF THE CALCUTTA ELECTRIC SUPPLY COMPANY.

There is probably no local undertaking which has contributed more to the comfort and well-being of the residents, in a climate like that of Calcutta, than the supply of electricity for lighting and power purposes. The supply was first started in Calcutta in 1899 from a small non-condensing station. The advantages of electricity were quickly realized, and extensions have been found necessary from time to time. Although branch power stations have been erected at Alipore, Ultadanga, and Howrah, the demand has increased so regularly that it was found necessary to go further afield for a suitable site, one essential being that there should be an ample supply of water for condensing purposes.

The site now used is situated on the banks of the Hooghly at Cossipore, about two miles north of Calcutta, and it is large enough to allow for any further extensions that may be necessary. The distance of the generating station from its main area of supply made a high-tension scheme necessary, the generating being done at a pressure of 6,600 volts, supplying power to various substations in the city.

In the main building there are three 4,000 b.h.p. Oerlikon turbine-driven alternating generators, one mixed pressure turbo of 1,000 b.h.p., and one motor convertor of 600 b.h.p. In the wing are being erected four interpole direct current generators by Crompton and Company, driven by Bellis and Morcom engines of 600 b.h.p. The turbines, of the impulse type, are particularly remarkable for the simplicity of the governing arrangements by which the speed is kept absolutely constant automatically, and can be raised or lowered from the switchboard. The bearings are also self-oiled under a pressure of 60 lbs. of oil, and are so arranged that any interference with the oiling arrangements will immediately bring the machine to rest without damage. The mixed pressure turbine can be used to work from the exhaust steam from the Bellis and Morcom engines, or live steam from the boilers, or a mixture of both, as required.

The switchboard arrangement is a unique piece of work, being fitted with the very latest pattern switches and recording instruments.

In the boiler-house there are five water-tube Stirling boilers, each of the rapid evaporative capacity of 25,000 lbs. of water per hour, at a working steam pressure of 175 lbs. per square inch, with a grate area of 105 square feet and 5,856 square feet of heating surface. They are fitted with the automatic underfeed system of mechanical stokers. In this method of firing the green coal is fed from below and distributed from the centre over the sides of the fire-grates into ash trays which are dumped periodically. Unscreened slack coal of a low grade is being burnt quite smokelessly, even though the chimney is only 100 feet high. When completed the station will have some 18 of these machines installed, capable of burning 300 to 350 tons of coal each 24 hours. Forced draught is used, and there are installed Green's Economizers of 750 tubes in six blocks, three on each side, being in series, with a total heating surface of 7,200 square feet.

DISTRIBUTION OF EXPENDITURES ON COLEMAN TOWNSHIP ROADS FOR SEASONS 1909, 1910, 1911, 1912.

THE following table is an indication of the development of roads in the Cobalt-Haileybury region of the province. The records of expenditures for highway improvement made by the township of Coleman are quite complete as indicated by the data, which we have obtained from the report for 1912 of the township engineer.

Name.	1909.	1910.	1911.	1912.	Total.
Timiskaming Road:					
(a) Overhead Bridge to Giroux Lake Corners	$ 8,328.96	$ 2,592.70	$ 3,136.68	$ 987.80	$ 14,956.14

Fig. 1.—Cobalt-Haileybury Road, Showing Permanent Wall Construction.

Fig. 2.—Section of Roadway Typical of Difficulties in the Construction of Northern Roads.

In his report of work accomplished during 1912, Mr. H. T. Routley, until recently township engineer, outlines in a very interesting way the methods of construction, and data relating to them, of some important roadways in the township. An interesting feature of the report is the exceedingly small requirements for maintenance and repair of the main roads in comparison with conditions pertaining to the cheaper earth roads. The divergence in cost is explained by the fact that all main roads during the past three years were laid with water-bound trap-rock macadam. The rainy season of 1912 is stated to have forcibly demonstrated the fact that where a road is being

Fig. 3.—The "Square," Cobalt, Showing Rocmac Pavement.

constructed for continuous traffic, the best soon asserts itself to be the cheapest. During the greater part of this period it was impossible to keep the unsurfaced earth roads in Coleman township, and throughout the district generally, in good condition, while the main roads, which were properly surfaced when constructed, were in excellent shape throughout the entire unfavorable season.

A few of the difficulties encountered in the construction of these roads is best described by illustrations as

Fig. 4.—Cobalt-Latchford Road.

shown herewith. Fig. 1 illustrates a piece of permanent wall construction on the Cobalt-Haileybury Road. During the year about 2,000 feet of retaining walls from 5 to 10 feet in height were constructed for this purpose.

With the exception of a very small piece of work the construction of these roads and other development work has been done directly on the day-work system. The plan followed was that of engaging carefully picked men and retaining them season after season.

PROGRESS IN THE INVESTIGATION OF THE WATER POWERS OF BRITISH COLUMBIA.

THE fourth annual report of the Commission of Conservation contains the report of its consulting engineer, Mr. Arthur V. White, respecting the work that was accomplished up to the close of 1912, in the Commission's investigation of the water-power resources of British Columbia. As stated some little time ago in *The Canadian Engineer*, Mr. White and his men are at present engaged in a continuation of the undertaking.

According to the report no other province of Canada is confronted with the problem of adjusting so complex a water situation as exists in British Columbia. In the early "fifties," water rights and privileges for mining operations began to be taken up, and, subsequently, other rights and privileges were granted for irrigation in connection with the development of large agricultural areas. All of these rights are now represented by upwards of 5,000 water records, issued under various terms and conditions. In addition, there are others, given later, for water-powers. The applications for waters for all purposes are on the increase. The whole situation is a difficult one, and, until adjudication upon conflicting interests can be had, patience and consideration will be required on the part of the record-holders, and caution, wisdom and courage on the part of the administration. These problems are now being dealt with by the Provincial Government.

The co-operation which the Commission is receiving from the province is worthy of much commendation. Through the Minister of the Department of Lands a great deal was gained by the co-operation of forces, the province advancing $3,450 to cover its portion of the co-operative work. In connection with this Mr. White states that in the United States, much water investigation work is carried on co-operatively between the Federal and State authorities. For example, during the fiscal year 1912, the Water Resources Branch of the United States Geological Survey received for such co-operative work, from the state authorities of California, $25,500; from Minnesota, $16,000; from New York and Oregon, each over $13,000; from Idaho, $12,500, and from Washington, $4,400; while a number of other states contributed lesser sums. All the contributing states thus gave a total of nearly $114,000, and this co-operation has proved of mutual benefit.

It might add a little to the clearness of the report to state that the authorities which exercise jurisdiction over water-powers in British Columbia, are first, the Water-power Branch of the Department of the Interior, which has jurisdiction over the Railway Belt; and second, the Department of Lands of British Columbia which has a Waters Branch dealing with irrigation, and also a separate Lands Department dealing with water-powers.

Railway Belt Water-Powers.—In the report of the third annual meeting of the Commission, it is stated that in initiating the water-power investigation in British Columbia it was decided to begin systematically to cover the territorial area of the province. The area south of the Railway Belt, together with the Railway Belt itself, contains the bulk of the population of the province; it also comprises the water-power possibilities of more immediate economic importance, and, consequently, the investigation was commenced in these districts. A large part of the province south of the Railway Belt, in 1911, was examined by the engineers of the Commission.

Through the courtesy of the Water-power Branch of the Department of the Interior, the hydrographer of the Railway Belt has, during 1912, carried forward an investigation in his territory, and the principal field data respecting the water-powers in this area have been assembled. Most of these data have been reduced to a form readily adaptable for inclusion in the proposed water-power report.

The Kamloops hydrographic office has had a heavy task with its own irrigation and other work, and notwithstanding this, extra effort was made by its staff to further the early collection of water-power information that had been requested. They have secured hydroghaphic data, including measurements of stream flow, for some of the large rivers, such as the Fraser, the North Thompson, the South Thompson, the Columbia, and the Adams.

Columbia River Survey.—The Department of Public Works, Canada, in 1912, commenced an instrumental survey of the Columbia River around the "Big Bend." Through the courtesy of the Department, it was arranged that the Commission of Conservation might attach a man to this survey party, that he might make water-power investigations of the tributaries of the Columbia, using the main survey party as a base for operations. Meantime, however, a new water-power organization had been effected in the Lands Branch at Victoria, which has commenced instrumental surveys of the Pend 'Oreille and Kootenay Rivers, and the results will later be available for our report upon the water-powers of Western Canada.

Further Co-operation.—The Forests Branch of British Columbia has just organized an extensive, systematic survey of the forests of the province, and the chief forester, has arranged to have the skilled men engaged upon this special survey, report specifically upon water-powers observed.

The Surveyor-General of the province has instructed British Columbia land surveyors, who are executing the provincial land surveys, to send in information relating to water-powers. It is to be supplied upon special forms, returnable to the Surveyor-General, when the surveyors are handing in their survey reports.

In the Waters Branch, British Columbia, there is now being compiled a complete, brief tabular synopsis of all records and water reservations issued in the province. These water records, as above intimated, constitute really the underlying basis of the water situation and, in many cases, they conflict with the possible development of power on streams to which they appertain. This tabulation will be available for our proposed report, and will constitute a valuable basic record.

The electric energy inspection branch of the Department of the Attorney-General of British Columbia, is also co-operating to secure some desirable information relating to the hydro-electric power companies now operating in the province.

During 1912, a firm of engineers were conducting a railway survey and taking levels down the North Thompson. It was not possible to send a party into this territory, but through the kindness of one of the members of the firm, data was obtained respecting tributaries of the North Thompson.

The Commission has likewise been fortunate in obtaining a co-operation of engineers engaged upon stream gauging in the United States. The water-power investigations that are being conducted throughout the Western States will afford a considerable body of data. The State of Washington, for example, purposes investigating the rivers in that portion of the state adjoining British Columbia, and the results will be available for the report of the Commission. They will be valuable since they are derived from territory corresponding in physical characteristics to portions of British Columbia.

During 1912 the engineers of the Commission covered a very considerable amount of territory embracing the tributaries of the Fraser River, as far north as the Grand Trunk Pacific Railway. In all about 3,300 miles were travelled by the Caribou party. Work was also carried on along the mainland coast, northwards from Powell River, an examination being made of all streams entering the various inlets. It is estimated that the coast party covered about 3,000 miles, much of which distance was necessitated by the trips in and out of the long inlets.

The season, during which it is profitable to carry on reconnaissance water-power investigations in British Columbia is comparatively short, and it is almost impossible for observers to avoid over-estimating the power possibilities of streams observed during high stages. Engineers doing similar work in the United States experience the same difficulty, and have therefore been endeavoring to do the work, as much as possible, when the streams are approaching their lower stages of flow.

In his report Mr. White strongly recommended a careful survey of the water-powers on Vancouver Island. Some of the streams are important, notably Campbell River. A territory so well confined and relatively of such limited extend should not be subjected to the class of reconnaissance investigation that would be justified for larger areas. Vancouver Island presents an excellent opportunity to make an investigation of its rivers in a manner to yield data of higher standard and thus leave the work more complete, and an example of what might be striven for in other parts of the country.

In the United States there is an increasing tendency to do preliminary work of investigation of power rivers in a more detailed manner; the streams are profiled, and possible dam sites, and storage reservoirs, are contoured. This results—without undue increased cost—in the production of permanent survey records of enhanced value.

In the northern portion of the state of Washington much greater outlay is now being made for water-power investigation and surveys, and it is especially desirable to make corresponding investigations in this country, especially upon waters which flow across the boundary.

The work which is underway during the present season is an investigation of the territory tributary of the Grand Trunk Pacific and the Pacific and Great-Eastern Railways, along with the balance of the west coast, Vancouver Island, and a part of the province lying well to the northward of the Grand Trunk Pacific Railway.

THIRD AMERICAN ROAD CONGRESS, DETROIT.

It now seems assured that the heads of every State highway department, from Maine to California, will personally take part in the Third American Road Congress, in session at Detroit during the week of September 29th, and as a result of this unusual interest, the demand for exhibit space by manufacturers has been unprecedented. All available space has been reserved by nearly one hundred manufacturers, who will display their products, including every kind of road-making machinery, engineering instruments, concrete machinery, bridges, culverts, concrete, wood block, asphalt, tar, and oil preparations.

GEOLOGY IN ENGINEERING WORK.

Engineers and contractors are in the habit of considering a knowledge of geology as having little or no bearing upon their work and, therefore, an unnecessary part of their equipment. Consequently, they are not as well versed in the science as they should be, and few have stopped to estimate how closely it is allied to their own work.

Of course, the mining engineer familiarizes himself with enough geology to give him a working knowledge of the earth's formation and of the characteristics of rocks. This is practical geology that is very necessary to him As some one has put it, "The geologist, purely studious, points out what he has deduced about the construction of the earth; but the engineer makes the mine pay."

For civil engineers the science of geology holds much of importance. The value of a knowledge of it has been brought home to a few by geological contingencies that have arisen in their work and asserted claims for respect. Millions are involved in engineering enterprises, the design and construction of which are greatly influenced by the geology of the country. The Panama Canal and the Catskill Viaduct are instances. In tunnelling, railroading, foundations, water supply, in fact, in nearly all of the applications of civil engineering the science of geology touches. Not exempt is the structural engineer, who finds good value in a knowledge of petrology, whereby he may select building stone free from iron to injure its appearance on exposure, or feldspar that will not disintegrate rapidly under the action of weather.

Here, perhaps, lies the reason why the science has not received more attention from the engineer. In his training the study of geology is derived almost entirely from books, and later he experiences difficulty in recognizing the ordinary formations he encounters, and is unable to foretell with any reasonable assurance what a proposed cutting may contain.

It is geology of such practical value as this which appeals to the engineer and a knowledge of which should be fostered.

The world-renowned Twelfth International Geological Congress came to Canada and its last excursion is nearing its destination. With the close of this month its members will have dispersed, and the Congress will be known as the greatest.

But the event did not receive the attention of the engineers that it should have received. The reason has already been defined. But geology should not be overlooked. Conditions of earth and rock strata in connection with excavation work, qualities of sand and stone used in concrete, the condition of river beds, etc., demand attention. The startling revelations of the excavator emphasizes the diversified tendencies which prehistoric glacial volcanic action has left to be contended with. A little of the indefiniteness of excavation might be dispensed with by a greater practical knowledge of geology and the same applies to many branches of the civil engineer's work.

CLAY IN CONCRETE.

Although the effect of clay on the strength of concrete is not definitely known, its presence is presumed by most engineers to be an element of weakness. While the sand and gravel used in concrete work often contain as

much as 5 or 10 per cent. clay, yet many specifications require a minimum of 2 per cent. Such specifications make it necessary to clean the sand, and as the expense of cleaning is great, it is a question of whether it might not be more economical to use more concrete with a high per cent. of clay, than to remove the clay in order to save concrete. The lack of reliable data along this line suggests the value of more systematic experiments to determine the effect of clay in sand and gravel upon the strength of concrete and mortar.

A few years ago the results appeared of a series of tests performed by Messrs. Richey and Prater in the laboratories of the University of Illinois. They had used cubes containing respectively 0, 6 and 12 per cent. of clay, each series of which were seasoned for 1, 4 and 12 weeks respectively before crushing.

In general, the results of the tests indicated that up to 5 or 6 per cent. the weakening influence of clay is not great. Beyond 5 or 6 per cent. the injurious effect increases more rapidly than the amount of clay. Tests on mortar agreed more closely than those on concrete and indicated that clay up to 5 or 6 per cent. is not only not injurious but is even beneficial to the strength of mortar.

The results with natural cement were less erratic than those with Portland, but this was probably due to differences in conditions rather than to the difference in the kind of cement employed. In the natural cement tests not only was the proportion of cement greater, but the mixtures were wetter than in those with Portland. It is probable that the latter is the more important factor, and the suggestion was made by these men that in future experiments more uniform results would probably be obtained by using moderately wet mixtures rather than dry ones.

The tamping of concrete has much to do with its strength, and in considering the effect of clay in the mixture, it may be well to note that a difference may be observed in the action of different mixtures under the tamping iron. The ease of tamping was greater in the experiments mentioned for the 4 or 6 per cent. clay mixtures than for either the clean or 10 or 12 per cent. Tamping the clean material more nearly approaches the case of tamping marbles, not because the voids are not filled but because the adjacent surfaces are clean and the friction is thus reduced so that it becomes difficult to compact the mass. In the 10 or 12 per cent. mixtures clay was present in excess of the amount required to prevent the slipping of the aggregate under the tamper, and as a result some of the clay was forced toward the surface and clung to the tamper so that tamping became a difficult, as well as a disagreeable task.

From their results the experimenters concluded that since the strength of concrete is not much impaired by even 6 per cent. clay, and since the cost of cleaning sand and gravel to contain only a small per cent. is comparatively great, it is probably more economical to use a little more concrete in the work for the sake of avoiding the trouble and expense of removing all the clay contained in the materials available. In other words, the tests indicated to them that it was unwise to specify for any concrete work a minimum of less than 4 or possibly 5 per cent. clay in the sand and gravel used, when any considerable expense would be incurred to obtain cleaner material.

"COAL RESOURCES OF THE WORLD."

One of the outstanding features of the Twelfth International Geological Congress was the presentation of the monograph on the world's coal resources. It comprises three large volumes and an atlas, specially prepared, and closely related to "Iron Ore Resources of the World," which was published under the auspices of the Eleventh Congress.

The coal resources of the world, as compiled from the reports received from a total of sixty-four countries, amounted to 7,397,533,000,000 tons. Of this total, nearly 4,000,000,000,000 tons are bituminous, nearly 3,000,000,000,000 brown coals of various grades and nearly 500,000,000,000 anthracite. Of the anthracite, Asia with the great Chinese fields has by far the largest supply of any of the great continental divisions, furnishing 407,637,000,000 tons. In bituminous, America leads by a wide margin with 271,080,000,000,000 tons, and is also first in the various grades of brown coals. The world's production for the year 1910 was about 1,145 million tons. Making due allowances for loss in mining and for areas that cannot be economically worked, it will be many hundred years before the exhaustion of the supply may be looked for, though considering individual countries the end is in sight in more than one case.

A TUNNEL UNDER THE ENGLISH CHANNEL.

The question of constructing a tunnel between England and the main land is again engaging the attention of the British Government. The question has a fair amount of history connected with it, as in early days the project was favored by both the French and English Governments. As far back as 1874, the British Foreign Office expressly approved of the idea, but a few years later the military and strategic aspects came to the front, and the general conclusion was reached that the project was not likely to promote, but might seriously hamper, the best interests of the country when considered from a military point of view. Since that time the scheme has been resolutely opposed by every government in office, and it is only during the past few years that it has been gaining favor, and the interest in it reviving.

Expert engineers have expressed the opinion that unbroken rail communication between England and France may be successfully carried out by a bridge, a tunnel, or a train ferry. It has been estimated that $10,000,000 would establish an efficient ferry service whereas a tunnel could not be constructed for less than $40,000,000 and the cost of a bridge would be likely to reach $100,000,000. It is the tunnel, however, that is being most dwelt upon.

EDITORIAL COMMENT.

Owen Sound has received a report from the Hydro-Electric Power Commission to the effect that Eugenia Falls, on the Beaver River, will furnish 1,400 h.p., or with the use of storage basin, 4,000 h.p.

IRRIGATION IN OREGON.*

By John H. Lewis,
Irrigation Engineer, State of Oregon.

IN the state of Oregon, we have but recently passed from the pioneer stage of irrigation development into the more complicated stage of expensive works, shortage in water, and numerous controversies. With only seven people to the square mile (over 500 to the square mile in one county) it is apparent that there is yet much room for development. We expect in the near future to reach that stage of irrigation development where the ordinary summer flow of our streams will be augmented many fold through the release of stored water, as is the case in a number of the older irrigation states.

This transition from the pioneer period of unregulated diversions to that of strict public control of all diversions is not easy of accomplishment. The entire thought and life of the water user must be adjusted to the new order. He must abandon the indefinite miner's inch and think of water in second feet and acre feet. He must respect public and private rights to water and suffer the penalty for violating law. Until the new water user, the courts, and public generally, understand the reasons for each feature of the new system, and appreciate the general benefits to be derived from a strict enforcement of its provisions, it will be difficult for the administrative officials to attain the best results.

The Need of Irrigation.—Irrigation is necessary in Eastern and Southern Oregon, but until recently has not been considered necessary in the northwestern, or more densely populated section of the state. The annual precipitation is unevenly distributed, as illustrated by the government record at Glenora, 135 inches; Portland, 45 inches; Government Camp, 90 inches; The Dalles, 15 inches, and Umatilla, 8 inches; each point being approximately 50 miles west of the one preceding.

In the extensive and fertile Willamette Valley only three inches out of the 45 inches of annual precipitation falls during the summer months, while about 20 inches fall during the winter months. Already several irrigation projects are being constructed with a view to supplement this summer deficiency.

Throughout much of central Oregon, which ranges in elevation from three to four thousand feet above sea level, the precipitation varies from about eight to fifteen inches. This district, which has long been famous as being the largest area in the United States without any railway transportation, is now being rapidly settled, due in part to the active railway construction now under way, to the reduction from five to three years' residence required for homestead entry, to the increase from 160 to 320 acres allowed to each entryman, on non-irrigable land, and primarily to the fact that the precipitation in this vast empire is believed to be ample for dry farming purposes.

With only 686,129 acres of land irrigated out of a total of 61,200,000 acres, and with about 4,000,000 acres susceptible of irrigation, the public has become aroused to the importance of irrigation development in Oregon. It is apparent that from six to ten times the population can be supported on irrigated lands in comparison with an equal dry farming area. As the land to be irrigated is well scattered throughout the dry farming and grazing districts, it is also apparent that the value of such lands will be somewhat enhanced through the irrigation of adjoining tracts.

The courts are becoming educated to the value of water and are now less willing than formerly to grant extravagant claims in water adjudications. If twice the amount of water necessary to produce crops is allowed, it is readily apparent that the ultimate area to be irrigated will be reduced approximately one-half. For this reason the public is vitally concerned as to the duty of water. Public funds have accordingly been appropriated for the making of accurate stream measurements extending over a long series of years, for the making of topographic surveys and river profiles, and for determining the quality of the public waters. There is thus a general awakening among all classes as to the importance of irrigation.

Value of Water.—The value of dry farming land ranges from about $5 to $30 per acre. Irrigated, this land would sell from $40 to $100 or more per acre. Improved irrigated land has been known to sell at from $500 to $1,000 per acre and over. Water has, therefore, considerable value, and water rights and titles are now receiving careful consideration. In some sections one cubic foot per second of water, flowing continuously during the irrigation season, is estimated to be worth approximately $10,000.

The cost of irrigation works has increased from $5 per acre in 1900 to an average of $15 in 1910, according to the government census, and systems are now planned or are under construction estimated to cost $40 to $100 per acre. The amount of water and record evidence of water titles are, therefore, important matters, which are now given serious consideration by the investor, the water user, and the public.

Water Laws.—In 1909, Oregon adopted a water law which is similar in many respects to that now in force in the province of British Columbia. It has in general been found satisfactory to both the water user and the prospective investor, and is not burdensome to the public, as the fees, collected and paid into the State Treasury, have gone far towards meeting the appropriations for its maintenance.

The law deals primarily with (1) the adjudication and recording of rights to water which were initiated prior to its adoption; (2) the granting of new rights, after proper application and record, and (3) the protection of all recorded rights, as well as of the public interest in unappropriated waters. Its administration is in the hands of the state engineer and the superintendents of the two water divisions into which the state has been divided, each of whom has special duties to perform. All important grants or decisions are made by these officers sitting as a board.

This law declares all water within the state to be the property of the public and makes beneficial use the basis of rights to its use. In the water right certificate, which is record evidence of title, this basis is qualified by a definite statement as to (1) the priority; (2) the purpose; (3) the period, and (4) the place of use of water; also by (5) the maximum rate of flow or quantity of water. Such certificate gives also the name and address of the owner of the right, and the stream from which the water is diverted.

Owing to the peculiarities of climate and soil, and to the necessity for diverting water for irrigation and other uses, the strict common law doctrine of riparian rights established by early court decisions has been so modified in recent cases that only the faintest shadow of this conflicting doctrine remains to cloud the horizon of the in-

* Read at the recent convention of the Western Canada Irrigation Association, Lethbridge, Alta., August 5, 6 and 7, 1913.

vestor in water projects. In some of our states the common law doctrine still prevails in modified form and is a serious handicap to the adoption of modern administrative water codes. The Canadian provinces should be congratulated upon the freedom with which they can adopt laws suited to their conditions, without a long period of turmoil and expensive litigation by those who wish for some personal or financial benefit, to have streams flow undiminished to the ocean.

Administrative Problems.—Although our water code has been in effect four years, we are just reaching the point where its practical operation can be observed by the irrigator. All rights to water on a number of streams have been adjudicated and recorded, and water masters mave been in charge of distribution. These water masters are appointed by the Water Board, but are paid by the county court. They are thus not as responsive to orders of the superintendents and the board as if paid directly by such board, and subject to dismissal for cause. Another difficulty has been the requirement of law that water masters should be residents of the district from which they are appointed. This prevents the promotion of experienced men to the more complicated districts.

In defining water rights in Oregon, the Water Board has generally specified a particular rate of flow for a definite irrigation season. Where the amount of water thus decreed was too small to furnish an adequate irrigation head, rotation was authorized. In this way each man could at any time ascertain whether or not his neighbor was taking more than his share. In case of rotation among a group of neighbors, the total quantity of water used by any one should not exceed the sum of that allotted to each. Self-interest will cause each man in such rotation group to see that he gets the total quantity of water his full share of the time. Such a decree is almost self-executing, as the average water user is honest, and will not take more than he is entitled to, if he knows the water supply is now sufficient for all. In Wyoming, where they have had long experience in distributing water, it is the exception rather than the rule to call out the water master to administer such decrees.

For old rights, one cubic foot per second is usually allowed for 50 to 80 acres, depending upon local conditions. All new grants for irrigation purposes have been restricted to the rate of one cubic foot per second to 80 acres. The average irrigation season or time between the last killing frost in the spring and first in the fall, has been carefully estimated from official records, at 120 days. The above rate of flow will deliver during such a period three acre feet of water on each acre of land. This in general is sufficient for alfalfa, the ordinary crop requiring the greatest amount of water.

Much difficulty is encountered in defining and protecting rights on flood water streams. On such the floods run off early in the spring, leaving the stream practically dry during the summer months. Rather than build expensive reservoirs, the pioneer settlers flooded their lands by means of ditches or temporary diversion dams, thus storing water in the soil itself. In most cases but one crop of wild hay, yielding about one ton to the acre, is produced, but under favorable conditions one to two cuttings of alfalfa have been produced.

In such cases, a larger rate of flow is allowed and the total quantity of water for the irrigation season limited to 2.5 to 4 acre-feet per acre. The volume limitation in certain cases has been further qualified by defining the amount in acre feet which can be diverted within any period of, say, thirty days. Such a decree is difficult to enforce. No reliable and inexpensive instrument has yet been devised for automatically recording acre feet. The water master must be employed whether a controversy exists or not, and no water user will know whether or not he is getting the amount of water decreed him, unless he keep an independent record throughout the entire season.

Many water masters will thus have to be employed as each ditch will have to be measured one or more times each day. If the water master is not present when water is being run, his records will be incomplete.

Under such system it will be difficult to convict one of stealing water. It will also be difficult to convince each water user that he has received his full share of water. Such system of defining water in acre feet is more suited to large canal systems where numerous ditch riders are necessary to distribute the water, and where but little additional expense would be entailed in keeping accurate ditch records of the volume of water used each day.

Irrigation by Pumping.—Gravity irrigation under large ditch systems did not become a complete success until the common carrier canal was abolished, and water was made by law appurtenant to the land. Those planning to pump water have not forgotten the early experiences of the water user under such canals where the charge for water, after the expiration of the original short time contract, was increased by the company in accordance with the settler's ability to pay. It is believed that pumping for irrigation purposes will not reach its fullest development until both the power and the water are made appurtenant to the land benefited, either through the district or state ownership and distribution of power.

This question is of particular interest to Oregon for the reason that we have a considerable area which cannot be economically supplied by gravity canals, but which may be irrigated by pumping from adjoining streams, or from underground sources.

Along Snake River, in eastern Oregon, a pumping plant was recently installed for the irrigation of 6,000 acres where the maximum lift was over 100 feet. An irrigation district has been formed for the irrigation of 20,000 acres adjoining the above project where the lift will be 200 to 300 feet, and the land about 2,300 feet above sea level.

In central Oregon there are great interior basins, each containing several hundred thousand acres of level land, where the rain fall does not exceed the evaporation. In most of these basins a limited supply of water is found from 20 to 40 feet below the surface. With a permanent supply of cheap power this water could be pumped for at least partial irrigation of these districts.

Public Interest.—It is the duty of the state engineer to refer to the state water board any application wherein the proposed use conflicts with determined rights, or is a menace to the safety or the welfare of the public. This board can direct the refusal of such application after full hearing, if public interest demands. This feature of the law has recently been upheld by our Supreme Court and marks a distinct advance in water legislation.

In Oregon, we have a number of large irrigation projects which can be developed at reasonable cost. Unfortunately the early settlement in these districts has occurred along the streams and there is a strong natural tendency to complicate and delay the construction of the larger projects through the construction of power plants in the stream channels, or the building of railway lines through available storage basins. If the entire stream

basin were owned by an individual, he would compel the power plants to locate a few miles distant on some tributary of the stream where the water could be used for irrigation after passing through the power wheels, although such construction would be perhaps a little more expensive. He would also compel the railroads to locate their lines around and above feasible power and reservoir sites, in order that the large projects which must eventually be built will not be unnecessarily encumbered, and their construction correspondingly delayed.

The state is endeavoring to look somewhat to the future in these matters as indicated by the above authority granted to its administrative officers for the protection of the public interest.

Public Investigations.—Recently a further step in this direction was taken by our legislature. The sum of $50,000 was appropriated for the making of detailed plans and estimates of cost of a number of these projects, and authorizes co-operation with the United States. The government has allotted an equal amount from the reclamation fund and the investigations are now being carried on jointly. The necessary land and water rights are withdrawn so as to prevent further complications, and it is the intent to assign such plans, and rights to the people forming themselves as a district for the construction of the project, or to private capital, who will undertake to carry out the public plans on terms satisfactory to the people. Failing in this, the legislature has submitted a constitutional amendment for vote of the people in 1914 authorizing the issuance of bonds equal to two per cent. of the assessed valuation of the state for the construction of irrigation and power projects, and for developing the cut over timber and other lands of the state.

In other words, the state is now authorized to make water filings, and to gather all necessary information relative to these large irrigation and power projects, which may be necessary in promoting their construction by either private or public funds. It has also taken the first step looking towards construction with public funds if such action is found necessary.

Speaking for the West generally, water is of more value than land. It is highly important that the people be aroused to the value of public water surveys, and the necessity of securing more complete information as to the duty of water.

NEW SLIDING CAISSON FOR H.M. DOCKYARD, PORTSMOUTH.

Last month Messrs. Swan, Hunter & Wigham Richardson, Limited, launched from their new shipyard at Southwick-on-Wear a large sliding gate or caisson for one of the Admiralty new graving docks at Portsmouth. The caisson was launched on its side owing to the great draft of water required when in an upright position. It was then towed to the shipyard, where it was set upright by adding ballast, and then made ready for the voyage to Portsmouth. The caisson is an interesting steel structure about one hundred feet wide at the top and about fifty feet deep. At the side of the entrance to the graving dock a chamber is built of masonry, and into this the caisson is hauled, when the entrance to the graving dock is to be opened. This chamber is covered by a moveable camber deck fitted with apparatus for lifting or lowering it. The camber deck was shipped in pieces to Portsmouth, and where it will be erected and placed in position.

ECONOMICS OF CENTRAL STATION HEATING.*

By Byron T. Gifford.

THERE are three important branches of central station heating: (*a*)the production of heat units; (*b*) the distribution of this product; and (*c*) making the service attractive to the consumer.

The first of these, the generation of heat, may be handled by three distinct methods: by direct firing, or "straight fuel burning" plants; by an electric generating plant with heating as a by-product; and by a combination of a by-product plant and a heating plant.

Owing to many causes the heating plants of the future will be of the last type. In an arrangement of this kind, electricity, for instance, can be produced much more cheaply than is possible in the most economical electric plant, and there are a number of ways of disposing of this by-product: It may be sold to an existing electric plant at a wholesale rate; a market may be made for it by creating industries requiring a fairly large amount of electricity at a comparatively low price. The author has in mind the case of an industry which has supplied to it 400 kw.-hr. of electricity 20 hours per day, 365 days per year, at less than 1 cent per kw.-hr. The net income to the heating company from this by-product is more than sufficient to meet the payments of the bond interest, taxes and insurance of the entire property. This additional income, amounting approximately to $11,000, is being handled with an increased operating cost of $2,200, as compared with the operation of the plant the year previous when no electric current was generated. With a simple or a twin Corliss engine a kilowatt of electricity can be generated under conditions which exist in the average central heating plant with 45 lb. of steam. Assume, for example, a heating plant serving 200,000 sq. ft. of steam radiation. This load gives an average demand on the boilers of about 40,000 lb. per hour, which, if sent through a simple or twin Corliss engine, will develop 880 kw.-hr. of electricity. Assume that this electricity is sold to some consumer for 1 cent per kw.; at this price 1 cent would be realized for every 45 lb., or 22 cents for every 1,000 lb. of steam delivered to the heating mains before it had left the station. The history of central station heating has proved that a rate averaging 60 cents per 1,000 lb. for steam is reasonable and can be procured from any heating consumer. This would mean 82 cents per 1,000 lb. for the steam generated, which is a good return on the investment.

Heating plants in America at present vary in size from a connected load of 10,000 sq. ft. of radiation to a connected load of 1,750,000 sq. ft. of radiation. These plants are built in towns of upward of 1,000 people.

There are few electric generating plants that can put a kilowatt-hour of electricity on their switchboard below a cost of ½ cent per kw.-hr., and there are also few electric plants that can generate and distribute to the primary side of their transformers for a cost of 1 cent per kw.-hr., especially when the overhead and fixed charges are considered. Heating plants, with electricity as a by-product can do this, and this fact alone will make a place for central heating plants. Some of the larger operating

* Abstract of paper read before the Chicago Section of the American Society of Mechanical Engineers, April 9, 1913.

companies are doing this at the present time and others are building properties to operate along this plan.

Regarding the second point, distribution, in waterworks or in gas properties the losses from distribution consist of leaks and pressure drops due to friction which is caused by insufficient pipe capacities. In central heating there are these two losses to contend with, and in addition the loss from radiation, called "line loss" by central heating engineers. Leaks are a decided detriment to heating pipe line, and the loss from this source is probably more serious than was at first supposed. Assume, for example, a hole ¾ in. in diameter in a pipe line containing steam at 5 lb. pressure. With an evaporation of 7 lb. of water per lb. of coal, this leak will cost 23 tons of coal per month. A leak of this size is equally as detrimental in a hot-water heating system. The loss from friction affects, of course, the initial pressure to be carried on the heating mains, and consequently affects the back pressure to be carried on the engines.

As to the detriment of too high a friction loss, in a 3-in. steam line 1,000 ft. long, carrying 1,000 lb. of steam per hour, the friction loss will be equal under average conditions approximately to 1,460 B.t.u. per hour. This same load carried 1,000 ft. in a 3½-in. line will show a friction loss equal approximately to 500 B.t.u. and a 4-in. line under the same conditions will lose only 240 B.t.u. from friction.

The radiation loss from central heating is even more important than friction loss, from the B.t.u. standpoint. There is a number of styles of underground insulation in use to-day, which lose anywhere from 0.03 lb. to 0.38 lb. of steam per sq. ft. of underground surface per hour.

In order to determine the most economical line to install it is necessary to combine the friction and radiation losses. Take, for example, a demand of 1,000 lb. of steam per hour which must be carried 1,000 ft. A 3-in., 3½-in., 4-in. or 4½-in. pipe will do this work, but the most economical size must be determined. The loss from friction would be 1,460 B.t.u. per hour on the 3-in. line; 500 B.t.u. on the 3½-in. line; 250 B.t.u. on the 4-in. line and 130 B.t.u. on the 4½-in. line.

Assume a radiation loss of 0.05 lb. of steam per sq. ft. of underground surface per hour; the radiation loss from the 3-in. line will be approximately 45,000 B.t.u. per hour; 3½-in. line approximately 52,000 B.t.u.; 4-in. line approximately 58,000 B.t.u.; 4½-in. line approximately 65,000 B.t.u. Combining these two losses, it is seen that the 3-in. line is the most economical to install, provided it does not affect the heating station conditions by causing excessive back pressure on the engine.

Experience has shown that a 3-in. line carrying this load the given distance will have a drop in pressure of about 7 lb., and as it is necessary to have 1 lb. pressure at the end of the line, it means that the back pressure at the station would be approximately 8 lb. If this pressure is excessive it would be necessary to run a 3½-in. line, which would give a back pressure of less than 5 lb. The difference in cost between a 3-in. and a 3½-in. line is comparatively small. The cost of material is somewhat less for a 3-in. line; the cost of labor is approximately the same.

To show the value in dollars and cents of efficiency in underground insulation, a piece of line insulated with a construction that will lose 0.05 lb. of steam per sq. ft. of underground surface per hour may be compared with a line insulated with a construction that will lose 0.14 lb. per sq. ft. per hour. Both constructions are found in everyday practice. For this purpose an 8-in. line 1,000 ft. long will be considered. Such a pipe has 2.25 sq. ft. of surface per lineal foot. In the first case the line loss will amount to 112 lb. of steam per hour; in the second case to 215 ft. Assuming a generation cost of 30 cents per 1,000 lb., in a season's operation (from October 1 to June 1, or 5,832 hours) a line loss in the first case will equal $195 per year and in the second case $550 per year.

The money saved, therefore, will be the difference between these two figures, or $355 per year. This is 10 per cent. on $3,550, an amount which can be spent to install the more efficient construction. Since the difference between these line losses is 0.09 lb. of steam per sq. ft. of underground surface per hour, and since the example assumed consisted of 1,000 ft. of 8-in. line, which is 2,250 sq. ft. of surface, it is seen that for every 0.01 lb. of steam saved on this 8-in. line, approximately $400, or 20 cents per sq. ft. of underground surface, can be spent.

Another interesting example is the comparison of two insulations on an entire underground heating installation. This installation consists of approximately 800 ft. of 12-in. pipe line, 1,200 ft. of 10-in. pipe line, 3,600 ft. of 8-in. pipe line, 4,200 ft. of 6-in. pipe line, and 7,300 ft. of 4-in. line and surface. The number of square feet of underground surface in this system is equal approximately to 30,000 sq. ft. Comparing two insulations, one with 0.04 loss and one with 0.09 loss (difference 0.05) by the following formula which the author has derived, the more efficient insulation in this case will be worth $30,000 more than the less efficient:

$$N \times S \times L \times C$$

where N = the difference between the two insulations in hundredths of a pound of steam lost per hour
S = the number of square feet of surface per lineal foot of pipe
L = the length of pipe
C = a constant based upon the cost of steam per thousand pounds and the number or hours in the heating season.

Where the steam costs 30 cents per 1,000 lb. and the heating season is 5,900 hours, the value of C is 21 cents.

Regarding the third point, making the service attractive to the consumer, it is not necessary, perhaps, to wrap it up in a good looking package, but it is necessary to have it attractive in price and quality. That this class of service is attractive is shown by the fact that central heating plants, with few exceptions, have had no trouble holding their consumers. It is this one fact, as much as anything else, that has put many heating plants into trouble. They have been tempted to serve a larger territory or more consumers than their plants could economically handle, and they have been tempted also to extend their service without due regard to the economics of the proposition.

As to the best method of selling the heating service, experience has shown that the meter basis is the most equitable. The rate will depend upon local conditions. A number of companies are selling steam on the meter basis, with a sliding scale rate; others have devised a maximum demand or readiness to serve rate, both of which work out admirably in practice. The quality of the service is always sufficiently attractive to obtain a large percentage of the possible consumers.

CONCRETE DAM CONSTRUCTION NEAR TRENTON, ONTARIO.

A NEW concrete dam, recently completed on the Trent River, near Trenton, Ont., has some features that may be of interest both in the matter of design and difficulties encountered during its construction. Work was commenced in September of 1912, and the structure was completed early in July of this year, covering a total period of about 10 months. Owing to the mildness of the winter of 1912-13 in that locality the Trent River did not decline to its usual minimum flow for this period, and was, in fact, at flood stage several times during the winter months. This naturally caused difficulty which was unexpected, the most acute being in the last closure of the dam.

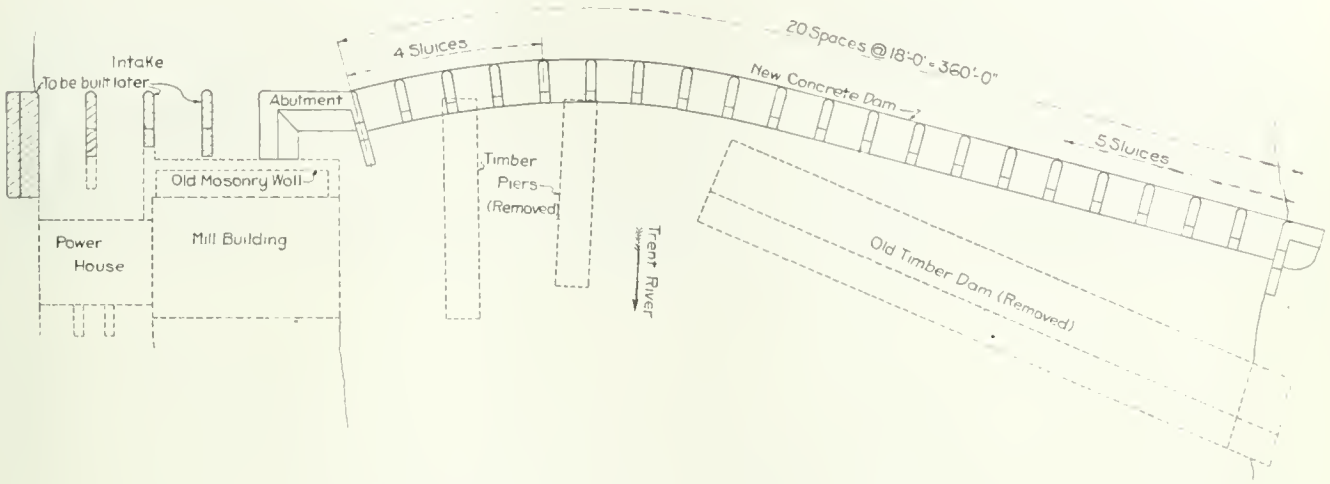

Fig. 1.—Plan of Concrete Dam Across Trent River.

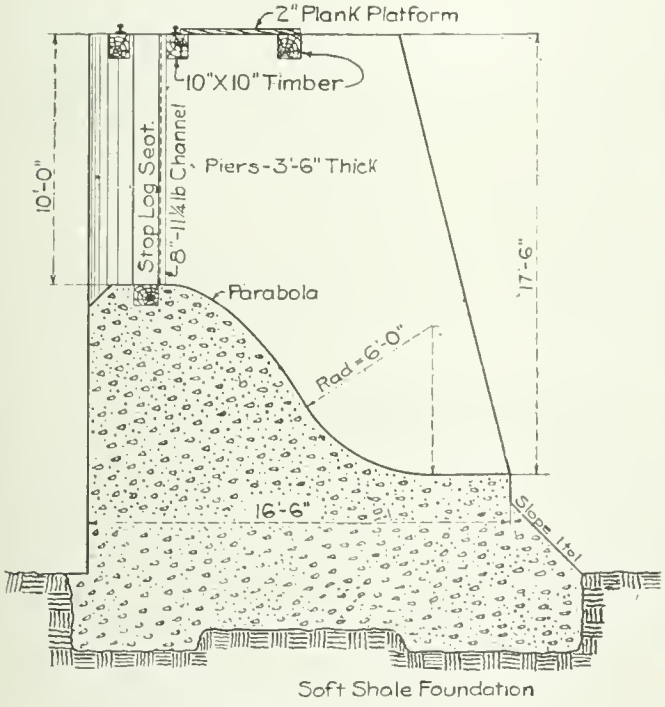

Fig. 2.—Section of Trent River Dam.

The accompanying drawings and illustrations are self-explanatory and need little description of details. The total length of the dam over all as constructed is 425 feet. There are twenty piers, each of which are 3 feet 6 inches and placed 18 feet between the centres. These piers are reinforced with corrugated steel bars which are also extended into the main still-way section. The design is such that stop-logs can be used between the piers to regulate the head as required.

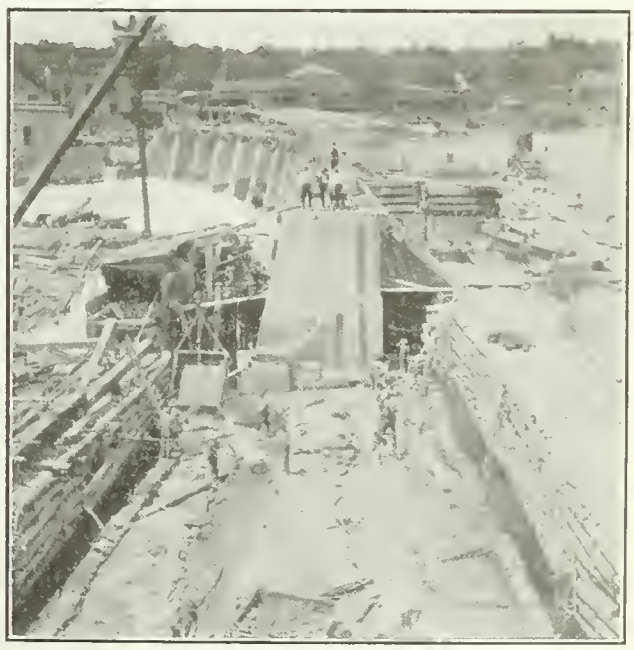

Fig. 3.—Showing Cofferdam After Pumping.

The new structure replaces an old wooden dam that had furnished power for running a paper-box mill at the site. One of the construction problems was that of maintaining sufficient head during the construction of the new dam to keep the mill in continuous operation. This feature was successfully carried out, although it increased the cost of construction somewhat on account of the required extra height of coffer-dams required. The extra outlay was fully justified, however, as otherwise the prospective loss that the mill would have sustained, had it been obliged either to close down operations or to install steam machinery and equipment for the power, would have amounted to many times the sum.

Fig. 1 shows the general layout of the new dam and its position relative to the old structure.

In order to give a greater latitude for operations and to increase the amount of water which may be safely carried over at plug stages there are four openings in the section of the dam adjacent to the mill and five at the opposite end, as the drawing illustrates. These openings have a crest whose elevation is 3 feet lower than that of the remainder of the still-way.

Fig. 2 shows a section of the dam and Fig. 3 gives a general view showing the first section of the proper dam completed. A section of the old wooden dam is shown in the foreground with 2 feet of flash boards in place, in order to maintain the operating head at the mill wheels.

Fig. 4 is a view looking west from the top of the eastern bank of the river and shows clearly inner cofferdam unwatered and excavation for the foundations of the dam in procedure.

The dam was designed and constructed for Miller Bros., Limited, of Montreal, by Walker & Company, Limited, also of Montreal. Mr. W. F. Farley, A.M.Am.Soc.C.E., was responsible for the details of design and Mr. F. E. Cushman superintended the construction, both under the direction of Mr. G. R. Heckle, M.Am.Soc.C.E., who has courteously supplied us with the information and illustrations forming this article.

Fig. 4.—General View, Showing Method of Procedure.

THE EFFICIENCY OF THE AUTOCLAVE TESTS FOR CEMENT.

A greater part of the volume of the consideration which has been given throughout the past year to the application of Portland cement, has dealt with the so-called Autoclave or high pressure steam test as specified for construction work on the Delaware Lackawanna and Western Railway. The attention which this method has received from engineers, cement manufacturers and various technical and scientific associations crystallized into a most important discussion at the convention of the American Society of Testing Materials at its meeting in Atlantic City last June. A paper entitled "The Results Obtained with the Autoclave Tests for Cement," was presented by Mr. H. J. Force, chemist and engineer of tests for the above company and the lengthy discussion which followed his outline of the latest results obtained in the laboratories of the road has added somewhat to the information on the subject although no basic conclusions were arrived at, but rather a clear intimation displayed that no results yet obtained have been sufficiently authoritative as to demonstrate its value. And although the discussion of the test has not been allowed to become dormant, the consideration given it has not disclosed many opinions favoring it, other than the few expressed at that time.

The paper was considered one of the most interesting of the meeting, the discussion following it was unusually thorough.

As described by Mr. Force the autoclave test is made as follows:—

Three neat briquettes are made up, using water which gives a normal consistency on the Vicat needle of from 7 to 10 mm. The briquettes are kept in the damp closet for twenty-four hours, at the expiration of which time they are removed from the molds and placed in the autoclave. Sufficient water is added to partly or wholly cover the briquettes, and the instrument closed. The burners are of sufficient size to raise the pressure to 295 lb. in not more than one hour and this pressure is maintained for one hour longer, or a total time of two hours. The pressure is then gradually released, the briquettes are taken out and placed in the moist closet for one hour. They are then broken in the standard cement testing machine in the usual manner. The results from the various mills are the average of three briquettes.

A 1 x 6-in. expansion bar is made up with the briquettes and at the end of twenty-four hours is measur-

ed and placed in the autoclave. The bar is removed with the briquettes at the end of the two-hour test. The final measurement is made after the bar has remained in the moist closet for one hour.

The tables show the results of all tests on the cements from Mills 1 to 5 respectively. (Two of the tables, showing tests of cements from Mills 1 and 2, are omitted here. All samples, representing 344 cars of cement, passed the autoclave test.) For purposes of comparison, there are shown in Table 4 the averages of the results of all tests from each mill.

Results of Tests.—Each shipment from Mill 2 showed a large increase in tensile strength in the autoclave test and with one or two exceptions the expansions were all very low. The chemical composition of the cement from this mill is about normal. The tensile strengths for the sands on the 7 and 28-day and the 3- and 6-month tests were all excellent.

Mill 1 shows, perhaps, the most uniform results of any of the five mills. This is the first mill in the United States to attempt the manufacture of autoclave cement and is the plant at which many of the early experiments were conducted. From the day that they started to make shipments of autoclave cement up to the present time there has not been one single cause for rejection and this is indeed a most remarkable showing. Mill 1, like Mill 2, shows a continual increase in the tensile strength up to six months.

Mills 4 and 5 also show a wide variation, some of the shipments passing the test, others failing; some showing little expansion, others showing considerable expansion. The results of the 7 and 28-day and the 3 and 6-month tests are lower in this case than in either Mill 1 or 2.

The method of making briquettes used in the laboratory of the Lackawanna Railroad is one of tamping. About 9 per cent. of water is usually used and the briquettes are well tamped in the molds by placing an iron die thereon and striking it several times with a wooden mallet. This gives higher results on the 7 and 28-day tests, but when the briquettes are very firmly packed in with the thumbs there appears to be very little difference in the long-time tests, except possibly that more uniform results are obtained by tamping.

Reasons for Failure Under Autoclave Test.—To all large users of cement the figures from the various mills are certain to be interesting. The question naturally arises as to why a cement which passes the ordinary boiling test in many cases, from some of the mills, shows a decrease in tensile strength or goes entirely to pieces in the autoclave test.

Samples of cement which have failed in the autoclave test, when re-tested again after a period of 30 days, 2 months, 6 months and over a year, in most cases pass the autoclave test. In one or two cases samples which were approximately 15 months old still continued to show no increase in tensile strength; in a few other cases a decrease in tensile strength was shown, while others showed an increase, due to the seasoning process, of over 100 per cent. This points very clearly to the fact that these particular samples were not properly manufactured, for with certain mills any cement which has not passed the autoclave on the first test has in practically every case passed the test after the cement is held for a period of time.

Fine Grinding.—Further investigation as to why some of these cements fail to pass this test after a period of time shows that the raw material was more coarsely ground than in other samples which did pass the test after seasoning. The grinding of the raw material and the proper burning play a most important part in the quality of Portland cement; and the author believes that the failure of cement to pass the autoclave test is due very largely to the coarser granules which do not become hydrated when the cement is set up and that the failure of these granules to become fully hydrated is due to their chemical composition. That is, the granules are composed largely of dicalcium silicate ($2CaO\ SiO_2$), with a smaller proportion of tricalcium silicate ($3CaO\ SiO_2$). Granules of this composition fail to properly hydrate in the period of twenty-four hours and consequently, when brought in contact with the heat and pressure, together with moisture, slaking of the dicalcium silicate is quickly brought about, with the result that a large percentage of expansion occurs, together with a proportionate decrease in tensile strength. On the other hand, if the proportion of tricalcium silicate is largely in excess of the dicalcium silicate, then we may expect a more stable product and one which will show considerably less expansion under the autoclave test and remain constant in volume in after years.

In order to produce a large excess of tricalcium silicate two things are necessary—the raw material must be more finely ground and the cement must be burned at a higher temperature. Most of the cement in Mill 2, as well as in Mill 1, shows very little expansion and a comparatively low loss on ignition. It is also known that in both Mills 1 and 2 the raw material was very finely ground. In some of the other mills—for example, Nos. 3 and 4—while the burning was good, the raw materials were not so finely ground; in Mill 5 there was not only fairly coarse grinding of the raw material but there was also a much higher loss on ignition. From the report of Mill 5 it is evident that the cement from this mill could not be as constant in volume as that from Mills 1 and 2.

In order to manufacture a cement which will pass the autoclave test it is necsssary to grind the raw material very much finer than is customary and to have the clinker well burned. The manufacturer, however, can greatly increase the output of his mill by grinding his raw material coarser and burning his clinker not quite so hard. This produces a cement which contains a very large percentage of dicalcium silicate, which may not be constant in volume, and which would more than likely fail to pass the autoclave boiling test. This cement would probably require seasoning in order to make it pass the regular boiling test.

Future Tests.—Briquettes for tensile strength from the various mills have been made up on most of the samples shown to one year. It is to be expected that the results on cement for longtime tests will be equally as high, if not higher, than on the standard-specification cements. On the long-time tests for expansion very little difference or variation has been noted to date. A number of expansion bars have been kept under observation and measured at frequent intervals. It is believed that some time must elapse before any difference will be noted in these bars.

A large number of cylinders and cubes have been made up for compression tests. The results to date indicate that higher compressive strengths are being obtained, as a rule, on autoclave cement. A large number of 2-in. cubes of the various brands have been made up for compression tests, to be made during a period of from one to five years. The number tested to date is not sufficient to draw any definite conclusions, except as stated above, that in many cases the autoclave cements show higher strength in compression. The results obtained on autoclave cements are more uniform than on other cements.

Discussion of the Paper.—Dr. A. S. Cushman, director of the Institute of Industrial Research, Washington, in presenting his discussion gives some historical data in connection with the autoclave test. It appears that the high-pressure steam test on Portland cement was first recommended in Germany in 1881 by Dr. Erdmenger. His test was fully investigated by some of the leading German authorities on cement and was rejected by them as inadequate and misleading. The International Association of Testing Materials is also mentioned by Dr. Cushman as having reported against the test because it had been found to lead to erratic and inconsistent resource. He likewise refers to a number of researches on the subject, tending to condemn the test as irrational and one not to be used as a method of judging behaviours in construction work of a given brand of Portland cement. He cited tests which go to show that the autoclave process is not able to distinguish between the strength developing qualities of cement up to six months under normal exposure to out-of-door conditions.

In conclusion Dr. Cushman says:—"A careful examination and analysis of all the data obtained in various laboratories and the experience of the Institute of Industrial Research, gained during a systematic investigation of the autoclave test, show that it yields erratic results and is not to be depended upon for determining a quality or condition of any brand of cement either for immediate or future results in service. The conclusion which must be reached as the result of these investigations is that the test is not dependable as a method of distinguishing cement which will give successful results from the cement which may be expected to fail under service conditions."

Av'ge	310	314	49.06	66.80	1.52	320	392	453	447

Mr. Rudolph J. Wig, Assistant Engineer of the United States Bureau of Standards, stated in his discussion that his criticism was based upon tests made by that Bureau over a period of nine months. He drew the following conclusions from these tests:—

1. Of the 48 brands tested, 88 per cent. passed the autoclave requirement upon some tests; 52 per cent. passed upon all tests; and 6 brands failed upon all tests.

2. There is no difference in linear expansion between set cements of types 2 and 3 (unsound and sound, respectively, under autoclave test) which are exposed in the atmosphere for 6 months.

3. Nor is there any difference in linear expansion in these cements when exposed to fresh water for 6 months.

4. The linear expansion of different cements varies from 0.135 to 4.2 per cent. of the original length when exposed to steam at pressures between 180 and 300 lbs. per square inch. The Type 3 cements had an expansion below 0.2 per cent., and the Type 2 cements had an expansion above 2 per cent.

5. The linear expansion of set cements exposed to steam increased slightly as the steam pressure was increased. (Samples tested show an average increase of 0.02 of 1 per cent. for pressures ranging from 100 to 275 lbs. per square inch.)

6. Set cements shows very little change in volume upon storage in air or water after being subjected to high-pressure steam.

7. Samples of apparently sound cements and concretes have been taken from structures 1 year or more old, and found to disintegrate upon being subjected to high-pressure steam. Samples of concrete of poor quality have been taken from structures 1 year or more old and found to show no physical change upon being subjected to high-pressure steam, while other samples of concrete of apparent poor quality entirely disintegrated.

8. The expansion of a 1:1 or 1:2 cement sand mortar made with Type 2 cement exposed to high-pressure steam, shows more than 50 per cent. of the expansion of the same cement neat exposed to high-pressure steam.

9. Of cements which are normally unsound in the ordinary atmospheric steam or autoclave steam test, if the finer size particles are removed, they will be found more sound if tested in the same manner as the original cement, and in many cases entirely sound. While fineness is not essential to soundness, it is the coarser particles of a normally unsound cement which cause the expansive action.

10. A cement originally unsound in the autoclave test will usually become sound in 2 to 6 months.

11. If the cement hydrated and formed into a test piece while it is unsound, it will not become sound upon aging for several months, even though the test piece is stored in water.

12. The maximum tensile strength of sound cement exposed to steam appears to be attained at a pressure not exceeding 150 lbs. per square inch.

13. The compressive strength of concretes made from the three types of cement—No. 1 cement failing to pass the standard atmospheric steam test; No. 2 cement passing the standard steam test, but not passing the autoclave test; No. 3 cement passing both the standard steam test and the autoclave test—show a tendency for Type 1 cements to develop the least strength and Type 3 cements the greatest strength, although the range of values is not very great, and these results should be considered somewhat tentative.

Sufficient data has not been advanced to justify a conclusion as to the merits of the proposed autoclave test of cement, or to warrant its adoption into a specification; but further investigation should be made and due consideration given to a hot test of greater severity than the present standard steam test.

Mr. L. R. Ferguson, Assistant Secretary of the Association of American Portland Cement Manufacturers, and Mr. Henry S. Spackman, consulting engineer, both of Philadelphia, Pa., also took an important part in the discussion, their remarks indicating that those cements which failed under the autoclave show a higher strength in 6 months than those which passed the test. In other words, the very paper advocating the new test has internal evidence which indicates that the increase in strength in the autoclave has no relation to the strength in a structure. Moreover, the results obtained by the experimenters are exactly what were to be expected, for the Germans, after an experience with the high-pressure steam test, concluded many years ago that it was of no value.

While, therefore, those participating in the discussion did not entirely condemn the test, and indicated that they would pursue their studies farther in order to determine its value, those who have been disturbed by recent agitation as to the adequacy of the present specifications

Table 4—Average of Results of Tests from Mills 1 to 5

Mill No.	Tensile strength, neat, at 24 hr., lb. per sq. in.	Autoclave test: Tensile strength, lb. per sq. in. 5.....	210	314	49.05	66.80	1.52	320	392	453	447

may rest assured that the autoclave method has so far failed to demonstrate its value. There is nothing to prove that a cement bought under autoclave specifications is superior to one passing the standard specifications but failing under the autoclave test.

ALUMINIUM INDUSTRY IN INDIA.

The working of aluminium in India is making rapid headway, and promises to become one of the most important industries of the country. The most important potential use of aluminium in India is in making vessels for carrying water to the native houses from the village taps or hydrants or from wells and rivers. On account of caste rules or prejudices, natives of different castes living in the same neighborhood must often go long distances apart in order to secure water not defiled or monopolized by other castes or outcastes, and as a rule not only the poverty of most of the people, but also their religious prejudices prevent the connection of their houses with central taps. When the natives are extremely poor they use earthenware vessels, but as their means increase they adopt the use of metal ware for carrying their water. In a prosperous community the vessels are commonly of copper or brass, but the advantages of aluminium for this purpose are becoming recognized, as it is not only much lighter to carry, but also much cheaper. An aluminium vessel of carrying capacity equal to one of brass or copper would be much cheaper, even if the same prices per pound were charged for the metal. Many metal dealers are now specializing in aluminium goods, and it is said that their profits are very large. Generally speaking, they can allow themselves a much wider margin of profit than is obtainable for brass or copper ware. Another important and rapidly extending use for aluminium in India is in manufacturing cooking utensils, especially kettles, gridirons, saucepans, stew pans, frying pans, etc.

Lockwood, Greene & Company, architects and engineers for industrial plants, with headquarters in Boston, have incorporated a Canadian company, and are opening an office in Montreal.

A COAL TESTING PLANT FOR THE SASKATCHEWAN GOVERNMENT.

A plant is about to be erected by the Saskatchewan government at Estevan for the purpose of developing and testing the lignite coal of that district. The plant will be in charge of Mr. S. M. Darling. The following short account of what he has accomplished with North Dakota lignite is especially interesting to us in view of the fact that the lignites of Southern Saskatchewan and of North Dakota are of the same cretaceous character.

The chemical composition of these lignites precludes their being successfully briquetted in their natural condition. To market the lignite commercially in a large way it must be destructively distilled, carbonized or partially carbonized, and the resulting gas, oil or tar, ammoniacal liquor and carbon residue utilized separately.

Analysis of a large number of samples of North Dakota lignite averaged on a dry basis; volatile matter 40.67, fixed carbon 53.33, ash (practically no sulphur) 6.00.

On carbonization, the products in round numbers are:—

1. Gas, per ton of lignite ..... 10,000 cubic feet.
2. Oil or tar per ton ..... 20 gallons.
3. Ammoniacal liquor ..... 35 gallons.
4. Carbon residue ..... 1,200 pounds.

The yields of gas and oil depends largely upon the temperature and rate of carbonization. With a high temperature and quick carbonization the yields of gas will be high and of oil low; while with a lower temperature, and longer time in which to carbonize. there will be less gas and more oil.

The gas has a heating value of 450 British thermal units per cubic foot. It contains a good percentage of illuminants, but has about fifteen per cent. of carbon dioxide, which almost entirely destroys the illuminating power. This carbon dioxide can be removed by passing the gas through lime, but the process is too expensive for commercial application. The gas can be used as an illuminant by burning it in a mantle, but it is serviceable principally for fuel and power.

There is more gas in one ton of lignite than is required to carbonize the next ton. In practice only sufficient gas is removed to supply the requisite fuel to carry on the process. The remaining portion of the volatile is left to add heating value to the carbon residue.

There is therefore no charge for fuel in the process.

On distillation the oil yields:—

Light oils, benzine, toluene, etc.	11.5 per cent.
Carbolic, oils, some naphthaline	11.5 per cent.
Creosote oils	36.1 per cent.
Anthracene, some paraffine	18.4 per cent.
Pitch, hard	22.4 per cent.

This oil or its distillates can be put to many uses—fuel oil, creosoting oil, leather preservative, waterproofing, pitch, etc. Upon exhaustive distillation it yields aniline dyes, carbolic acid, and in varying proportions all the other coal tar products.

The ammoniacal liquor yields some acetate of lime, or if desired, acetic acid, and about 15 pounds of sulphate of ammonia per ton of lignite. There is a growing market for all of these materials, particularly the sulphate, as fertilizer.

The lignite crumbles on carbonization, which renders possible a continuous carbonizing process, obviating the laborious charging and drawing of retorts, as practised in coal gas plants.

The cretaceous lignites retain largely their original woody structure, and hence do not break up so finely during carbonization. After removing by means of screens the small percentage of fines after carbonization, there remains practically lump charcoal of one-half to two inches in size. This can be used in gas producers, under boilers, and for domestic purposes. This lump charcoal is of about the same analysis as anthracite and has about the same heating value, but is not so dense in structure and therefore has somewhat more bulk per ton than the anthracite.

The fines have to be briquetted, or still further pulverized and burned as powdered fuel, a practice which is rapidly gaining favor.

Actual briquetting and burning tests of this fuel in carload lots demonstrate that satisfactory briquettes can be made with not to exceed 2 per cent. of starch and 6 per cent. of coal tar or lignite pitch as binder.

The briquettes burn with a short flame, no odor, no smoke and no clinker. They can be used wherever anthracite or bituminous coal is burned. They retain their structure in the fire until completely burned. They do not disintegrate or lose value in the weather, and can therefore be shipped any distance without loss.

The lignite coke is an ideal gas producer fuel. A satisfactory gas producer generating gas for power purposes from fuels containing a large amount of volatile, as does the raw lignite, is not available. But with the volatile removed, this lignite coke, transformed into producer gas and used in a gas engine to generate electricity, effects an enormous saving over the present method of producing electricity by means of boilers and steam engines. The gas producer requires only about one-fourth the fuel necessary with boiler and engine to produce an equal amount of horse-power. This producer gas also is an exceptionally good fuel for burning brick, tile, etc.

The matter of a large central power plant at the mines to generate electricity for transmission over a wide radius is essentially one of the quantity of current that can be sold, distance that it must be transmitted and evenness of load. If the current must be transmitted a long distance to a large centre of population there must be intermediate towns at which substantial quantities can be sold. This is simply a question of population. Of course, with cheap power available manufactories and people. to use it will come rapidly But, while the time is near when such a central power plant will be the logical thing, heed must be given also to the large demand for solid fuel, for gas producers, boilers and domestic purposes. Any large installation, therefore, would have as products not only electrical current, but coke, briquettes, fuel oil and other by-products resulting from the carbonizing process.

To defray the cost of carbonizing and briquetting there is the revenue from the by-products, and it is known that the income from this source will at least meet that charge. But aside from this, there is to be derived from this carbonizing process the enormous benefit afforded by the possibility of mining and shipping lignite the year round because the product is put into a condition which prevents deterioration no matter how long the fuel is stored or how far it is shipped.

The Lancashire Dynamo and Motor Company of Canada, Limited, have moved to new premises at 107 Duke Street, Toronto.

A French process of "electrocuting" timber is declared to give perfect seasoning in a single night. With lead plate electrodes on each side the timber is placed in a solution containing 10 per cent. of borax, 5 per cent. of resin and a little soda, and application of the current expels the sap and fills the wood cells with the borax and the resin.

EXPERIMENTAL MINE EXPLOSIONS.

Coal dust explosion tests in an experimental mine are dealt with in Bulletin No. 56 of the United States Bureau of Mines for the purpose of placing before mining men an account of the objects sought in the establishment of the experimental mine of the bureau. A description is given of the arrangement and equipment, and a detailed account of the first series of explosion tests, with explanatory notes concerning recording apparatus, etc.

Particularly interesting is the information which. the bulletin contains concerning the mine and its operation. The requirements considered in connection with the selection of the mine site were:—

It should be in a coal bed, the dust of which was inflammable; the mine should be naturally dry and self-draining; its openings should be drifts to avoid complications of shaft-wrecking; the mine should be practically free of explosive gas; a supply of natural gas should be available, so that tests with gas could be made if desirable; a good boiler-feed water supply should be available; and mine should be near a railroad, but at some distance from dwellings.

These requirements were met in the selection of the site at Bruceton, thirteen miles from Pittsburg. Development was begun in December, 1910. The mine at the time the first tests were made, which were considered to be preliminary tests, consisted of two main parallel entries a little over 700 feet long, nine feet wide, with a forty-one foot pillar between them. The entries were connected with cut-throughs every 200 feet. A diagonal heading 198 feet long connected the air-course at a point 117 feet from its mouth to a third. opening. Ventilation was furnished by a small fan at the top of an air-shaft, which is offset six feet from the air course fifty-five feet from the opening.

The main entry was lined with reinforced concrete for the first 169 feet, and a strongly reinforced concrete portal constructed at the main opening. Five rows of shelves, three inches wide, were installed on each side of the main entry. The explosions in the first series were originated by blown-out shots of black powder from a cannon at the face of the entry or a pipe embedded in the coal. The shock wave from the shot would blow up the coal dust from a bench in front of the shot into a cloud and ignite it. Beyond this point the coal dust previously placed on shelves in like manner would be thrown into a cloud in advance of the flame and in turn be ignited.

At various points along the main entry instrument stations had been constructed in the coal rib, which were separated from the explosion gallery by heavy steel plates. Four types of instruments were used in recording the results of the explosions. Pressure manometers were used to give a record on a revolving smoked paper of the variation in pressure at the particular point. Pressure circuit breakers, installed in the stations, were connected to recording apparatus in an outside observatory by means of wires passing through a pipe embedded in concrete in a groove in the coal rib. When the circuit breakers were acted upon by a certain pressure the circuits were broken, the time of the breaks being recorded on a moving paper strip in the recording instrument at the surface. This permitted the determination of the velocities of the pressure wave between different stations. In like manner the velocity of the flame is obtained by a series of flame circuit breakers installed in the various stations. In addition, maximum pressure gauges measured, by the compression of copper cylinders, the maximum pressure exerted at various points.

The first series consisted of fifteen tests. Several of these were given before large numbers of spectators, that of December 30th, 1911, before about 500 persons. A large part of the value of this series was the educational work performed in convincing many persons who still doubted the explosibility of coal dust, that violent explosions could occur without the assistance of inflammable gas in the air. Apart from this result the tests were chiefly valuable in trying out the mine conditions and the various pieces of recording apparatus. Practically all of the tests were made for the purpose of obtaining information with respect to the phenomena accompanying the explosions. For this reason there was little opportunity for studying preventatives. The Taffenel barrier, with a load of shale dust, was not tried in the direct path of the explosion, but was installed a number of times in the air-course parallel to the main entry. The results were inconclusive as to its value.

Each of the explosions is described in detail in the bulletin as to origin of explosion, character of igniting shot, quality and quantity of coal dust used, nature of preventative, outside manifestations of the explosion, inside observations after the explosion, length of flame, and character of records obtained. Analyses of coal dust after the explosion, soot, coked dust, and mine air before and after the explosions are included in the description of the tests.

CHANGE OF NAME FOR NOVA SCOTIA FIRM.

The William P. McNeil and Company, Limited, of New Glasgow, N.S., have announced a change of name to that of the Maritime Bridge Company, Limited. The executive and directorate of the new firm is as follows:—Executive—Walter McNeil, president; Kenower W. Bash, vice-president and manager; Robert C. Grant, secretary. Directors—Francis C. McMath, president Canadian Bridge Company, Limited; Phelps Johnson, president Dominion Bridge Company, Limited; G. H. Duggan, general manager Dominion Bridge Company, Limited.

The old company was incorporated in 1908, although it existed for some time previous to that, in which time it has built up a considerable business. A good market for the products of the company was developed and in the spring of 1912 it was deemed advisable to place the plant and business in the most advantageous position possible for the handling of its requirements. This resulted in the joint purchase by the Canadian Bridge Company, Limited, of Walkerville and the Dominion Bridge Company, of the control of the organization.

In the fall of last year the plant was thoroughly overhauled and extensions made. Better facilities for fabrication work were introduced by more efficient routing of material, etc. The growth of the business in the eastern provinces and the development of the plant under the impetus of the changes made has been very marked.

DURABILITY OF TIES.

The average life of untreated ties as reported by the steam roads is as follows: Cedar, 9 years; tamarack, 8 years; hemlock, 7 years; Douglas fir, 7 years; jack pine, 6 years; spruce, 6 years. As recent statistics bear evidence, cedar is the species pincipally used, because of its durability, but the supply of cedar is rapidly becoming exhausted. Unless preservative treatment of ties is introduced, the short-lived species will have to be used untreated, which, on account of the necessary frequent renewal, will increase the cost of mileage maintenance. If treated ties were used, which would cost 30 cents extra per tie for creosoting and equipping with tie-plates, the inferior species, which are very plentiful and cheap in Canada, could be used with economy. With such a treatment, these woods would last at least fifteen years, and if protected from wear would probably last much longer, and would effect a very considerable saving.

COAST TO COAST.

Fort William, Ont.—The city of Fort William will take over their end of the electric street railway this coming fall. Heretofore the city of Port Arthur controlled the street railway under a joint board, made up of representatives from both cities. Formal steps have already been made in connection with the operation and interchange service between the two cities.

Toronto, Ont.—Superintendent Bennett, of the Colonization Roads Department, has arrived at the Parliament Buildings after an inspection of the districts recently visited by forest fires. The damage to bridges, he said, was very slight. In the Sudbury district a $25,000 colonization road nine miles in length was completed last week. The colonization road work had not been seriously delayed by the fires, and the extent of territory benefited this season was likely to make a new record.

Ottawa, Ont.—A great improvement has been made to the Richmond Road between the city limits and Westboro. Employees of the Bytown and Ottawa Road Company have covered the road with tarvia. As it is now almost a dustless road, it is certainly a great improvement, and one that is much appreciated by those residents living along the way. For some time the residents of Westboro and all along the Richmond Road have been urging the road corporation to take action in the matter, and at one time they suggested that the road through the village should be treated at the expense of private parties. It is understood that the road company intends to cover the road with tarvia for several miles west of Westboro. This will also meet with the approval of farmers in that locality.

Victoria, B.C.—The city officials are paying about $8,000 a month to the Esquimalt Waterworks Company for the purchase of water from Goldstream, judged on the basis of last month. It is intimated by a prominent city official that the yearly cost will run to $80,000. It is frequently stated that the city is making a profit by buying water at half its retail cost, to sell again to consumers, the observation being based on the fact that the Esquimalt Company is selling five million gallons of water per day at six cents a thousand gallons. However, of that amount at least 30 per cent. never is retailed to consumers, the loss in the mains, evaporation at the reservoir, water for city services, and the amount lost in other ways absorbing the difference. Besides, the city has to maintain a distributing service for its consumers. Those in touch with the matter expect that the profit and loss account on this purchase will not show a large margin for the city when the whole information is tabulated for the consideration of the council.

Toronto, Ont.—Sir William Mackenzie, president of the Canadian Northern Railway, has secured the money necessary for the fulfilment of the Canadian Northern Railway Pacific Coast terminal plans, and they are to be proceeded with without delay. In a recent interview Sir William stated that, of the capital he had secured in London—an issue of $2,000,000 of 4½ per cent. terminal bonds, and an issue of $7,500,000 of five per cent. five-year notes—a large portion would be immediately used for western terminal development and the remainder for the building of an extension of the Canadian Northern Railway lines in Western Canada. Included in the Canadian Northern Railway Pacific Coast plans are large yards and shops to be erected at Port Mann; terminal stations, etc., at Victoria and New Westminster, and at the city of Vancouver a project which involves an expenditure of $10,000,000, and which will take five years to carry out. In consideration of the conveyance to the railway by the citizens of Vancouver of what is known as False Creek, the Canadian Northern Railway are building the main Pacific terminals thereon, including a big passenger depot at a cost of $1,500,000; the erection of a modern hotel, and the absolute reclamation of False Creek. The plans further called for making the railway's own entrance into Vancouver by way of a tunnel from New Westminster, the construction of which will cost in the neighborhood of $4,000,000.

Ottawa, Ont.—The Commission of Conservation, under the chairmanship of Hon. Clifford Sifton, has issued an exhaustive and carefully prepared report on the general question as to the giving of power rights on the St. Lawrence River to private corporations, with special reference to the application pending before the United States Congress from the Long Sault Development Company for rights to dam the St. Lawrence at the Long Sault Rapids, near Cornwall. The enormous importance of the power franchises, involving the whole industrial development of Eastern Ontario, Western Quebec and the bordering American States, is fully pointed out in the preface to the report, and the logical conclusion is reached from a study of all the conditions that the plain duty of the Federal Government is to maintain public ownership and control of all the power rights on the river absolutely unimpaired. The Commission strongly urges that public interests in power development on the St. Lawrence should be conserved for all time, and that the persistent efforts of the merger company to secure monopoly rights should be firmly resisted.

Toronto, Ont.—It is rumored in the city that the farmers in the County of York are concluding that the good roads provided by the Commission do not meet the requirements of vehicular traffic. Not only is it stated that the good roads so far supplied are not so constructed as to stand the wear and tear of traffic, but macadam roads are being declared a failure. There are many who have reached a conviction that the only solution of the good roads problem is to construct asphalt pavements, the same as in the city. Such is the condition of public sentiment upon the results shown by the Commission that a reorganization of the good roads movement in the near future is likely to be demanded.

Toronto, Ont.—The Toronto Board of Trade is preparing for an active year in civic improvement and the general development of Ontario and Canada, and will in October resume the publication of The Board of Trade News, the official publication of the organization, which is not issued during the months of August and September. The members and officials of the organization are naturally proud of the things accomplished in the past, and point with pride to the creation of the Board of Railway Commissioners, the Harbor Commission, the work on the new Welland Canal, the agreement for a railroad viaduct on the water front, and the initiation of the movement for good roads with an appropriation to date of $600,000. The scope of the future work of the Board of Trade may be understood from the appointment of special committees to give attention to the subjects named, viz., harbor and Welland Canal, railway and transportation, legislation and education, good roads, civic and social service, Ontario development, express rates and parcel post, viaduct, publicity, Federal square, foreign trade, membership and conference committee of one hundred. The organization was incorporated in 1845, and now has a membership of 2,800.

Toronto, Ont.—Toronto will have the finest freight terminals in the world before this time next year. The Canadian Pacific Railway has just completed plans for additional buildings to be erected at the corner of King and Simcoe Streets, on the old Government House site, and the Grand Trunk Railway also is planning the erection of more buildings at the corner of Wellington and Simcoe Streets. City Architect Price and the division engineers of the Canadian Pacific Railway declare that the Toronto freight terminals will

be the most modern anywhere. The large new building which the Canadian Pacific Railway will erect at King and Simcoe Streets will cost over half a million dollars. It will be used by the freight department and the Dominion Express Company, which will leave the Union Station altogether. Following is a partial list of the works the Canadian Pacific will carry out in connection with its new freight terminals: Solid brick and steel warehouse, fronting on King Street, 500 by 75 feet, to be used by the freight department and the Dominion Express Company, cost $500,000. Freight house for inbound freight, 900 by 50 feet; freight house for outbound freight, 900 by 50 feet; covered transfer platform, 900 by 50 feet; offices on Simcoe Street connecting both freight houses, size 40 by 185 feet. All buildings will be of solid brick and steel construction, and the total cost of erecting them is estimated at $1,200,000. This does not include the cost of track-work, paving, real estate, legal and other general expenses. The real estate alone cost over $2,000,000; a retaining wall to support the south side of Front Street will cost $49,000; it will cost $43,000 to pave roadways, and the track-work, grading and incidentals will cost $132,000. There will be fifteen railway tracks in connection with the Canadian Pacific Railway terminals and three granite-block-paved team roads with alternate tracks.

Victoria, B.C.—Costing $4,000,000, and unquestionably to be the largest shipbuilding drydock and ship-repairing plant in Canada, the scheme of the Amalgamated Engineering Company for North Vancouver has been approved by Hon. R. Rogers, Minister of Public Works. Work will be started as soon as the necessary formalities are arranged with the Government. The plant will be situated in D. L. 265, and will include a floating drydock, a shipbuilding plant and ship-repairing works of the most modern type. The immense basin will give a depth of thirty feet at low tide. The floating dock will have a lifting capacity of 20,000 tons, which will provide a wide margin over the present requirements of shipping in Burrard Inlet. A second dock will be built to the west of the basin capable of accommodating smaller vessels. Building berths will also be erected. Four in number, two will be 750 feet long and 100 feet wide, and two will be 350 feet long and 75 feet wide. Shops will be constructed in connection with the works and with the railway facilities of the North Shore. Electric cranes and the latest machinery will be the features of these. Construction of the plant will require three years. When in full working order it is expected to give employment to an average of 2,000 men. Plans are now being hurried forward, and, when ready, will be forwarded to the Dominion Government so that the necessary Order-in-Council may be passed. Mr. C. J. V. Spratt, of Victoria, is managing-director of the company, which includes Col. Sir Henry Pellatt, Col. Sir John M. Gibson, Lieutenant-Governor of Ontario; Mr. D. B. Hanna, and Mr. E. J. Palmerm, of the Victoria Lumber and Manufacturing Company, Chemainus. Also, there is an advisory board of directors—men of high standing in Great Britain. The site, which was purchased from the Lonsdale estate, covers an area of eighty acres—which is quite sufficient for the establishment of a great and flourishing industry. The original idea was to invest $2,500,000 in the scheme, but after further consideration it was felt that a more comprehensive plant was needed, and enlargement was accordingly effected. The company acquired the property on especially favorable terms on the understanding that they would complete the construction in a given time, and that they would give employment to a certain number of men within a specified period.

Montreal, Que.—An appropriation of $1,500 to cover the expenses of a specially qualified man to report on the whole plan of municipal ferry-boats running to St. Helen's Island is recommended to Council by the Controllers. They favor municipal ferries rather than a renewal of the present contract, which expires on May 1st, 1915. There may be some opposition to this recommendation as there is standing in abeyance just now a scheme for another report of a somewhat similar character. The Council approved of the idea of having a report from two engineers, appointed by the city and Harbor Board, respectively, on the suitability of the Island for an exhibition and the possibilities in the way of developing sufficient means of access. The city has appointed a man but the Harbor Board has not as yet. The report now desired by the Board of Control is to be on the kind of boats required, their probable cost, best places for docks, and probable cost of the whole scheme.

Montreal, Que.—The corporation of Montreal is employing 10,000 men, outside of the permanent staff. More than half of these are engaged in laying concrete and asphalt pavements and sidewalks. The weekly payroll is more than $100,000. The work commenced early in the spring and will be continued until the snow comes. The demand for unskilled labor has long since far exceeded the native supply, and the importation of foreign hands is steadily increasing. The Italians and other Southern Europeans who do this kind of work were formerly of a nomadic character, but employment has been so steady and there is so much in sight that they are becoming permanent residents. This season a large number of Russians have been added to the labor population of the city and suburbs.

New Westminster, B.C.—Mr. F. J. McKenzie, M.P.P. for Delta, took a seventy miles trip over Langley and Surrey Roads recently, and found that the work was being speeded by both government and municipal employees in order to put as much of the road improvement through as possible before the rainy season begins September usually sees the end of the season, but there is no question that the roads on the south side of the Fraser will be in much better condition for traffic this winter than they were last. A great amount of road grading has been done, which is now being ballasted, and a start has been made with rocking the road between Murrayville and Langley Prairie. This is the beginning of rock work in Langley Prairie, and in future rocking will supplant gravel in that municipality. The route taken by Mr. McKenzie was through Port Mann, Port Kells, Jericho, Clayton and Colebrook, and returning by the Scott Road and the hill there, about which so much complaint has been made, is now in good condition.

Vancouver, B.C.—The greatly improved roads of North Vancouver are beginning to exert a great attraction for Vancouver automobilists. Most striking testimony of this is the fact that fines imposed on motor car owners and drivers by the North Vancouver district police courts are far greater than they were two years ago. The latest move in the good roads project across the Inlet was the application by the Vancouver Automobile Club recently to the District Council asking that the remaining two miles of Keith Road to Deep Cove be surfaced by the municipality. Mr. Ford, the secretary, in his communication, showed the advantages in increase of trade an increase in automobile traffic would entail. It was said that the cost of the work would be proportionately trifling. The Council replied that it had the matter under consideration for some time, but that finances did not permit the letting of the contract. When the revenues increased, it would be possible to take up the project again. In the meantime the letter was referred to the Board of Works. Automobilists from Vancouver have opportunities for three splendid tours in North Vancouver. By far the best, and the one most frequently travelled is the Capilano Road. The Lynn Valley Road has been macadamized, and presents a good surface for automobiling from the North Vancouver Ferries entrance to the Rice Lake intake. The Dundarave Road contains less hills, and furnishes a beautiful view. Part of

this thoroughfare runs through West Vancouver, where the "boulevard" is the pride of the residents. All three routes run through pleasant stretches of woods and near wonderful stretches of water. The West Vancouver highway will, it is expected, some time be a business street throughout the greater part of its length. In the three municipalities the greatest expenditure is for this road.

Montreal, Que.—In a report to the Harbor Commission, F. N. Cowie, engineer of the Commission, reports a serious state of affairs in regard to the pumping station for sewage being erected near the Place Royale. The site selected adjoins the Sailors' Institute and the Birmingham Building. It was necessary for the contractor to go down a considerable distance for the foundations. For fourteen feet good soil was found, but below that clay and quicksand, very wet, has been met with. Mr. Cowie advises the Harbor Commission to assume no responsibility whatever for the work, as the city of Montreal made the selection, the station being needed for the diversion of sewage from the Elgin basin. The work is being done at the joint expense of City and Harbor Commission. Mr. Cowie declares that the Birmingham Building will have to be taken down, as the walls are in a state of collapse, and the walls of the Sailors' Institute are none too safe. The excavation, states Mr. Cowie, is in a deplorable condition. The timbering has collapsed and the lower portion of the ground is caving in. The depth of the excavation is held responsible by Mr. Cowie for the condition of the Birmingham Building and the Sailors' Institute.

Prince Albert, Sask.—An exhaustive report on the power situation by F. A. Creighton, power manager, which has been in the hands of the aldermen for some time, was read at the last meeting of the city council, at which P. H. Mitchell, the consulting engineer, was present, and made a number of explanations on various points. The estimated cost of completion of the scheme on the basis of a 4,000 horse-power capacity is $1,700,000, and of this sum $771,111 was spent up to June 30th. One of the most important points in the report was in regard to the flow of water at La Colle Falls during the dry season of the year. According to a gauging taken last year, the only one available, that flow is only 1,500 second feet during January, February and March, and with such a flow only 3,360 horse-power could be generated. Mr. Mitchell emphasized the handicap they had from the lack of sufficient and reliable data on those gaugings, and it was decided to petition the Dominion Government to make arrangements twice a week from November till May.

PERSONAL

M. B. WATSON, B.A.Sc., has been appointed Assistant Engineer to the Ontario Highway Commissioners.

GEO. H. POWER, of Chipman and Power, Consulting Civil Engineers, is returning this week to take charge of the Winnipeg office, after spending several months in Toronto.

J. H. BILLINGS, B.A.Sc., has accepted a position in the Department of Mechanical Engineering of the University of Missouri, Columbia, Mo., as instructor in thermodynamics.

GEO. CONDON has accepted an appointment from the National Steel Car Company, Ltd., of Hamilton, Ont., to represent them in Montreal. The new offices are in the Shaughnessy Building.

V. A. E. GOAD, B.A.Sc., has gone to Montreal where he will take permanent charge of the Montreal interests of the Chas. E. Goad Company. Mr. Goad has been associated with the main office in Toronto for the past three years.

ISHAM RANDOLPH, C.E., of Chicago, announces that he has removed his offices to Suite 1807 Commercial National Bank Building, north-east corner of Adams and Clark Streets, where he will continue his practice as consulting engineer.

F. D. MANNING has been appointed Canadian sales manager for the Continental Car Equipment Company, Inc., of New York City and Louisville, Ky., manufacturers of dump cars. Mr. Manning will have his offices in the C.P.R. Building, Toronto.

WM. C. WILLARD has been appointed Assistant Professor of Railway Engineering at McGill University, succeeding Professor Smart, resigned. Mr. Willard is a graduate of Lehigh University, an associate member of the American Society of Civil Engineers and a member of the American Railway Engineering Association. He leaves the position of Assistant Civil Engineer, Panama-Pacific International Exposition, San Francisco, California, to come to Montreal. Among other positions of importance held by Mr. Willard are those of Instructor in Civil Engineering and Director of the Summer School of Surveying, University of California; Assistant Engineer, construction department, Southern Pacific Railway; Professor of Railway and Highway Engineering, State College of Washington, and Assistant City Engineer, Oakland, California.

COMING MEETINGS.

THE ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Sixth General Annual Assembly will be held at Calgary, Alberta, September 15th and 16th. President, J. H. G. Russell, Winnipeg, Man.; Hon. Secretary, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

NATIONAL PAVING BRICK MANUFACTURERS' ASSOCIATION.—Tenth Annual Meeting will be held at Cleveland, Ohio, September 17th and 18th. Secretary, W. P. Blair, 824 Engineers' Building, Cleveland, Ohio.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Third Annual Meeting in Regina, September 18th, 19th and 20th. General Secretary, Major Lorne Drum, Ottawa; Local Secretary, R. H. Murray, C.E., Regina.

ILLUMINATING ENGINEERING SOCIETY.—Annual Convention to be held at Pittsburg, Pa., September 22nd to the 26th. Secretary, I. D. Israel, 29 West 39th Street, New York City.

AMERICAN ROAD CONGRESS.—Annual Session will be held in Detroit, Michigan, from September 29th to October 4th. Secretary, J. E. Pennybacker, Colorado Building, Washington, D.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—Twentieth Annual Meeting to be held in Wilmington, Del., October 7th to 10th. Secretary, A. Prescott Folwell, 15 Union Square, New York.

UNITED STATES GOOD ROADS ASSOCIATION.—Convention will be held at St. Louis, Mo., November 10th to 15th. Secretary, J. A. Rountree, L021 Brown-Marx Building, Birmingham, Ala.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

20117—August 16—Authorizing the C.N.R. to cross with its lines and tracks the spur to the Manitoba and Saskatchewan Coal Co., and to cross and join with the spur to the Western Dom. Collieries, in the S.E. ¼ of Section 19, Tp. 2, Rge. 6, W. 2 M., Sask.

20118—August 18—Further extending until March 1st, 1914, the time for the use of the connection of the C.N.O.R.'s tracks with the tracks of the C.P.R. at Meadowside.

20119—August 14—Authorizing the G.T.P. Branch Lines Company to construct its railway across Eighteenth Avenue East, Strathcona Avenue, Laurier Avenue, Rupert Avenue, Connaught Avenue, 1st Avenue West, 4th Avenue West, Sixth Avenue West, and 8th Avenue West.

20120—August 15—Approving revised location of G.T.P.'s main line, Yellowhead Pass West, mileage 43.24 to mileage 49.26, District of Cariboo, B.C.

20121—August 15—Authorizing the G.T.P. to construct, maintain and operate branch line of railway, or industrial spur for the town of Tofield, Sec. 36, Tp. 50, Rge. 19, W. 4 M., Dist. of North Alberta, Prov. of Alta.

20122—August 19—Authorizing the G.T.P. to construct highway across its main line of railway in Lot 14, Parish of Headingly, mileage 13.21, Mun. of Assiniboia, Dist. of Winnipeg, Prov. of Man.

20123—August 15—Authorizing the C.P.R. to operate their trains over the crossing at Delson Jct., without their first being brought to a stop.

20124—August 14—Approving proposed changes in the location of the G.T.R. Co.'s tracks leading to its coach yard in the vicinity of St. Marguerite St., St. Henri, Montreal.

20125—August 18—Authorizing the G.T.P. Branch Lines Company to construct its line of railway across and divert the highway in the N.W. ¼ of Sec. 12, Tp. 11, Rge. 17, W 1st M, at mileage 10.4, Rural Mun. of Elton, Dist. of Brandon, Man.

20126—August 16—Authorizing the G.T.P. Branch Lines Company to construct, maintain, and operate the branch line of railway or spur, turning out from its Yorkton Branch to the Power House in the town of Yorkton, Sask.

20127—August 18—Authorizing the G.T.R. to construct, maintain and operate branch line of railway, or siding, Parish of St. Anne de Bellevue, Co. Jacques Cartier, Que., commencing at a point on its railway east of the station, known as St. Anne de Bellevue, thence extending in a westerly direction to the premises of the MacDonald Agricultural College, on Lot 302.

20128—August 19—Authorizing the Lake Erie and Northern Railway Company to construct its tracks under the tracks of the G.T.R. by means of an undercrossing, at station 1192+42.9, near the town of Simcoe.

20129—August 14—Authorizing the Lake Erie and Northern Railway Company to construct its railway across Townsend Street, McCall Street, Wilson Street, and Victoria Street in the town of Simcoe, Ontario.

20130—August 14—Granting leave to the Lake Erie and Northern Railway Company to raise the tracks of the Grand Valley Railway Company two feet to meet the elevation of the L.E. & N. Railway at the County Line between the Co. of Brant and Co. of Waterloo at station 868+97.

20131—August 16—Authorizing the Edmonton, Dunvegan and British Columbia Railway Co. to construct its railway across the highway between Secs. 36 and 1, Tps. 68-69, Rge. 2, W. 5 M., Alta

20132—August 18—Approving revised location of the E.D. & B.C. railway from mileage 112.33, through Twps. 68-69, Rge. 2, W. 5 M., Alta.

20133—August 15—Ordering the C.N.O.R. to restore the former connection between Napanee and Tamworth, Ont.

20134—August 16—Authorizing the T.H. & B. Railway to divert highway between Lot 14, 10th Con., and Lot 14, 11th Con., Tp. of Pelham; to divert highway between Lot 1, 13th Con. and Lot 1, 14th Con., Tp. Pelham; to divert highway between Lot 9, 11th Con. and Lot 9, 12th Con., Tp. Pelham; to divert highway between lot 5, 12th Con. and lot 5, 13th Con. Tp. Pelham.

20135—August 15—Dismissing application of the Empire Limestone Company, Limited, for authority to construct a tunnel under the right-of-way belonging to Carroll Bros., on Lot 5, Con. 1, Twp. of Huberstone, Ont.

20136—August 11—Refusing application of the Dominion Sugar Company for a readjustment of the rates on sugar, in carload quantities, from Wallaceburg to Toronto and from Wallaceburg to Hamilton, over the lines of the C.P., G.T., Pere Marquette, and Chatham, Wallaceburg and Lake Erie Railway Companies.

20137—August 21—Authorizing the V. V. & E. Ry. & Nav. Co. to construct, maintain, and operate spur to the Kilgard Fire Clay Co.'s works at Kilgard, B.C.

20138—August 19—Authorizing the New York Central Ry. Co. to remove station called Primeau, Que., from its present location to a point immediately to the east of the G.T.R. Co.'s line at the Kanawaki Golf Club grounds.

20139—August 19—Ordering the C.N.Q. Ry. to construct a suitable passenger station at Arundel, Que.

20140—August 19—Ordering the C.P.R. to install an improved type of illuminated electric bell at the Main Street crossing in Milverton, Ont., and to thereafter maintain the said bell at its own expense.

20141—August 20—Authorizing the G.T.P. to carry traffic over that portion of its railway in British Columbia between Tete Jaune, mileage 1095.3 and the second crossing of the Fraser River, mileage 1189.0, a distance of 93.7 miles.

20142—August 15—Approving revised location of portion of the C.P.R. from mileage 37.35 at a point in Sec. 14, Twp. 23, Rge. 18, W. 5 M., thence in a southeasterly direction to a point in Lot 11114, East Kootenay District, B.C., at mileage 57.18, on the C.P.R.'s Kootenay Central Branch.

20143—August 19—Approving locations of the Esquimalt and Nanaimo Ry. Co.'s stations, Union Bay and Courtenay, British Columbia.

20144—August 20—Approving revised location of the G.T.P. Branch Lines Co.'s Tofield-Calgary Branch through the North Half of Section 10, Twp. 42, Rge. 21, W. 4 M., Alta.

20145—August 20—Approving revised location of G.T.P. Branch Lines Co.'s Tofield-Calgary Branch through Sec. 21, Twp. 29, Rge. 24, W. 4 M., Alta.

20146—August 20—Authorizing C.P.R. to construct bridge No. 0.16 for double tracking, over Yamaska River, near Brigham Jct., Que.

20147—August 22—Approving proposed location of shelter on the West Half of Lot 3, Con. 2, Twp. Eldon, Prov. Ont.

20148—August 20—Authorizing C.P.R. to construct Bridge No. 88.6, and an additional track at mileage 88.73 of its Toronto Subdivision, Ont. Div., across and over the tracks of the G.T.R.

20149—August 20—Approving revised location of C.P.R.'s Bassano Easterly Branch, from a point in Sec. 5, Twp. 22, Rge. 3, W. 4 M., at mileage 98.72, thence in an easterly direction to a point in Sec. 10, Twp. 23, Rge. 1, W. 4 M., at mileage 115.59; and authorizing the C.P.R. to construct its tracks (Bassano Easterly Branch) across certain highways in the Province of Alberta.

20150—August 20—Authorizing C.P.R. to construct bridge No. 37.9, Toronto Subdivision, Ontario Division of its railway, Ontario, near Bethany Jct.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

▲—Denotes an item regarding work advertised in *The Canadian Engineer.*
+—Denotes contract awarded. The names of successful contractors are set in CAPITALS.

RAILWAYS—STEAM AND ELECTRIC.

+—Brantford, Ont.—The Lake Erie and Northern Railway Company has awarded MESSRS. WRIGHT, HAZZARD & COHEN, Buffalo, the contract for the raising of the Lorne bridge. This job is one of the most important in the construction of the entire line, as it was part of this route which required a special session of the Dominion Railway Board. The contract price is about $15,000.

Calgary, Alta.—A number of extensions of the street car system which the city had planned earlier in the season to make this year, but which were abandoned when at one time it appeared that money was going to be scarce, have been restored to the programme of improvements for this season since the million dollar loan came through. There are seven such proposed extensions running from half to three-quarters of a mile each, and aggregating about four miles, which it has now been decided to proceed with.

Chatham, Ont.—The Canadian Northern Railway has secured control of the Chatham, Wallaceburg and Lake Erie Electric Railroad. Proposed extensions will be undertaken shortly.

Kingston, Ont.—The Canadian Northern Railway have completed the work of grading between Napanee and Sydenham, and have commenced laying their rails. The company expect to start the service between the two towns before winter.

Montreal, Que.—The contract between the Montreal and Southern and Counties Railway Company and the city of Montreal has been completed at last, and was laid before Mayor Lavallee recently for signature. His Worship will await a report from City Attorney Laurendeau as to the validity of the contract before signing it.

Moose Jaw, Sask.—The Canadian Northern Railway and Grand Trunk Pacific are both busily engaged on their construction work in this city. The Grand Trunk Pacific are putting ballast on their right-of-way through the city, and the Canadian Northern Railway are working on their bridges over the river and completing the grade work between the various sections.

Nelson, B.C.—It is officially announced that arrangements are about completed for ordering four electric locomotives at an approximate cost of $75,000 each, to be used on the Castlegar to Rossland line of the Canadian Pacific Railway, which is to be electrified shortly. Though construction work has not yet actually started on the electrification of the line, preliminary arrangements are being made, and work will be commenced in a short time. Already the West Kootenay Power and Light Company has made arrangements to increase the capacity of its power plant at Bonnington Falls, and the necessary machinery is being ordered. Nine thousand horse-power is being added to the plant. The completion of the electrification of this route is expected to overcome the difficulties now experienced on the heavy grades on the Rossland hill, and a noticeable reduction in the time of the run from Castlegar to Rossland.

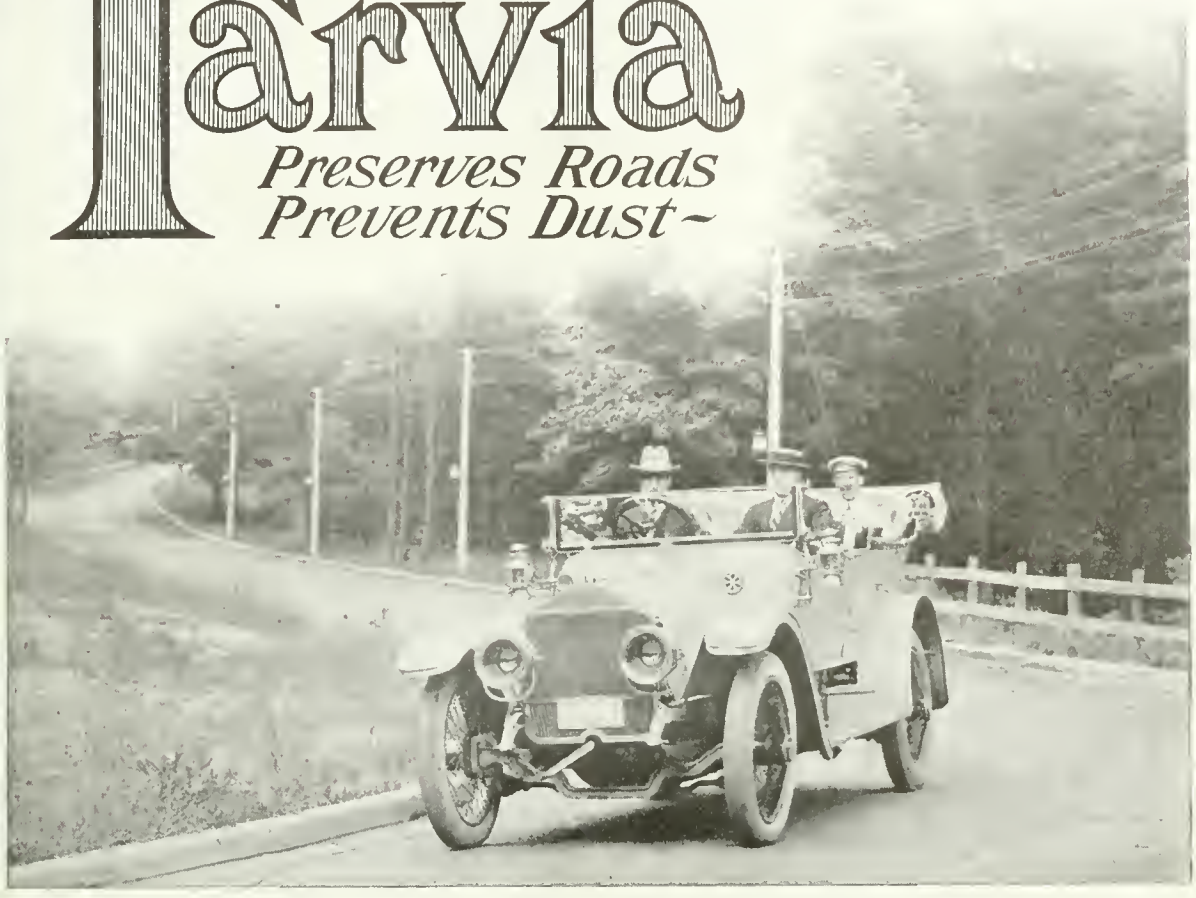
Toronto, Ont.—Work on the Canadian Pacific Railway east of Toronto is proceeding rapidly. The lake front line, which leaves the main track at Agincourt, is nearly completed as far as Bowmanville. The work of double-tracking between Agincourt and Toronto was begun during the month, and excavations are being made for two large bridges over the Don and West Don.

Toronto, Ont.—According to H. R. Safford, of Montreal, chief engineer of the Grand Trunk Railway, there is no doubt about a start being made on the construction of Toronto's new Union Station next spring. Mr. Safford passed through Toronto recently on his return to Montreal after a western inspection trip. "We are working hard on the Toronto station plans, and they will be ready in plenty of time to allow a commencement to be made by the spring," he said.

+—Victoria, B.C.—The Canadian Northern Railway has awarded a joint contract to MR. A. J. McDONALD and MESSRS. NETTLETON, BRUCE, ELSBACK COMPANY for the construction of the line of railway from Patricia Bay to the entrance to the Songhees reserve terminals at Victoria, which will complete the Island link in the rail and ferry service between Vancouver and the provincial capital. The distance covered by the work is about twenty miles, from Patricia Bay, formerly known as Union Bay, on the north.

Tarvia

Preserves Roads
Prevents Dust~



Overcomes Washing on a Heavy Grade

The above cut shows Russell Hill Road in Toronto, a water-bound macadam road with a heavy grade. Formerly great damage was done to the surface of this roadway by washing, and incessant repairs were required to keep it in satisfactory condition.

In June, 1912, a coat of "Tarvia B", at the rate of one-third gallon per yard, was applied. The Tarvia penetrated into the road surface and hardened, thus reinforcing the natural binder, cementing the surface together and making the surface shed water like the proverbial duck's back. The torrents which formerly had destroyed the surface now ran off harmlessly, and the road showed no further signs of washing. In addition, the surface remained practically dustless and gave superior resistance to automobile traffic.

Water torn roads are as unnecessary in these days as dusty roads. The up-to-date engineer knows how to prevent water damage and dust by the use of a bituminous binder. The best and most economical binder is Tarvia, a coal tar product especially prepared for road work. There are three kinds of Tarvia:—"Tarvia X," very dense, for the large voids of new construction; "Tarvia A," for thorough resurfacing work; "Tarvia B," which was used in the above contract, for dust prevention.

In all cases the function of Tarvia is the same—to seal the surface against water, to give it an element of plasticity enabling it to resist automobile traffic, and to bind the stone together to prevent internal movement and attrition by traffic. Booklets on request. Address our nearest office.

THE PATERSON MANUFACTURING COMPANY, LIMITED
MONTREAL TORONTO WINNIPEG VANCOUVER

THE CARRITTE-PATERSON MANUFACTURING CO., LIMITED
ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

westerly shore of the Saanich peninsula to a junction with the main line of the railway. The same contract also covers the work from mile 4.7, outside Victoria, through the city and up to the approach to the terminals on the Songhees reserve. The construction on these two different portions will commence at once and will be carried on with the greatest speed consistent with good work.

Victoria, B.C.—Grading of the Canadian Northern Pacific Railway to mile 52 from the present terminus at mile 4.7 should be ready in about another month, and the whole of the work of grading up to mile 100 is well in hand. The activity along Sooke Lake has been particularly noticeable this summer, as has also that on the contracts of Moore and Pethick further north. The engineers are already preparing for the important steel work which has to be undertaken for river and ravine crossings, notably the steel viaduct over the Koksillah River, and the steel bridge over the Cowichan River, where facilities will be required to handle the material expeditiously in order that the work can go forward satisfactorily when it is commenced. A wharf has been built at Patricia Bay for the purpose of handling material. The plans for the crossing of Selkirk water have also been lodged with the proper authorities.

BRIDGES, ROADS AND PAVEMENTS.

+—Brantford, Ont.—The township council has awarded the ROYAL ARTIFICIAL PAVING COMPANY, Guelph, the contract for the construction of 38,200 square feet of sidewalk on Hamilton Road. The contract price is 12½ cents per square foot.

Calgary, Alta.—The City Commissioners will recommend to the Council that the action of the Council whereby the Mineral Rubber Company was awarded additional paving on Sifton Boulevard, be rescinded and in lieu thereof, the company be given a contract for paving on other streets where it had been decided to lay pavement since the assurance that more funds for public improvements was received. The new proposal is to give the Mineral Rubber Company a contract to pave Center Avenue from Tenth Street West to Eleventh Street A; Seventh Street West from Second to Fourth Avenue north-west; Second Avenue from Tenth Street west to connect with the present pavement near Ninth A Street north-west.

▲—Cayuga, Ont.—Tenders will be received up till the 16th of September, 1913, for the construction of 26½ miles of stone macadam road. Plans and specifications may be obtained from T. A. Snyder, County Clerk.

Haileybury, Ont.—Work on the Lake Shore Road section of the Cobalt-New Liskeard trunk road was commenced recently. The Main Street work has been completed except for the top dressing of macadam, and it is not the intention to start work on Ferguson Avenue, until everything is in readiness to complete the work in short order. On the Lake Shore Road, the street is being levelled preparatory to the gravelling after which the road will be stoned and tolled. It is altogether likely that the rock for this work and all that work from the town to New Liskeard will be brought in over the spur line.

+—Kingston, Ont.—The City Council has awarded the ONTARIO ASPHALT BLOCK COMPANY, Windsor, the contract for the additional paving of city streets. The contract price is $2.75 per square yard.

Lindsay, Ont.—The town council has received a tender from Messrs. Nasmith and Pogue for the construction of granolithic sidewalks. The contract price is 14 cents per square foot.

+—Montreal, Que.—The Dominion Government has awarded the HAMILTON BRIDGE COMPANY the contract for the construction of a steel swing bridge over the Chambly Canal at Garocques crossing. The contract price is $2,450.

Montreal, Que.—By the slow delivery of granite paving blocks, the paving operations on a number of streets have been suspended, according to a report submitted to the Board of Control, by Supt. Barlow, of the roads department. It seems that while the contract awarded last April called for 56,000 square yards of granite blocks, Mr. Barlow declares that up to date, the Elder Ebano Company, which secured the contract, has delivered but 14,752 square yards. This quantity, states Mr. Barlow, is by no means sufficient to meet requirements and in consequence, the paving operations on a number of streets have been suspended.

+—Ottawa, Ont.—The Dominion Government has awarded the HAMILTON BRIDGE COMPANY the contract for the construction of the double track railway swing bridge of the Welland Canal. The contract price is $65,800.

+—Saskatoon, Sask.—The city council has awarded MESSRS. LONERGAN AND HANSFORD the contract for fixing Long Hill. The contract price is $15,000, and calls for the removal of some 10,000 cubic yards of earth.

+—St. John, N.B.—The City Commissioners have awarded the WARREN BITULITHIC COMPANY the contract for the construction of pavement on King Street. The contract price was $6,170.95. Other firms tendered as follows:—A. R. C. Clark and Son, $7,166.90; B. Mooney and Son, $7,-882.30; Louis Corey, $6,069.85; George and Moses, $6,-751.25. Com. Agar stated that the cost of curbing, $563.90, must be added to the Warren Company's tender, as they had omitted to include this. Their tender would accordingly be $6,733.95, and Louis Corey's tender would be the lowest.

+—St. John, N.B.—The City Commissioners have awarded MICHAEL GEORGE AND MOSES the contract for the construction of pavement on Queen Street. The contract price is $5,709.60. Others firms tendered as follows:—A. R. C. Clark and Son, $6,391.00; B. Mooney and Son, $5,995.90; Warren Bitulithic Company, $5,888.00; Louis Corey, $6,-085.80.

+—Vancouver, B.C.—The Board of Civic Works has awarded the COLUMBIA BITULITHIC COMPANY the contract for the construction of pavements on Burrard Street and Fourth Avenue; from Trafalgar Street to Alma Road, to MESSRS. M. P. COTTON AND COMPANY, with the exception of one block, which it is proposed to award to MESSRS. J. R. NICKSON AND COMPANY. This step was taken in order to ensure an early start on these streets.

Victoria, B.C.—Now that the contract with the Saanich council has been signed the Warren Construction Company, which has the bulk of the contract for the 23 miles of road to be paved, is already making arrangements for assembling material and a start with operations will not long be delayed. The intention is to make a commencement while the weather remains good and to see that the work is planned so that it may be done with due regard to the comfort of vehicular and pedestrian traffic. Considerable interest centres in the road to be undertaken first. While opinion has strongly favored the main Saanich road, the company indicates that this will be a matter for the decision of the reeve and municipal engineer. The probable results of regrading, where it is necessary, will have an effect upon the road which is first to be undertaken, as the material will have to be given time to settle before surfacing. With the Automobile Association locating a country home at the head of the peninsula, the improvement of the trunk road northward out of the city is of much importance.

Walkerville, Ont.—The ratepayers of the town have passed a by-law calling for the expenditure of $8,123 for paving Victoria Road and Walker Road.

LIGHT, HEAT AND POWER.

+—Calgary, Alta.—The City Council has awarded MESSRS. BENNETT AND DEBMAN the contract for the erection of a power sub-station.

Kingston, Ont.—Tenders will be received up till 15th of September, 1913, for supplying and laying 20,000 duct feet of conduit. Plans and specifications may be obtained from Light, Heat, Power and Water Department.

Medicine Hat, Alta.—City Engineer Grimmer is getting in touch with a number of the larger cities in Western Canada and the United States for the purpose of securing data and figures which will assist him in making a report to the City Council on the question of installing an improved street lighting system for Medicine Hat. The question is one, he says, which requires a great deal of careful study and minute investigation, and it is likely to be some little time yet before he is in possession of sufficient data to enable him to make his report and recommendation.

▲—Neepawa, Man.—Tenders will be received up till the 12th of September, 1913, for supplying machinery for additions to the power plant. Plans and specifications may be obtained from *The Canadian Engineer's* offices at Winnipeg.

CONTINUOUS STAVE PIPE

RESERVOIR TANKS

For City and Town Water Systems, Fire Protection, Power Plants, Hydraulic Mining, Irrigation, etc.

Full particulars and estimates furnished.

PACIFIC COAST PIPE COMPANY, LTD.

Factory : 1551 Granville Street, VANCOUVER, B.C. P.O. Box 365.

MANNESMANN STEEL PIPE

FOUR STRONG POINTS

1.—Our tubes can be bent cold on the spot without trouble.

2.—Our tubes can be supplied in lengths up to forty feet, thus effecting a large saving in joints, jointing material and labor.

3.—Leakage is reduced to a minimum, as the joints are far tighter and seventy per cent fewer.

4.—Saving in freight, etc., is considerable, as a steel tube weighs one-third to one-half as much as a cast iron pipe of the same length. And there are other convincing reasons and illustrations in our booklets.

BOOKLETS ON REQUEST

Mannesmann Tube Co., Limited 51 Victoria Square **MONTREAL**

Toronto, and Montreal; W. E. Skinner, Limited, Consulting Engineers, Winnipeg, and J. W. Bradley, secretary-treasurer.

+—Ottawa, Ont.—The Dominion Government has awarded MR. A. G. MARSHALL the contract for the installation of under-ground services in the Parliament buildings. The contract price is $11,995.

Port Hope, Ont.—The Seymour Power Company have been granted a ten-year franchise and will extend their electric power system. The estimated cost is $10,000.

Owen Sound, Ont.—That Owen Sound is destined to take its electric energy for power and lighting purposes from Engenia Falls, on the Beaver River, there seems to be little doubt, in view of the results of the tests for power available there at low-water mark this summer, a season that has been the driest for several years. It has been established on the investigation of a practical hydraulic engineer, Mr. T. Hogg, that there is head enough of water at the lowest water mark to generate at least 1,600 horsepower. And this is only at the lowest ebb. Normally there will be a generative potentiality of about 2,500 horsepower, and in the spring, fall and winter there will be over 4,000 horsepower to be drawn upon, and the latter amount would be constant for twelve months of the year.

▲—Regina, Sask.—Tenders will be received up till the 1st of October, 1913, for supplying equipment for powerhouse. Plans and specifications may be obtained from E. W. Bull, Superintendent of Light and Power Commission.

▲—Regina, Sask.—Tenders will be received up till the 25th of October, 1913, for supplying equipment for powerhouse. Specifications may be obtained from E. W. Bull, Superintendent of Light, Heat and Power Department.

Saskatoon, Sask.—Following a conference between J. T. Johnstone hydraulic engineer for the Dominion Government and the City Commissioners, it is understood that the government will be requested to send experts to Saskatoon to investigate one or more sites from which it is considered cheap power could be obtained. The site most favored by Mr. Johnstone, it is understood, is one in the vicinity of the forks.

Souris, Man.—At a meeting of the Town Council recently, it was decided to immediately call for tenders for the electric light plant. A special meeting will likely be held shortly for the purpose of purchasing poles for the immediate construction of the system. It is expected the system will be in operation before Christmas. Already a large number of residences and business places are being wired. A twenty-four hour light and power service will be furnished from the start.

South Vancouver, B.C.—Reports on the construction of a municipal electric lighting plant and a municipal gas plant have been prepared, and when the council convenes, Reeve Kerr will bring them to the attention of the councillors. An electrical engineer of some experience in electric light plants was engaged by the council to report on the feasibility of constructing a plant in the municipality. He also compiled figures of cost, with the intention of informing the council whether it is possible to build a plant in South Vancouver and supply ratepayers with electric light at cheaper rates than those given by the B.C.E.R.

Toronto, Ont.—Tenders will be received up till the 23rd of September, 1913, for supplying fire alarm boxes, ten-circuit protector board, one eight-circuit storage battery board, one motor generator set, three full joker sets, copper wire, etc. Plans and specifications may be obtained from the Board of Control. H. C. Hocken, chairman.

GARBAGE, SEWAGE AND WATER.

Fort William, Ont.—Tenders will be received up till the 15th of September, 1913, for laying water mains on Island No. 2, across Mission River, and hauling cast iron water pipe. Plans and specifications may be obtained from A. McNaughton, city clerk.

+—Edmonton, Alta.—Willis Chipman, Toronto, who has been appointed by the city of Edmonton as consulting engineer, has reported regarding the waterworks situation. In an interview, Mr. Chipman intimated that work would not be started until 1914 on the new filtration plant, for which the contract has been let to the NEW YORK CONTINENTAL JEWELL FILTRATION COMPANY, who were the lowest bidders. Mr. Chipman opposes the plan to "scrap" the existing plant, which was installed by the Roberts Filter Manufacturing Company some years ago. It is not a covered plant and therefore cannot be used in the winter, but aside from this fact Mr. Chipman considers the existing plant quite satisfactory, although not having sufficient capacity to supply all of the city's present requirements. It will likely be used in conjunction with the new plant.

Medicine Hat, Alta.—Recently in testing the western final sedimentation basin, City Engineer Grimmer reports, it was found that the floor of the same cracked and to date the exact cause of this has not been determined. A detailed report of this matter will be submitted to the council at an early date.

Moose Jaw, Sask.—A report has been submitted to the City Council meeting as to the condition of the sewage disposal plant. The report stated that for the first time in the history of the works two motors were in operation this month, and that while they had been shut down for repairs, the operation was approved by the Provincial Inspector. In spite of this Government endorsation as to the merits of the plant in its present capacity, however, the report recommended that the matter of new filtration beds be at once attended to as they were required.

New Glasgow, N.S.—Town Council intends to award a contract for the construction of 6,000 lineal feet of sewer, most 24 in. and 36 in., in diameter, as soon as plans and specifications are finished. D. F. McLeod, town engineer.

North Vancouver, B.C.—Steps to greatly increase the water supply have been taken by the city officials who recently made an extensive inspection trip up Lynn Creek, with the result that two available lakes were found and the water rights on one of them staked on behalf of the municipality. Those who made the trip were:—Mayor Haynes, Aldermen Wheeler, Vance, Williams, Kennedy, City Engineer West and Waterworks Superintendent George Grant. The party secured valuable data for use in planning an increased water supply for future residents of North Vancouver and vicinity.

Ottawa, Ont.—The City Council have received the following tenders in regard to the relaying of the new intake pipe: General Supply Company, $7,952; Campbell Steel and Iron Company, $4,740; Drummond McColl Company, Montreal, $3,450; Loomis, McBain and Williams, Montreal, $6,989. These were referred to City Engineer Currie for report.

South Vancouver, B.C.—In consequence of the criticism of South Vancouver's water supply recently made at ratepayers' meetings and in the press, Water Superintendent Mullett has had samples of water from each of the municipal wells and springs analysed at the government laboratory, Victoria, by Dr. E. Whittaker, the government analyst. Dr. Whittaker reporting on the water from the C.P.R. springs states:—"Both of the above waters are of good quality, being free from animal contamination, and practically free from decomposed vegetable matter. For domestic purposes you could not wish for a better water."

Stamford Township, Ont.—A by-law will be submitted to the ratepayers for the expenditure of $10,000 for waterworks.

Victoria, B.C.—Mr. R. H. Thomson, to whom was referred the plans for the proposed northwestern sewer system, will present his report to the city council shortly. The plans were prepared by City Engineer Rust in conjunction with the engineer of Esquimalt and South Saanich, but the council some time ago decided that Mr. Thomson's expert knowledge should be taken advantage of and his opinion of the proposed scheme as planned, be obtained. Mr. Thomson has been at work on the plans for some time, and his report has been impatiently awaited, as members of the council are anxious that the work, which will give employment to a large number of men, should be started at the earliest possible moment.

▲—Winnipeg, Man.—Tenders will be received up till the 17th of September, 1913, for the construction of 1,150 feet of 24 in. sewer in the municipality of Kildonan. Plans and specifications may be obtained from Mr. F. Hill Parr, Winnipeg and H. Thompson, secretary-treasurer.

+—Winnipeg, Man.—The Board of Control has awarded DRUMMOND McCALL AND COMPANY, Ltd., Montreal, the contract for supplying two 18 in. gate valves, one 30 in. gate valve and three 36 in. gate valves. These will be used for connections to the new 18,000 gallon reservoir.

Winnipeg, Man.—Winnipeg City Council have passed a by-law calling for an expenditure of $13,000,000, for the construction of a water system from Shoal Lake. Voting will take place on this by-law October 1.

Winnipeg, Man.—Secretary Morse, of the Winnipeg Electric Railway denies the report published last week that a contract had been awarded to J. G. White and Company, of New York, for a new power plant on the Winnipeg River. The report is also denied by J. G. White and Company at their New York office. The Winnipeg company is negotiating with the Reese interests for their rights on the Winnipeg River, but no contract has been let as yet for a new plant.

Winnipeg, Man.—Engineer Parr, of Kildonan, was instructed by the council at the meeting recently to prepare plans for a system of waterworks and sewers for the entire municipality. This work will involve the appointment of a consulting engineer.

INDUSTRIAL WORKS.

+—**Chiticamp, N.S.**—The Dominion Government has awarded the NORTHERN DREDGING COMPANY the contract for dredging required here. The contract price is $15,000.

+—**Hants Point, N.S.**—The Dominion Government has awarded the STANDARD CONSTRUCTION COMPANY the contract for the construction of an extension to the wharf. The contract price is $18,685.

+—**Kamloops, B.C.**—The Canadian Pacific Railway has awarded the REID, TODD CONSTRUCTION COMPANY the contract for the construction of a tunnel under the company's tracks here.

Medicine Hat, Alta.—The Gilbert Hunt Company, of Walla Walla, Wash., will locate a large plant here for the manufacture of threshing machines, roller feed mills and farm machinery, according to a statement made by Gilbert Hunt, head of the firm, who arrived here two weeks ago, after an extensive tour of the west.

+—**Montreal, Que.**—The Dominion Government has awarded MESSRS. QUINLAN & ROBERTSON the contract for rebuilding the head of the Grand Pier in the Soulanges Canal. The contract price is $24,238.

Nicolet, Que.—Tenders will be received up till the 15th of September, 1913, for the construction of a jetty. Plans and specifications may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

New Westminster, B.C.—Tenders will be received up till the 15th of September, 1913, for dredging required at the mouth of the Fraser River. Plans and specifications may be obtained from the Department of Public Works, New Westminster. C. C. Worsfield, district engineer.

+—**Ottawa, Ont.**—The Dominion Government has awarded MESSRS. M. J. O'BRIEN and HUGH DOUGHNEY the contract for Section 3 of the new Welland Canal. The contract price was for approximately ten million dollars. There were ten tenders under consideration, including two British and two American firms. Work will be started at once by the successful tenderers, who will make Thorold their headquarters. The contract calls for the completion of the work by April, 1917.

+—**Ottawa, Ont.**—The Dominion Government has awarded the YORK CONSTRUCTION COMPANY, Toronto, the contract for the Severn Division of the Trent Canal. The contract price was $130,278.

Ottawa, Ont.—Having cleared the decks of routine business upon his return from the west, Hon. Robert Rogers has taken up matters which claimed his attention during the trip. These matters include the making and improvement of a number of lake and ocean harbors. He has issued instructions to the engineering corps to draft plans for the greater improvement of the harbors at Port Arthur and Fort William, and at several other harbors on Georgian Bay, as well as at Toronto, Montreal, Halifax and St. John. Immense drydocks will be constructed at Esquimalt, Vancouver and Victoria. The expenditures in connection with the proposed works will total at least $100,000,000, and probably exceed that figure. It is apparently the intention of the Government to make the most of opportunity to develop the trade of Canada, and as the Minister of Public Works, a large portion of the burden of providing the facilities for handling the trade, falls upon Mr. Rogers, who is acting in conjunction with the Minister of Railways and Canals and the Minister of Marine and Fisheries.

Ottawa, Ont.—A hitch has arisen in the tenders for the big harbor works scheme at Toronto, in connection with the mode of making the deposit, and it may be necessary to call for new bids.

Petite Riviere Est., Que.—Tenders will be received up till the 7th of October, 1913, for the construction of a breakwater. Plans and specifications may be obtained from District Engineer J. T. Bertrand, Esq., of Isle Verte, Que., and J. C. Tache, Rimouski, Que., and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

+—**Rainy River, Ont.**—The Dominion Government has awarded Mr. J. T. HORNE the contract for the dredging required here. The contract price is $29,250.

+—**Regina, Sask.**—The City Council has awarded the STEEL FOUNDRIES, LIMITED, the contract for supplying four derail switches for use on the street railway crossings over the steam roads. The contract price is $1,440.00.

+—**Regina, Sask.**—The City Council has awarded Messrs. PEARR BROS. the contract for the reinforcement materials to be used in the walls and foundations of the new power house. The contract price is $5,400.

Regina, Sask.—The City Council passed a by-law recently authorizing the issue of treasury notes to the amount of $249,278.75, the amount of local improvement by-law No. 713. This issue of treasury stock will be put upon the market at once, and will bring the amount of outstanding treasury stock up to about $750,000.

+—**Sault Ste. Marie, Ont.**—The Dominion Government has awarded the SOO DREDGING AND CONSTRUCTION COMPANY the contract for dredging the channel between Goat Island and Little Current to a depth of 22 feet. The contract price is $90,000. This will enable the largest freighters on the lakes to dock at Little Current and it is probable that the dredging is but the first part of a big programme of terminal facilities at that point.

Sparrows Point, Md.—The Maryland Steel Company has awarded the contract for the foundations for a Bessemer mixer and Bessemer mixer building to the RAYMOND CONCRETE PILE COMPANY, New York.

St. Catharines, Ont.—Chief Engineer Weller stated that tenders for No. 2 section of the Welland Ship Canal, extending from the fourth concession line in Grantham township to near Thorold, the northerly boundary of No. 3 section, would be called for within a week. Three weeks later No. 4 section, south of Thorold, with heavy rock excavation, will be ready for the call.

St. Catharines, Ont.—Farmers residing on property expropriated by the Dominion Government, on section number two of the Welland Ship Canal, tenders for which will be called for this week, have been notified to vacate the route land by October 1.

+—**St. John, N.B.**—The council has awarded ROBERT ROBERTS' SONS the contract for the reconstruction of the ferry wharf. The contract price is $9,800.

+—**Swift Current, Sask.**—The AMBURSEN HYDRAULIC CONSTRUCTION COMPANY, Montreal, has been awarded the contract for the construction work on the new dam across the Swift Current River. This dam, when completed, will make a natural reservoir, which will conserve at the lowest estimate, 100,000,000 gallons of water, or sufficient to supply a city having a population of at least 25,000. While the location of the reservoir is such that by dredging the capacity can be increased to almost any amount.

Walkerville, Ont.—The ratepayers of the town have voted favorably on a by-law calling for the expenditure of $16,234 for the construction of an incinerator plant.

+—**Winnipeg, Man.**—The Board of Control has awarded the LINDE CANADIAN REFRIGERATION COMPANY, Montreal, for the contract for supplying a motor-driven refrigerating plant and refrigerator boxes for King Hospital. The contract price is $12,470.

MISCELLANEOUS.

+—**Amherst, N.S.**—The Dominion Government has awarded RHODES CURRY, LIMITED, the contract for the erection of the new armory building. The contract price is $81,100.

+—**Brooklyn, N.Y.**—The RAYMOND CONCRETE PILE COMPANY, of New York, have been awarded the contract for placing concrete piles for the foundations of St.

Why Lose Time "Shopping"

When You Can Buy Anything You Want

"Under One Roof"?

It is just as great a convenience to engineers, contractors and builders to be able to get their supplies from one house as it is to the general public to shop in a large modern department store. The rise of the department store has been the result of economic conditions.

Likewise our business has evolved into a departmental house in the mechanical world in obedience to the same economic law.

This bringing together of a vast number of lines and classifying them according to departments is the kind of combination in industry that makes for efficiency, economy and better service.

Canada's Departmental House for Mechanical Goods

Can supply you with material all the way from nuts to machine tools and oil engines.

Our business is divided into about a dozen different departments, as follows:—Scale Department, Engine Department, Valve and Steam Goods Department, Pump Department, Electrical Department, Transmission Department, Railway and Contractors' Supply Department, Small Tool and Supply Department, Safe and Typewriter Department, and Motor Truck Department.

From time to time we advertise products from the different departments that we think readers of *The Canadian Engineer* are interested in, but you should not by any means infer that those are the only goods we handle.

In this new series of advertisements we wish to drive home the fact that we are literally a "Departmental House for Mechanical Goods."

All you need to do is to make known to us your requirements. Write, telephone, or call.

The Canadian Fairbanks-Morse Co.

LIMITED

"The Departmental House for Mechanical Goods"

ST. JOHN QUEBEC MONTREAL
OTTAWA TORONTO WINNIPEG
SASKATOON CALGARY VANCOUVER

Agatha's R.C. church, corner 7th Avenue and 49th Street, Brooklyn, New York.

Calgary, Alta.—The Armour Packing Company, of Chicago, will erect a plant in this city. The estimated cost is $300,000.

+—Cobalt, Ont.—The Town Council has awarded Mr. F. R. GIBSON the contract for heating, plumbing and wiring of the new town hall.

+—Edmonton, Alta.—MESSRS. G. H. ARCHIBALD AND COMPANY have been awarded the contract for the erection of an office and store building. The contract price is $150,000.

+—Edmonton, Alta.—Messrs. Nicholson and Bain have awarded FYSHE, McNEILL, MARTIN AND TRAINOR, Ltd., Calgary, the contract for the erection of a large warehouse. The contract price is $70,000.

Edmonton, Alta.—Tenders will be received up till the 15th of September, 1913, for supplying coal for the Government buildings. Plans and specifications may be obtained from the Department of Public Works, Edmonton. John Stocks, Deputy Minister.

+—Elmira, Ont.—The Dominion Government has awarded Mr. E. A. BLEAKNEY, Gananoque, the contract for the erection of a post-office. The contract price is $35,000.

Halleybury, Ont.—Tenders will be received up till the 15th of September, 1913, for the erection of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence, Ottawa. Eugene Fiset, Deputy-Minister.

Lambton, Ont.—The county has in consideration additions to court house that will cost approximately $20,000, and has issued bonds for that amount.

+—Le Pas, Man.—The Marconi Telegraph Company has awarded MESSRS. COYLE AND HUGHES, Winnipeg, the contract for the erection of a wireless station. The contract price is $75,000.

London, Ont.—Mr. John Griffin, Toronto, will erect a new play-house in this city. The estimated cost will be $100,000.

Montreal, Que.—The Lachine Council have decided to go on with work on civic improvements which had, for lack of funds, been suspended. The municipal bonds have found a market, and the town is now in a sound financial position. The council gave instructions to have plans drawn up for the extension of the power house and the roofing of the market place. The Mayor was requested to protest against the laying of gas pipes by the Montreal Light, Heat and Power Company, this being done in such a manner, it was stated, as to render likely damage to the corporation water pipes. A permit was granted to the Imperial Oil Company to erect an oil tank in Parc Descarries.

+—Nelson, B.C.—MESSRS. JAS. DANCY AND COMPANY have been awarded the contract for the additions to the Nelson Hotel.

Newport, B.C.—Tenders will be received up till the 26th of September, 1913, for the erection of a police building and lock-up. Plans and specifications may be obtained from the Department of Public Works, Victoria. J. E. Griffith, Public Works Engineer.

+—New Westminster, B.C.—The Dominion Government has awarded MESSRS. SLOAN AND HARRISON the contract for building an addition to the Government's building here. The tender was for $48,000, but the structure will cost altogether about $60,000. The building will be three stories high, with a basement, on a ground space of 32 by 54.

Ottawa, Ont.—Plans are under way for Toronto's new post-office building, which, it is estimated, will cost in the neighborhood of $2,000,000. Tenders for the new custom house will shortly be advertised. The federal square idea has gone by the board owing to the expense involved in expropriation.

+—Ottawa, Ont.—The Dominion Government has awarded the BARNETT McQUEEN COMPANY, Ltd., of Winnipeg and Fort William, the contracts for the internal storage elevators to be erected at Saskatoon and Fort William. Each of the elevators will cost almost one million and Barnett McQueen Company was the lowest of the four tenderers by nearly three hundred dollars. The successful company has just completed the erection of the Government terminal elevator at Port Arthur and the work has met with the approval of the Grain Commission. Contracts call for the completion of the elevators by December 15, 1914, which will be in time to assist in storing the crop next year. As they each have a capacity of three and a half million bushels, this will greatly add to the storage capacity. If necessary, these elevators can be increased to 20,000,000 capacity each.

Ottawa, Ont.—Plans and specifications have been submitted by the Harbor Commission of Montreal to the Marine Department for two new freight sheds at sections 24 and 25 of Montreal Harbor, at a cost of $300,000. Shed No. 24 is to be 275 feet long and 106 feet wide and two stories high, and shed No. 25, 485 feet long and 112 feet wide and also two stories high. The foundation alone will cost $100,000 and will be laid this year, while the general construction will take place in the early spring and will be available for business next navigation season

Port Arthur, Ont.—Tenders will be received up till the 18th of September, 1913, for the interior fittings of a post-office. Plans and specifications may be obtained from Mr. J. A. Hastings, Toronto, and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

+—Prince Albert, Sask.—The Bank of Commerce has awarded ROBT. CLUNIE the contract for the erection of a bank building. The contract price is $30,000.

Prince Albert, Sask.—The Imperial Oil Company will erect a warehouse here. The estimated cost is $16,000.

+—Red Deer, Alta.—The Dominion Government has awarded MESSRS. NESBIT AND MILLER the contract for the construction of an armoury. The contract price is $36,000.

+—Regina, Sask.—The W. G. Downing Company has awarded Mr. THOMAS BARNARD the contract for the erection of a warehouse. The contract price is $45,200.

Regina, Sask.—Nearly 20 delegations from all parts of the province waited upon the Hon. Dr. Roche, Minister of the Interior, during his stay here. Various requests were presented, but the bulk of them consisted of applications for the erection of public buildings in different districts. Almost the entire day was taken up with their reception and the Minister had few leisure moments during his visit. He left for the east on Saturday night.

Saskatoon, Sask.—The Saskatchewan Abbatoirs, Limited, with head office here, will shortly erect a plant here. The company is capitalized at $200,000, and has just been successful in buying out the Northern Packing and Cold Storage Company, of Prince Albert.

Sorel, Que.—Tenders will be received up till the 18th of September, 1913, for supplying 20,300 cubic feet of white pine logs. Specifications may be obtained from the Department of Marine and Fisheries, Ottawa. Alex Johnston, Deputy Minister.

+—South Edmonton, Alta.—The Canadian Northern Railway has awarded Mr. GEO. McLEOD the contract for the erection of a station and freight sheds. The contract price is $40,000.

+—Toronto, Ont.—The PETER LYALL & SONS CONSTRUCTION COMPANY, of Montreal, have been awarded the contract for the erection of express offices and sheds, corner Simcoe and King Streets.

Toronto, Ont.—The Government has cancelled the contract for the building of the new barracks at Long Branch, Toronto. Michael Sullivan, of Kingston, the successful contractor for the erection of the proposed barracks, has received back his cheque for $65,000.

Vancouver, B.C.—Tenders will be received up till the 19th of September, 1913, for supplying the interior fittings for postal station "B." Plans and specifications may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

+—Vegreville, Alta.—The Dominion Government has awarded Mr. A. E. JENNINGS the contract for the erection of an armoury building. The contract price is $15,000.

Victoria, B.C.—Tenders will be received up till the 24th of September, 1913, for the construction of an addition to the public building. Plans and specifications may be obtained from Mr. Wm. Henderson, Victoria, and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

+—Winnipeg, Man.—The Dominion Government has awarded MESSRS. JACKSON & GOLDIE, LIMITED, the contract for supplying thirty additional targets for the Rifle Range. The contract price is $19,500.

+—Winnipeg, Man.—The Adanac Club has awarded the NATIONAL CONSTRUCTION COMPANY the contract for the erection of a club building. The VULCAN IRON WORKS were awarded the contract for the steel work. The building will cost $50,000.

The fire call

need not be a serious matter if your building is properly protected —or, better still, if it is also properly designed from the standpoint of fireproofness.

Whether the building that you contemplate erecting, or are erecting, is a little garage or a big six-story factory, it will pay you to make it as fireproof as possible. To do so does not necessarily mean extra expenditure. The cost of the improvements in design or equipment that we might be able to suggest would likely be fully balanced by the lower insurance rates that we could then obtain for the structure.

We desire to act without charge as consulting engineers—specializing on "fireproofness"—to any architects, owners or engineers. Make use of our services.

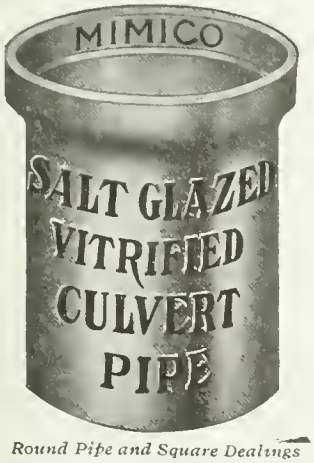
Sewers must carry the sewage quickly and surely to the distant point of disposal.



Therefore they must not only be laid in a proper gradient, but they must also be of a smooth material that will not cause delays in the flow of the sewage. Smooth, round, perfect, salt-glazed vitrified pipe, without blisters or scales and without cracks—in short, MIMICO PIPE—is absolutely required for a perfect sewer. It will pay you to get in touch with us.

Concrete Costs.

Tables and Recommendations for Estimating the Time and Cost of Labor Operations in Concrete Construction and for introducing Economical Methods of Management.

By FREDERICK W. TAYLOR, M.E., Sc.D., and SANFORD E. THOMPSON, S.B., Mem. Amer. Soc. C.E., Consulting Engineer. Small 8vo, xxii+709 pages, 82 figures. Cloth $5.00 net.

From the *Surveyor*, June 14, 1912:—"This book is one which no engineer or contractor can afford to be without, for even though the costs refer to American conditions and not English conditions, the method of procedure is one worthy of adoption."

SECOND EDITION, Revised and Enlarged.
TOTAL ISSUE—16,000.

Concrete, Plain and Reinforced.

By FREDERICK W. TAYLOR and SANFORD E. THOMPSON. 8vo, xl+807 pages. Cloth, $5.00.

In this edition is included the developments in the construction of reinforced concrete since the issue of the first edition.

SECOND EDITION, Revised and Enlarged.
TOTAL ISSUE—14,000

Principles of Reinforced Concrete Construction.

By F. E. TURNEAURE, Dean of the College of Engineering, and E. R. MAURER, Professor of Mechanics, University of Wisconsin. 8vo, x+429 pages, 17 plates, and 164 figures. Cloth, $3.50.

Covers in a systematic manner, those principles of mechanics underlying the design of reinforced concrete.

TENTH EDITION.

A Treatise on Masonry Construction.

By IRA OSBORN BAKER, B.S., C.E., D. Eng'g., Professor of Civil Engineering, University of Illinois. 8vo, xv+745 pages, over 100 tables, and 244 illustrations. Cloth, $5.00.

NINTH EDITION, Re-written.
TOTAL ISSUE—14,000.

JOHNSON - BRYAN - TURNEAURE

—The Theory and Practice of Modern Framed Structures.

In three parts. Part I—STRESSES IN SIMPLE STRUCTURE. 8vo, xii+326 pages, illustrated with cuts throughout the text. Cloth, $3.00 net.
Part II—STATICALLY INDETERMINATE STRUCTURES AND SECONDARY STRESSES. 8vo, xvi+538 pages, 313 figures. Cloth, $4.00 net.
Part III—DESIGN. (In preparation.)

TENDERS CALLED FOR

PLANS AND SPECIFICATIONS ON FILE.

The Canadian Engineer, 820 Union Bank Building, Winnipeg:—

ISSUE CLOSE

28-8—Supplying power house machinery, Neepawa, Man. 12-9

The Canadian Engineer, 62 Church Street, Toronto:—

The Canadian Engineer, 628 Transportation Building, Montreal:—

28-8—Supplying power house machinery, Neepawa, Man. 12-9

EXTENSION OF TIME.

TENDERS FOR MACHINERY.

TOWN OF NEEPAWA, MAN.

Sealed tenders will be received up to noon September 12th, 1913, for machinery for additions to the power plant at Neepawa, as follows:—

Specification Section No. 1— 2 72 ft. by 18 ft. boilers.

Specification Section No. 2—1 187½ h.p. engine.

Specification Section No. 3—1 150 K. V. A. generator exciter and switchboard.

Specification may be obtained by applying to W. E. Skinner, Limited, Consulting Engineers, 204 Sterling Bank Building, Winnipeg, or to the undersigned, or may be seen at the offices of *The Canadian Engineer*, 820 Union Bank Building, Winnipeg; 62 Church Street, Toronto, or 628 Transportation Building, Montreal.

J. W. BRADLEY,
Secretary-Treasurer, Neepawa, Man.

TENDERS.

RURAL MUNICIPALITY OF KILDONAN.

Sealed tenders addressed to the Reeve and Council will be received at the office of the undersigned up to 12 noon, on Wednesday, the 17th September, 1913, for the construction of 1,150 feet of 24 in. sewer on Ferry Lane, West Kildonan.

Plans, specifications etc., may be seen, and forms of tender obtained from the Engineer, Mr. F. Hill Parr, 215 Chambers of Commerce, Winnipeg.

The Council do not bind themselves to accept the lowest or any tender.

By Order,
H. THOMPSON,
Secretary-treasurer.

215, Chambers of Commerce, Winnipeg,
September 4th, 1913.

CAYUGA, ONT.

Sealed tenders will be received up to noon on the 16th day of September, 1913, by the undersigned at Cayuga, Ontario, for the construction of twenty-six and one-half miles of stone macadam road in the county of Haldimand.

The work will be let in three separate and distinct contracts, not necessarily to the same individual.

Tenderers are required to examine the localities of the work and are requested to be present at the opening of the tenders at 2 p.m., on Wednesday, the 17th day of September, 1913.

Plans and specifications may be seen at the office of the County Engineers, Messrs. Jackson and Kyd, Dunnville, or may be had from them on the payment of $10, which sum will be refunded on return of the documents.

Lowest or any tender not necessarily accepted.

T. A. SNIDER, K.C.,
County Clerk,
County of Haldimand,
Cayuga, Ont.

CITY OF REGINA, SASK.

Sealed tenders, registered and clearly marked on the outside of the envelope "Tender for Power-House Equipment," and addressed to the City Commissioners at Regina, Sask., will be received up till noon of October 1st, 1913, for the supply of:—

Coal bunkers, ash hoppers, coal and ash conveyers and crushers.

Price to be on equipment erected on foundation built by the City of Regina according to contractor's requirements.

A marked cheque for 5 per cent. of the amount of the bid, and made payable to the City Treasurer, City of Regina, must accompany each tender.

Specifications may be obtained from E. W. Bull, Superintendent of Light and Power, Regina, Sask.

The City Commissioners reserve the right to reject any or all tenders.

CITY OF REGINA, SASK.

Sealed tenders, registered and clearly marked on the outside of the envelope "Tender for Power-House Equipment," and addressed to the City Commissioners, Regina, Saskatchewan, will be received up until noon of October 25th, 1913, for the supply of:—

One 3,000 k.w. steam turbine, with condenser.

One 25-ton capacity, hand power crane for 45-foot span.

Specifications may be obtained from E. W. Bull, Superintendent of Light and Power Department, Regina, Saskatchewan.

A marked cheque for 5 per cent. (five per cent.) of the amount of bid must accompany tender.

The City Commissioners reserve the right to reject any or all tenders.

NEW INCORPORATIONS.

Blairmore, Alta.—Blairmore Coal Lands, $500,000.

Orono, Ont.—Pioneer Threshing Company, $10,000. E. N. Armour, E. MacMahon, R. S. Anderson.

Dundas, Ont.—Tocan Manufacturing Company, $250,000. A. C. Caldwell, W. A. Welsh, T. J. Palmer, both of Hamilton.

Ottawa, Ont.—Flexible Railway Supply Company, $1,000,000. C. Forth, D. Blair, G. H. Ferguson, Kemptville. The Grand Central Hotel of Ottawa, $40,000. E. J. Daly, J. P. Ebbs, W. N. Graham.

Montreal, Que.—Southern Canada Power Company, $3,000,000. C. H. Cahan, O. B. MacCallum, M. Lewis. Valley Construction Company, $250,000. A. D. Gall, R. B. Hutchinson, both of Westmount, L. Gosselin.

Toronto, Ont.—Pecol Drilling Company, $500,000, and 30 companies of $75,000 capital each; the provisional directors of all 30 companies are:—A. P. Poussette, A. A. Dickson, both of Toronto, S. Hogarth, of London, England.

Calgary, Alta.—Calgary Flour Mills, $5,000,000. W. C. Robertson, A. deB. Winter, F. A. McAllister. Hawk Eye Crushed Rock and Gravel Company, $20,000. J. B. Anderson, Lumber Company, $25,000. Murray's Limited, $30,000.

MEXICAN EAGLE ASPHALT

TRADE MARK

Adelaide Street West, Toronto, Ont., paved with Mexican Eagle Asphalt.

The principal streets in Toronto—both residential and business streets—are paved with sheet asphalt. The city has over 157 miles of this type of pavement, and has also laid some asphaltic concrete. The first sheet asphalt in Toronto was laid in 1887. The total cost of maintenance per square yard for the past 10 years has averaged less than 5½ cents a year. Toronto's experience with asphalt has been that it requires no repairs for the first 5 years and that it requires extensive repairs only after 10 years' wear.

For prices, analyses, samples, etc., please address

CURRENT NEWS.

San Francisco, Cal.—The San Francisco firm that obtained the contract for the two great floating caissons to be used at the entrance to the Panama Canal received orders to begin work on one of the big gates. The cost of constructing the caissons will be $400,000, and it will take 200 men a year to build it. The gate will be 113 feet long, 36 feet in beam, and 65 feet in depth. It will have a draft of 61 feet and will weigh about 10,000 tons. The two entrance gates are designed for use in case it is found necessary to close the canal to make repairs on the ocean sides of the first locks.

Port Arthur, Ont.—In connection with the visit to Port Arthur of M. H. McLeod, general manager, and other Canadian Northern Railway officials from the west, it is stated that the railway company will shortly negotiate with the Western Dry Dock and Shipbuilding Company for the building of two mammoth passenger lake liners, both of which, it is stated, would be larger than the Noronic. It is well known that the Canadian Northern will have to acquire a line of lake passenger steamers in order to compete with the Canadian Pacific and the Grand Trunk Pacific. The through C.N.R. transcontinental will be in operation next year, and all that will be lacking to surround the Canadian Northern with the prestige enjoyed by its competitors will be a steamboat line.

The National Paving Brick Manufacturers' Association's tenth annual meeting in Cleveland, O., on September 17th and 18th, will be marked by a paving conference which will attract city engineers and other officials and paving contractors from all parts of the country. The meeting will be exceedingly important in that it will bring together for the first time engineers from the leading cities of the country and almost the entire body of paving brick manufacturers. It will afford the engineers and paving brick manufacturers an excellent opportunity to discuss their problems on common ground. Both Cleveland and Cuyahoga County are adding largely to their mileage of brick pavements this year, and opportunity will be accorded to witness brick pavement construction in every detail from grading to grouting. The mornings of the 17th and 18th will be devoted to the business sessions of the Association. There will be no formal papers at the banquet to be held on the evening of September 17th, but full opportunity will be given to the visiting engineers to discuss what they have seen. At the last annual meeting the decision was reached to hold future conventions of the Association during a season of the year when brick road construction methods could be viewed in actual progress. Many engineers and contractors have written the Association that they are looking forward with much interest and pleasure to a personal inspection of the thousand miles of city streets and country roads of Cleveland and Cuyahoga County of which they have read and heard.

The September meeting of the Canadian Railway Club was held in Montreal on September 9th. A paper, entitled "Railway Efficiency," was read by Mr. A. Crumpton, Assistant Engineer of the Grand Trunk Railway. Election of officers to fill chairs made vacant by the resignation of Messrs. C. Murphy and D. Cromby also took place.

The Canadian Manufacturers' Association is holding its convention this year in Halifax, September 16, 17 and 18. Meetings will be held in the Technical College. The programme includes a number of outing trips of interest. The business of the convention will be dispensed with on Wednesday and Thursday.

CANADA Portland CEMENT

SOME men ask for so many bags of "cement"—

Others, more careful, say they want "Portland Cement"—

But the man who does the best work insists upon getting "Canada" Portland Cement—

And he looks to see that every bag bears this label

To specify Canada Portland Cement, is to introduce an additional safety factor into your calculations. Architects, contractors and engineers know the value of "making assurance doubly sure."

Advertisements under this heading one cent per word per insertion. Minimum charge fifty cents per insertion.

DO YOU NEED MALE HELP.—Canadian or foreign labor furnished for all classes of work, skilled or unskilled, for office, construction work, waterworks, paving, dams, and wharves. We can put men on the job for you cheaper than you can get them any other way, write or phone for particulars to O'Donnell's Employment Bureau, 116 Wellington Street West, Toronto. Phone Adelaide 3919.

MECHANICAL ENGINEER—Experienced Designer, Cost Estimator and Salesman, Works Supervision, all kinds of steam engines, boilers, hydraulic pumps, air machinery and mining plants, seeks position with Consulting Engineer, Contractor, Manufacturers or agency business. Highest references, some capital. Box 102, *The Canadian Engineer*, Toronto.

SUPERINTENDENT SEEKS re-appointment on heavy work, experienced in big plant, steam shovel work, rock, hardpan, concrete, etc. Highest references. Box 110, *The Canadian Engineer*, Toronto.

YOUNG CANADIAN ENGINEER.—Experience, paper mill, electric substation, hydraulic power plant, field and office, wishes to get in touch with a manufacturing concern requiring the services of a permanent resident engineer or plant chief; superior references. Address Box 112, *The Canadian Engineer*, Toronto.

YOUNG ELECTRICAL ENGINEER desires position either as consulting or plant engineer; first-class character and education; one who will take an interest and make good. Box 114, *The Canadian Engineer*, Toronto.

MECHANICAL ENGINEER resident in Toronto desires position; wide experience in manufacture and installation; would accept temporary post; references. Box 116, *The Canadian Engineer*, Toronto.

SUPERINTENDING ENGINEER of construction now free to accept appointment. Large experience on public works, with specialty in tunnelling. Unexceptional references. Nine years' U.S.A. experience. Address T. H. D., Bartram & Wadsworth, Bank of Toronto Building, Toronto.

EXPERIENCED MUNICIPAL ENGINEER and Land Surveyor desires position. Ten years' experience in municipal engineering, two years as superintendent of construction; also experience in construction of concrete bridges and buildings, railway and land surveys and drainage works. Toronto graduate; O.L.S. seven years, A.M. Can. Soc. C.E. five years. Engagement of three to six months' duration acceptable; at present in the West. Address Box 122, *The Canadian Engineer*, Toronto.

CIVIL ENGINEER; broad experience in the design of reinforced concrete buildings; can take off quantities for all classes of fireproofing; now employed wishes a change, can start on short notice. Best of references from England, United States and Canada. Knows English and French. Salary moderate. Box 126, *The Canadian Engineer*, Toronto.

CIVIL ENGINEER (40) with 18 years' experience in railway exploration and location, surveys, construction and maintenance, concrete foundations and bridge erection, at present engaged, will be open for employment about October 1st. Please reply Box 130, *The Canadian Engineer*, Toronto.

STRUCTURAL ENGINEER. Experienced in design; field and shop practice in structural steel and reinforced concrete, seeks technical commercial position. Address Box 132 *The Canadian Engineer*, Toronto.

ENGINEER, MECHANICAL and structural, desires responsible position, or would take an appointment as municipal or reinforced concrete engineer. Ten years' experience and very good technical education. Place of appointment no object. Apply to Box 134, *The Canadian Engineer*, Montreal.

SUPERINTENDENT, hustler, who gets results, wants position. Reinforced concrete, bridge or power plant. Just completed big bridge in Ottawa, Canada. Address E. A. F., 8 Clinton Street, Gloversville, N.Y.

Condensed Advts.

LIMITED

MONTREAL VANCOUVER

BRIDGE FOUNDATIONS

NEWCASTLE BRIDGE
OVER THE MIRAMICHI RIVER, N.B.

At a point where the Miramichi River is approximately 1400 feet wide, varying in depth from 35 to 45 feet, it was decided to build this new highway bridge.

Borings showed some 25 feet of soft silt overlying strata of clay mixed with sand and gravel extending to considerable depths.

Five caissons are to be sunk to depths varying from 45 to 55 feet below water level, where firm clay is reached, piles then being driven and cut off at this depth and concrete deposited.

The above shows our forces at work on the construction of the five piers and two abutments.

MARKET CONDITIONS

Montreal, September 6th, 1913.

Bar Iron and Steel.—Trade is reported active. Bar iron, $2.10 per 100 pounds; best refined horseshoe, $2.35; forged iron, $2.25; mild steel, $2.20; sleigh shoe steel, $2.20 for 1 x ⅜ base; tire steel, $2.30 for 1 x ⅜ base; toe caulk steel, $3; machine steel, iron finish, $2.25.

Cement.—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1.40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re-purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain.—The market is quoted per 100 lbs. as follows:—¼-in., $5.65; 5/16-in., $4.70; ⅜-in., $4.00; 7/16-in., $3.65; ½-in., $3.45; 9/16-in., $3.45; ⅝-in., $3.35; ¾-in., $3.25; ⅞-in., $3.15; 1-in., $3.05.

Explosives and Accessories.—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron.—The market is steady. Prices, basis, 28-gauge, are:—Queen's Head, $4.40; Colborne Crown, $4.20; Apollo, 10¾ oz., $4.30. Add 25c. per 100 lbs. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe.—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No 1 Summerlee, $22.50 per ton, selected Summerlee, $22; soft Summerlee, $21.50 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron, number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19.25 to $19.50 per ton, on track.

Lath.—See Lumber, etc.

Lumber, Etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph Poles: seven-inch top, cedar poles, 25-ft. poles, $2 each; 30-ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce, 4-ft x 1½-in., mill run, $3 to $3.25; pine, 4-ft. x 1½-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths. X, $2.10; XX, $2.40; XXX, $2.80.

Pipe.—Cast Iron.—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 4-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe.—Wrought and Galvanized.—Demand is fair and the market steady: —¼-inch $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ⅜-inch, $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent off for black, and 59 per cent. off for galvanized. The discount on the following is 72½ per cent. off for black, and 62½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 72½ per cent. for black and 62½ per cent. for galvanized:—2-inch, $36; 2½-inch, $57.50, and 3-inch $75.50; 72½ per cent. off for black, and 62½ per cent. of for galvanized; 3½-inch, $95; 4-inch, $1 08.

Toronto, September 10th, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron.—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel.—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates.—½-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes.—Orders continue active. Lap-welded, steel, 1¼-inch, 10c.; 1¼-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks.—In active movement. The price is $11.50 for grey stock, $13 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $13 to $15 per M., three grades.

Broken Stone.—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto, 60 cents.

Cement.—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm

Copper Ingot.—The market is lower at 15¾ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps.—75c. and $1 per 100; case lots, 5,0000, 20 per cent. off.

Dynamite.—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¼ cents pound. 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1½c. per hundred. For 10-case lots and over deduct ¼ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1¼ cent.

Fuses.—Electric Blasting.—Double strength, $3.50 per hundred, advance 5c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 5c. per hundred for each 2-in. wire additional.

Iron Chain.—¼-inch, $5.75; 5-16-in, $5.15; ⅜-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3.55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe.—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1¼-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40.60; 6-inch, $52.64. Galvanied Pipe, ¼-inch, $2.86; ⅜-inch, $2.86 ½-inch, $5.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead.—Firmer, $5.25 to $5.50.

Pig Iron.—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar.—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate.—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $6; green, $8, with a prospect of advance. Dealers are fairly busy.

Sand.—Sharp, for cement or brick work, $1.25 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe.—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0.25	$0.40	$0.65	$1.00	$ 3.85
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00
Double junctions	1.25	2.00	3.25	5.00	16.25
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. H. traps	2.00	3.20	6 50	25.00	.....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes, 9 inches and under or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels.—Active.—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1¾ by 3-16 and larger, $2.50 to $2.75; tees, $2.75 to $3 per 100 pounds. Extra for smaller sizes of angles and tees.

Sheet Copper.—22c. per lb.

Sheet Steel.—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized.—Apollo Brand.—Sheets, 6 or 8 feet long, 30 or 36 inches wide; 10-gauge, $3.00; 12-14-gauge, $3.00; 16, 18, 20, $3.30; 22-24, $3.40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 pounds. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin.—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel.—Jewett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates.—3-16-inch, $2.40 per 100 lbs.

Zinc.—Spelter.—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, September 9th, 1913.

Anvils.—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10½ to 10¾c.; anvil and vise combined, each $5.50.

Bar Iron.—$2.50 base.

Bars.—Crow, $4.50 per 100 pounds.

Beams and Channels.—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick.—Kiln run per M, $13; sewer per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland.—$2.40 to $2.50 per barrel.

Chain.—Coil, 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7-16, $4.75; ½, $4.50; 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ¾, 5¾c. Tie out, 70 and 10 per cent.

Copper.—Tinned, boiler, 26½c., planished 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent discount.

Dynamite.—$11 to $13 per case.

Galvanized Iron.—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20, $4; 18, $3.95; 16, $3.90; Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30; 22, $4.30; 20, $4.10 per cwt.

Iron.—Swedish iron, 100 lbs., $4.75 base; sheet, black, 24 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26-gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American, $5.15; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe.—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7.80; 1½-inch, $9.35; 2-inch, $12.50; galvanized—½-inch, $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch.—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled.—3-16-in., $3.35 base; machinery, $3 base; share, $4.50 base; share crucible, $5.50, cast share steel, $7.50; toe calk, $4.50 base; tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel.—8½ to 15c. per pound

The Canadian Engineer

A weekly paper for engineers and engineering-contractors

THE WATER LEVEL OF LAKE ERIE

REPORT OF THE INTERNATIONAL WATERWAYS COMMISSION ON THE VALUE OF COMPENSATING WORKS IN THE NIAGARA RIVER —A SEQUEL TO 1910 REPORT AGAINST ATTEMPT AT REGULATION

THE International Waterways Commission, the duties of which, when instituted in 1902, included an investigation into the advisability of locating a dam at the outlet of Lake Erie with a view to determining whether such a dam would benefit navigation, and, if the structure was deemed advisable, a report to the governments of Canada and the United States containing recommendations relative to the construction of of the same, and an estimate of the probable cost, has recently submitted its report.

Upon undertaking the work, the commission first divided it into two parts. It first investigated the advisability of regulating works to reduce the oscillation of the lake, thereby raising the low-water level but not affecting the high-water level. This part of the problem was reported upon in January, 1910, the commission finding that material improvement in regulation could not be accomplished except at the expense and to the injury of the channel below. In the case of Lake Erie it would be possible to raise the extreme low-water stage about 1 ft., and this in turn would raise the low-water stages of Lake St. Clair about 0.61 ft. and of Lake-Huron-Michigan about 0.27 ft., all without appreciable increase in the extreme high stages. But in doing this the low-water stage of Lake Ontario would be lowered about $4\frac{1}{2}$ in., the available depth in the St. Lawrence Canals would be diminished about $7\frac{2}{3}$ in., and the city of Buffalo would suffer by increased damage from floods and by a postponement of the date of opening navigation in the spring. The question of damage to vested rights was thus introduced. While the advantages of regulation might outweigh the disadvantages if the persons who were to benefit from the former were identical with those who were to suffer from the latter, the difference was not great enough to justify the two governments in entering upon the vexatious question of damages. The commission therefore recommended that the regulation of Lake Erie be not undertaken, meaning thereby the most complete practicable regulation such as can be secured by a dam and sluice gates located at or near Buffalo.

The second branch of their work, viz., the advisability of compensating works for raising the level at high as well as at low-water, without complete regulation, is the subject of a report under date of June 20th, 1913.

In July 3rd issue of *The Canadian Engineer* mention was made of the recommendations of the commission in this respect. A copy of the entire report has since been received, and we extract from it herewith.

As was stated in the former report, the Niagara River at its extreme upper end is an important safety valve for the protection of Buffalo from the effect of storms, and should not be obstructed by a dam, but it seemed possible that somewhere in the river, between Lake Erie and the Falls, a submerged dam might be placed which would greatly benefit the navigation of the waters above without injury to those below and with only minor damages, if any, to the adjoining lands. To determine this question it was necessary to make a complete survey of the Niagara River from Lake Erie to the Falls, including the topography of the adjoining lands. The survey was made by the commission. A survey was made also by the Canadian Government of the Welland River, in Canada, which enters the Niagara about a mile above the rapids approaching the Falls. A sketch upon a reduced scale, showing the Niagara River in outline, is shown in Fig. 1.

From a study of the maps it appears that the best site for a submerged dam, or weir, is just above the Welland River, extending from Hog Island, at the mouth of that river, to the mouth of Gill Creek, on the American side. As the Welland is a navigable stream, there would be some advantage in placing the weir below its mouth, but the survey of that river showed that a moderate increase in the height of its surface would submerge a considerable area of valuable land. To provide for the navigation of the Welland it is necessary to construct a lock at the Canadian end of the weir. The object of placing the weir as near as possible to the foot of navigation is to improve all of the navigable portion of the Niagara River above. A study of the topography on both sides of the Niagara River showed that the water surface at mean stage could be raised as much as 3 feet at the site of the weir without inflicting damage upon adjacent lands, except for a distance of about $1\frac{1}{2}$ miles immediately above the weir on the American side. At this place it is proposed to construct a levee of suitable height to protect the land from overflow.

The form to be given the weir has been the subject of careful investigation. In order to disturb as little as practicable the natural distribution of flow through the different parts of the cross-section of the river, the crest of the weir is broken into four sections, as shown in Fig. 2, the height given to each section being such as will raise

the surface of the water in that section 3 feet at mean stage.

A cross-section of the weir is shown in "A" of Fig. 3. This form was adopted after experiment with various types of weir made under as nearly as possible true river conditions. The experiments were made at the hydraulic laboratory of the college of civil engineering at Cornell University, which was generously placed at the disposal of the commission for the purpose.

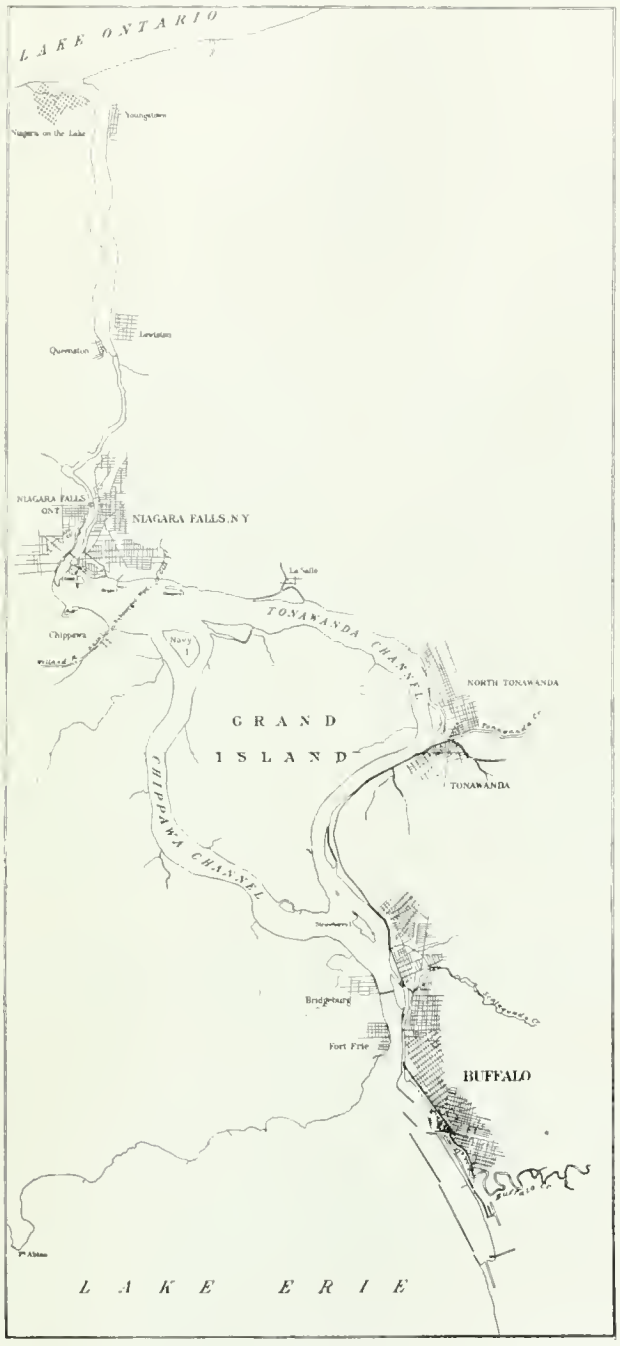

Fig. 1.—Niagara River, Showing Location of Submerged Weir.

The form of weir which was subsequently adopted fills the desired condition of high efficiency at high stages of the river and correspondingly the flow efficiency at low stages. The weir would raise the level of Lake Erie 0.51 ft. at extreme low stage, 0.39 ft. at mean stage, and 0.11 ft. at extreme flood stage. At low-water the surface of the Niagara would be raised 1.08 ft. at the Buffalo waterworks, 1.16 ft. at Strawberry Island, about 5½ miles from the lake, increasing to 3.05 ft. at Schossler's Dock, the foot of navigation. At flood stage these numbers are: For Buffalo waterworks, 0.19 ft.; for Strawberry Island, 0.12 ft.; and for Schossler's Dock, 0.91 ft.

The effect of raising the mean level of Lake Erie 0.39 ft. would be to raise Lake St. Clair's mean level about 0.23 ft., and that of Lake Huron about 0.09 ft.

To change the level of a great inland sea like Lake Erie, upon the shores of which are many populous cities, is a matter to be approached with caution. Any important increase in the height of the high-water level may cause serious damage to the wharves and low-lying lands. Care must be taken to avoid injury to vested rights. In this case, the ordinary high-water level is increased only 0.38 ft., or 4½ inches, and the extreme flood stage at Buffalo is increased only 0.11 ft., or 1⅓ ins.

The construction of the weir recommended in this report will affect to some extent the levels in the first reach of the Barge Canal from Tonawanda to Lockport. The level of the Niagara River at Tonawanda would be raised by 1.71 ft. at mean stage, and by 0.55 ft. at flood stage, so that inasmuch as no provision has been made at the entrance of the canal against the rise which the construction of the weir will cause, it is in our opinion necessary to provide for the construction of a guard lock, the cost of which is included in our general estimate.

The capacity of the lock to enter the Welland River is a domestic question to be decided by the Canadian government. An item of $500,000 in the estimates provides for the construction of that lock, but its dimensions should conform to the capacity which the Canadian government shall determine to give to the connecting waterways, and this estimate can be regarded only as a rough approximation.

The weir is to be constructed of concrete and its cost is estimated as follows:

Rock excavation, 36,300 cubic yards, at $4 per yard	$145,200
Concrete, superstructure, 44,000 cubic yards, at $12 per yard	528,000
Concrete substructure, 48,500 cubic yards, at $10 per yard	485,000
Cofferdam, 105,500 cubic yards, at $3.50 per yard	369,250
Pumping and maintenance, lump sum	210,000
Lock into Welland River	500,000
Guard Lock at Tonawanda	500,000
Excavation for retaining walls along Niagara River, 16,000 cubic yards, at $3 per yard	48,000
Concrete for retaining walls, 12,500 cubic yards, at $10	125,000
	2,910,450
Add for engineering and contingencies about 20 per cent.	589,550
Total	3,500,000

The great value to the navigation interest of an increase of 6 inches in the low-water depth of Lake Erie has already been pointed out. The improvement of Niagara River to be effected by the proposed weir is important. An incidental advantage in its construction is that it would eliminate the possibility of the power companies at the Falls having any injurious effect upon the level of Lake Erie. The Niagara River below the weir and the conditions upon Lake Ontario and the St. Lawrence River would remain without appreciable change. The weir has small regulating effect upon the levels of Lake Erie, the range of the oscillations of the lake being reduced about 4½ per cent. The average natural low stage, 571.3, is raised 0.45 ft., and the average natural high stage is raised 0.38 ft., a difference of 0.07 ft. The storage in Lake Erie is reduced only by that amount, which is not sufficient to affect the level of Lake Ontario seriously.

It is possible that the Canadian government may prefer to assume the damages from overflow in the valley of

the Welland River, which would be caused by placing the Canadian end of the proposed weir below the mouth of the Welland, and thus make the lock unnecessary. If so, provision for this should be made in any treaty.

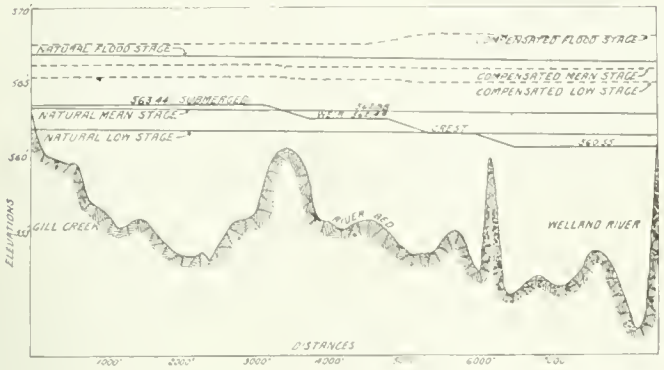

Fig. 2.—Natural and Compensated Stages at Site of Submerged Weir.

The commission believes that the very great advantages to navigation interests will justify and amply repay the necessary expenditure, and recommends that a treaty be entered into between Great Britain and the United States providing for the construction of the weir.

The report has appended to it the findings of Messrs. W. J. Stewart, engineer for the Canadian section, and E. E. Haskell, engineer for the American section, and the following is extracted therefrom:

Niagara River is the outlet of Lake Erie and discharges into Lake Ontario; it is divided into two reaches by the Falls, the "upper" and the "lower." The upper reach is navigable from Lake Erie to Chippewa, Ontario, and to Niagara Falls, N.Y., and is the reach with which we are at present concerned. Strawberry and Grand Islands divide a part of this reach into two channels, known as Tonawanda and Chippewa. The distance from Lake Erie to the head of Strawberry Island is approximately 4 miles and the fall in this distance at mean stage is 5.8 feet. The distance from the head of Strawberry Island to the end of navigation by the Tonowanda Channel is 16½ miles, and between the same points by the Chippewa Channel is 12¾ miles. The fall in these reaches at mean stage is 4.8 feet.

The natural conditions in this upper reach of river are therefore such as to indicate that by placing a submerged weir of proper size at the end of navigation, or below Navy and Connors Islands, it might be possible to create sufficient backwater to restore to Lake Erie a part at least, of what it has lost in stage by diversions, and at the same time greatly improve the navigation of the reach of river under consideration.

It was this project that was in mind when the last report was submitted. Naturally, the question arises: Can the water be raised sufficiently at the location indicated to actually restore to Lake Erie a quantity worth while and at the same time keep within control all flood waters, particularly those that come from heavy southwest windstorms on Lake Erie?

To answer this question it was necessary to have more data than existed at the time of our previous report. A careful topographic survey was required of all lands likely to be affected and a type of weir best suited for the location and conditions had to be determined.

Surveys were started early in 1910 and prosecuted as diligently as the affairs of the commission would permit. The results from these did not become available, however, until about the beginning of the present year. A detailed topographic survey was made of the shores of the Niagara from Lake Erie to within a mile of the Falls; the islands within this reach; and of the Welland River from its mouth to its source, a distance of about 40 miles.

In order to determine the best type of weir, it was deemed necessary to study various types under as nearly as possible true river conditions. These studies were made at the hydraulic laboratory of the college of civil engineering of Cornell University. They covered experiments on seven different types, ranging in height from 3.7 to 6.02 ft. and having in general a 3 to 1 upstream slope and a 1 to 1 downstream, five having a flat crest and the remainder a rounded crest. In two of the flat-top types, the upstream, and in all the downstream corners were rounded on a radius of 9.5 ft. On two of the flat-top and all of the round-top types, the downstream nappe was an ogee curve.

These experiments furnished what was being sought, namely, a type of submerged weir that would be very efficient at high stages and much less so at low stages.

Fortified with these new data, a study was made of the probable effect of submerged weirs placed at right angles to the general direction of the river in the following localities: Willow Island, Port Day, Grass Island, and Gill Island, as well as one on a line between Gill Creek and Hog Island, at the mouth of Welland River. Only the last of these met the conditions desired, and it is not thought necessary to give the results of the studies of the rejected locations because the end to be attained is clearly set forth in the consideration of the site finally chosen.

Fig. 3.—Experimental Coefficients and Cross-Sections of Weir Models.

As shown in the previous report, the stage of water in several of the Great Lakes will be materially lowered by artificial diversions of water therefrom. This loss of level on Lake Michigan-Huron, if 10,000 c.f.s. be taken

through the Chicago Drainage Canal, will for mean stage amount to 0.53 ft., while the loss of level to Lake Erie due to this diversion and 1,000 c.f.s. through the Erie Canal and 1,100 c.f.s. through the Welland Canal will at mean stage amount to 0.43 ft. and 0.09 ft., respectively, a total of 0.52 ft. The American power companies have also lowered the level of Lake Erie probably by 0.08 ft.

The project here proposed for restoring the loss caused by these diversions is the construction of a submerged weir of suitable type, on a line between Gill Creek and Welland River, as shown in Fig. 1, of such a height of crest as will create sufficient backwater to offset it.

To determine this, backwater curves have been computed, based upon Bernoulli's theorem for steady flow. The backwater on Lake Erie caused by the submerged weir has also been computed by the supply, storage, and discharge method, and the results by the two methods check very satisfactorily, the latter giving 0.07 ft. greater backwater in the high-water year of 1876 and 0.08 ft. greater in the low-water year of 1895.

Owing to the fact that the weir has an increasing efficiency with increase in stage, it was thought that the flow of the river might vary slightly from present natural conditions and therefore might affect injuriously the stage of water in the St. Lawrence Canals. The computed results show that the effect on Lake Ontario of any variation in the flow from Lake Erie caused by the submerged weir would be negligible.

Submerged-Weir Experiments.—As previously stated, submerged-weir experiments were made upon seven different types of weirs, ranging in height from 3.70 to 6.02 feet. All of the models were approximately 4 feet long. The following table, No. I., gives the dimensions of the several models tested:—

Table No. I.—Dimensions of Submerged-Weir Models.

Model No.	Length	H't	Crest	Width bottom	Upstr'm face	Downstream face	Remarks
	Feet	*Feet*		*Feet*			
1	4.005	6.02	Flat, 6 feet wide	31.76	1-3 slope	1-1 slope	Upstream corner sharp, downstream corner rounded, radius 9.5 feet
2	4.01	4.53	do.	25.79	do.	do.	do.
3	4.01	4.53	do.	27.33	do.	do.	Up and down stream corners rounded, radius 9.5 feet
4	4.02	5.17	Rounded, radius 9.5 feet	27.70	do.	do.	Ogee curve downstream face
5	4.005	4.35	do.	23.50	do.	do.	Ogee curve bottom, downstream face
6	4.005	3.70	Flat, 6 feet wide	23.50	do.	do.	Upstream corner sharp, downstream corner rounded, radius. 9.5 feet. Ogee curve bottom, down stream face.
7	4.005	3.76	do.	25.04	do.	do.	Up and down stream corners rounded, radius 9.5 ft. Ogee curve bottom downstream face.

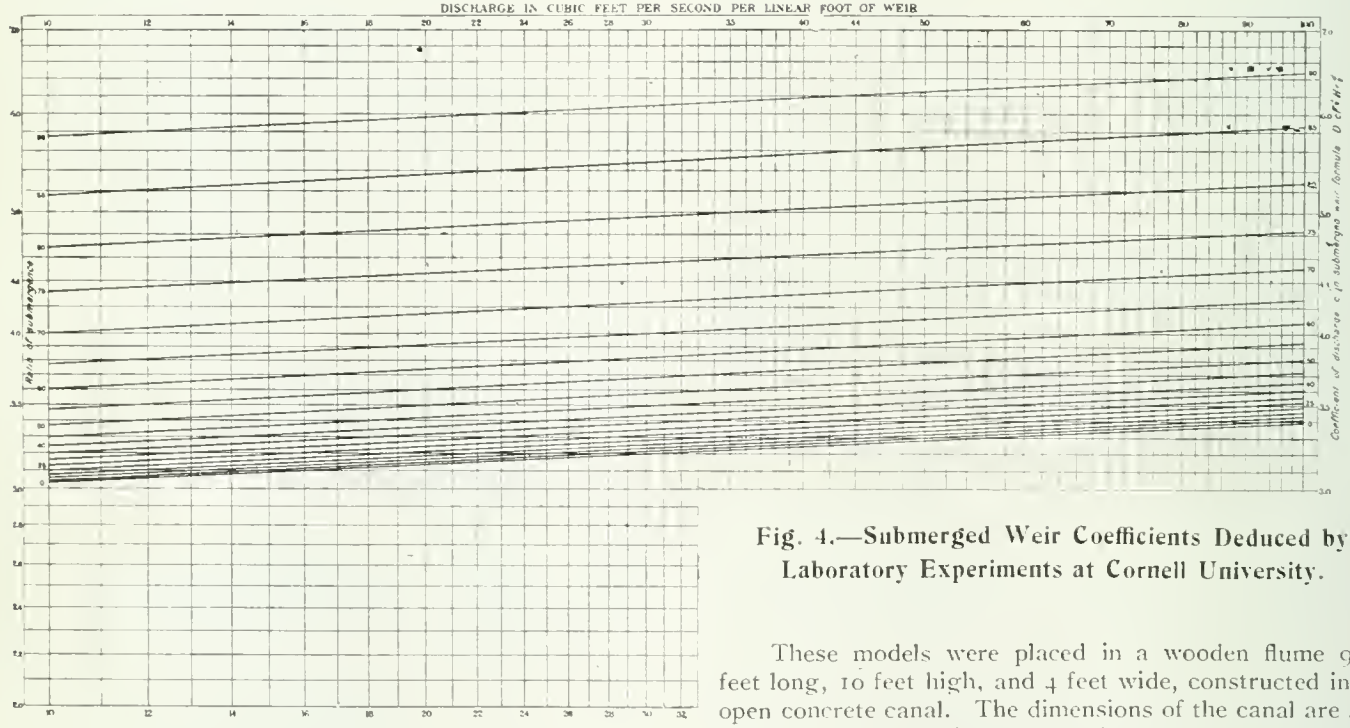

Fig. 4.—Submerged Weir Coefficients Deduced by Laboratory Experiments at Cornell University.

Knowing the elevation of the flood waters of this new compensated flood stage from Lake Erie to the site of the proposed weir, the topographic surveys previously referred to were studied with a view to determining the effect that these new flood waters might have upon adjacent lands. So far as can be seen, but little, if any, damage would result from the proposed weir placed on the Gill Creek-Welland River section. The investigation has also shown that it would not be possible to raise the water at the weir by much more than 3 feet without danger of damage from floods.

These models were placed in a wooden flume 95.5 feet long, 10 feet high, and 4 feet wide, constructed in an open concrete canal. The dimensions of the canal are 418 feet long, 16 feet wide, and 10 feet deep. The grade of bottom of channel is approximately 1 foot in 500. A bulkhead located about 60 feet from upper end of canal divides it into two parts. A standard sharp-crested weir placed on top of this bulkhead measures the quantity of water flowing in canal. The wooden flume mentioned above was built in this canal, the upper end being located about 87 feet below the standard weir. The upper end of flume had a bell-shaped mouth, about 15 feet long, converging from 16 feet, the width of canal, to 4 feet, the width of flume. The crest of weir of tested models was placed about 46 feet below upper entrance to bell mouth. The flow of

water over the standard weir, through the canal, and over the experimental models was regulated by gates at the head and foot of canal. By the manipulation of these gates various discharges, submergences, and heads on the experimental weir models were secured. The upstream head was measured in the flume with a plumb-bob attached to steel tape at a point about 25.5 feet above the upstream edge of crest of flat weir, while the downstream head was measured in the same way in still water behind the flume on both sides and about 16.6 feet downstream from the upstream edge of crest of flat weir. The longitudinal water surface curve over the weir was determined for all models under various conditions of flow. The flow of water over these experimental models varied between 27.6 and 203.2 second-feet, equivalent to 6.87 and 50.75 c.f.s. per linear foot of weir, respectively. The upstream heads on the weir varied between 1.66 and 6.35 feet and the ratio of submergences between 0 and 95. The experimental coefficients as derived are based upon the submerged weir formula $D = cF^{\frac{1}{2}} \left(H + \frac{d}{2} \right)$, where D = discharge per linear foot of crest, H = upstream head, d = downstream head, F = fall or upstream head minus downstream head, c = experimental coefficient. The weir coefficients for the flat-crest models are given in Table II. and are shown in Fig. 3.

Table No. II.—Weir Coefficients, Flat-top Model.

Weir condition	Average minimum river flow per linear foot of weir	Co-efficient	Average mean river flow per linear foot of weir	Co-efficient	Average maximum river flow per linear foot of weir	Co-efficient
	C.f.s.		C.f.s.		C.f.s.	
Free	18 00	3 120	25.00	3 160	45.00	3.260
0.1 submergence	18 00	3.145	25.00	3.190	45.00	3.300
0.2 submergence	18.00	3.195	25.00	3.245	45.00	3.345
0.3 submergence	18.00	3.260	25.00	3.308	45 00	3.419
0.4 submergence	18 00	3.340	25.00	3.397	45.00	3 500
0.5 submergence	18.00	3.480	25.00	3.540	45.00	3.655
0.6 submergence	18.00	3.720	25.00	3.780	45 00	3.900
0.7 submergence	18 00	4.125	25.00	4.190	45 00	4.320
0.8 submergence	18.00	4.850	25.00	4 910	45.00	5.060
0.9 submergence	18.00	5.930	25.00	8.025	45.00	6.210

The weir coefficients of the rounded-crest models were about 5 per cent. greater than those of flat-crest models, but the coefficient increment was about the same for each type within the limits for river conditions. The flat-crest model was therefore adopted on account of the easier construction, inspection, and repair.

The committee does not wish it understood that the type of weir here proposed is the most desirable one for the purpose. The experiments made were by no means sufficient to settle this question. It is very probable that further experiments would reveal a still better type. The one proposed does demonstrate, however, that the project is feasible.

SILICON STEEL FOR ELECTRICAL PURPOSES

The results of extended experiments shows that silicon steel is to be preferred to manganese steel for electrical purposes on account of its superior magnetic properties is the statement made by F. Goltze in a paper read before the German Foundrymen's Association, Berlin. Annealing improves the structure and the mechanical properties, and has considerable effect on the magnetic properties, at 750° C. reducing them slightly and at 1,000° C. establishing a marked improvement, while at 900° C. it has a decidedly adverse influence. Coarseness of grain and good magnetic properties were found to go hand in hand. The addition of aluminum to cast-iron was also found to increase the magnetic properties of the iron.

BASIC OPEN-HEARTH STEEL CASTINGS.*

By H. F. Miller.

FOR some years the prejudice against basic open-hearth steel for castings has been gradually decreasing. Acid steel has been used for this purpose much longer than basic steel; and the melters in acid practice had it well in hand when basic steel was first tried. Then the necessity of learning a new set of laws for the production of satisfactory basic open-hearth steel for castings became evident. The first of these laws has to do with the furnace construction. The charge should be melted down as speedily as possible to prevent excessive oxidation.

Furnace Hearth.—The hearth of the furnace is a decisive factor in the production of solid castings. The manufacturer should know the size of the heats he intends to make constantly, and should have his furnace built for that size of heat. The hearth should differ in dimensions from that of a furnace making ingot steel. That is, the bath should be deeper and should have less surface area. A shallow bath permits the slag to come out soon after the steel commences to flow, and thus prevents the additions from going into the steel, or from becoming uniformly distributed should they be put in hurriedly.

Under this head comes the very poor practice of making small heats in hearths of a much larger capacity. If into a 25- or 30-ton furnace only 12 or 15 tons of metal is charged per heat, the proportion of heats that will be wild or show signs of wildness at some time during the pouring will be comparatively large; whereas, if the hearth is charged to capacity, a heat showing signs of wildness will be a rare occurrence.

Influence of Slag.—The nature and action of the slag is an important factor in the manufacture of quiet steel. Slags are usually roughly classified by the melter according to physical appearance, as follows:—

(1) The dry, heavy slag occurring when there is very little silica present. This is a dangerous slag if not carefully worked. The burning of many furnaces is due to reflection of the heat to the roof by this slag. Another danger is that the melter, deceived by the physical appearance of the slag, may add an excessive amount of fluorspar. This results in the ladle being badly cut and the stopper rod burned off. These disasters can be prevented by a gradual addition of spar until a "wet" slag is created, after which the heat may be worked down as usual. With natural gas the heat will form for some time.

(2) A wet but lumpy slag is a good slag with which to work. The lumps of limestone should be broken up with a rod, so that a rocky bottom may be avoided. Otherwise an unbroken lump will choke the tap-hole, so that the flow of the slag being stopped, the steel is left uncovered until the tap-hole can be freed. A large amount of heat is lost from the steel thereby. A lumpy slag can be avoided by charging small-sized limestone.

(3) A third slag is the very watery variety, usually occurring when heats melt at high temperature, by reason of the presence of an excessive amount of silica. This slag should have burned dolomite or raw limestone added until a thick slag is made. When the slag is too thin, it will mix with the steel in tapping and a wild steel will be the product. The ladle and stopper rod will be badly

*Abstract of a paper presented before the American Institute of Mining Engineers (Iron and Steel Division).

scorified, and usually some tons of steel will go into the pit by reason of a burned-off stopper rod.

The ideal slag is heavy and wet with no large lumps. This slag makes an easy heat to work and gives a steel low in phosphorus and sulphur. It requires but a small amount of fluorspar to put this slag in shape for the ladle A heavy slag of this nature will not mix with the steel, and will generally stay in the furnace until the steel is nearly all in the ladle. It also has the good quality of cutting neither the stopper rod nor the ladle brick. The only objection is that it causes a dirty bottom, and unless a washout is made after each heat the bottom will rise to the sill-plate level after a few heats. This result shows very poor practice. No time is ultimately gained by charging up without the usual washout. If a washout from 20 to 30 min. is made after each heat, the furnace will work fast for a much longer time. Moreover, the holes that occur in a high bottom will be largely avoided, if the bottom is kept low and clean.

Tap-Hole.—The tap-hole should be kept large and low. The quicker steel gets into the ladle, the more heat is retained. The shorter a spout the better, for the same reason. Moreover, a large tap-hole will not clog up easily if rabbling has to be done; and few hard taps will occur. For shutting up the tap-hole magnesite is best, because it does not burn together and make a hard tap, nor does magnesite boil out, as may happen when a tap-hole is closed with green dolomite. Burned dolomite, however, may be safely used, the only drawback being an occasional hard tap, due to the burning together of the material.

The foregoing facts are probably known to most smelters; but unless vigilance is constant, one factor is apt to be overlooked. The bottom may be low and the tap-hole all right; but the spout if not smooth at the end may cause the stream to spray over the ladle, thus losing much heat and causing a skull and, perhaps, some misrun castings, all of which could be avoided with a carefully made up spout.

Alloys.—The addition of alloys may be made in the bath or in the ladle. By putting them into the bath, much heat is saved. This is a valuable method where a furnace is working cold or a heat has melted low and there is difficulty in getting it hot. The advantage is that the additions are made while the flame is still on the bath, and the loss of the heat in the bath caused by dissolving the alloys can be regained. The objections are:—(1) That a large amount of each alloy must be added, since in this method from 15 to 30 per cent. goes into the slag; (2) that the silicon, reacting, will throw back the phosphorus into the steel. Putting the additions into the steel as it goes into the ladle is the better method. A uniform distribution of alloys is obtained by shovelling the alloys in gradually. If the alloys are added to the ladle, the steel will be helped greatly by first raising them to red heat, especially in winter.

After the heat has melted down and the limestone has boiled up, the charge will be benefited by allowing it to "soak" from 15 to 30 min. This will allow any contained slag to rise and also much of the gases. Ore may then be fed if necessary or, if the heat has come ready, it remains only to get the steel hot. Sometimes heats will melt low, and if only small ladles are available or there are no heavy castings to pour, it is best to get the heat ready by using manganese. This will not add much metal to the bath, and it is a good substitute for pig-iron.

With large ladles, working the heats with both pig-iron and manganese is recommended. Very little, if any, ferro-silicon should be used instead of manganese, since the silicon mixes with the slag and cuts the stopper rod off while the heat is being poured. Hot metal is preferable to cold additions, as the bath is not then chilled by the additions.

If the slag comes too quickly and all the additions have to be made to the first part of the heat, an even distribution can be obtained by rabbling the heat. If some of the additions are lost in the slag, or if insufficient has been put in, the heat showing signs of wildness, a simple remedy is to take a number of sticks of aluminium, bend a tapping rod around them, thrust them to the bottom of the ladle, stir the bath with them and rabble it afterwards if necessary. There is hardly a heat that cannot be made absolutely quiet by this means. But it is curative treatment, and a good preventive is always better.

The time consumed in pouring is a factor in determining the size of the heat. Good practice demands that a heat of steel should be poured in less than 60 minutes; the faster the better. The high temperature required to pour steel from 1 to 2 hours causes a great increase in occluded gases and necessitates an increase of about 30 per cent. of ferro-silicon to make it as quiet as when poured at a lower temperature.

The use of fluorspar seems also to make the steel less responsive to the quieting action of silicon, since the fluorine appears to be absorbed by the steel. I have noticed when pouring a test that after much spar has been used the steel gives off a smoky gas of the same appearance as when fluorspar is added to the bath. If this is true, the action of fluorspar cannot be beneficial to steel when added in large quantities. Good basic steel is harder to make than good acid steel; but if the practice outlined is followed, the steel produced will be as quiet while molten and as solid afterwards as acid open-hearth steel —and tougher.

FORCE EXERTED BY EXPANSION OF WOOD.

The great pressure exerted by the expansion of wood when soaked with water has been illustrated during the flood at Dayton, Ohio. A quantity of oak dashes veneered with maple was stacked to within one inch of a reinforced concrete girder in the basement of a factory. This girder had a cross-section of 12 by 19 inches and supported a 6-inch reinforced concrete floor. The basement was flooded, and after the water receded it was found that the girder, together with the concrete floor which it supported, had been lifted 3 inches. Ten weeks after the flood the girder still rested on the dashes, but it had settled about ¾ inch. Large cracks developed in this girder, starting at the edge of the pile of dashes and extending upward and outward. These cracks extended from the bottom to the top of the section at an angle of about 30 degrees with the horizontal. It was necessary to replace this girder and a section of the floor.

In these days, when hydro-electric power is becoming so important a factor in industry, it is of interest to note that in the Western Provinces there are vast possibilities in this regard. In Manitoba there is water power which would produce 7,000,000 horse-power, and only 78,000 horse-power is being utilized. This is at Winnipeg, which has a municipally-owned hydro-electric plant, supplying light and power to consumers at cost.

THE EXPRESSION OF PIVOT ERRORS BY A FORMULA.*

By R. Meldrum Stewart,
Dominion Observatory, Ottawa.

EVEN the best measurements of pivot errors of a meridian circle or transit instrument are, of course, affected by accidental errors, and in the case of fairly good pivots these are no doubt larger than the actual deviations of the pivots from a smooth curve. It then becomes a question what pivot corrections should be adopted, both for the zenith distances at which the errors have been observed, and for intermediate zenith distances. The practice ordinarily followed is to plot the observed values and draw a smooth curve representing them as closely as possible. The objection to this proceeding is that it is not a definite one, and, what is perhaps more serious, that the amount of smoothing does not, as it should, depend on the accuracy of the original observations (for it is manifest that accurate observations should be smoothed less than inaccurate ones). It has seemed, therefore, that it would be advantageous, if possible, to obtain from the observations a definite formula which might be used in place of the smoothed curve, and from this formula to construct tables showing the zenith distances at which the pivot corrections change from unit to unit. In a recent series of measurements at the Dominion Observatory it was found that a good representation could be obtained by the use of a few terms of a Fourier series, and it seems probable that the values so adopted are more accurate than the actual observed values.

It is evident that a Fourier series can be made to represent the observed values to any required degree of accuracy; for example, in the case where the pivot errors are observed at intervals of 6°, the use of 72 terms would reproduce the observed values exactly. Since, however, these observed values contain errors of measurement, it is probable that a more exact representation of the actual pivot errors will be obtained by omitting the terms with small co-efficients; it then becomes a question simply of the number of terms to be retained.

It is evident that, the more accurate the original observations, the more closely the adopted curve should be made to represent them. Also, the accuracy of the observations is represented by the probable error of a single observation, computed in the usual way; since several complete sets of observations are always made, this is readily obtained. Hence the deviations of the adopted curve from the observed values should be a function of the observed probable error. But by treating these deviations as residuals they themselves may be utilized to form another probable error, which represents the accuracy with which the adopted curve reproduces the observed values. The most obvious assumption is that these two probable errors should be made equal that is, that sufficient terms should be included in the Fourier series (choosing always the largest terms) to make its representation of the observed values equally accurate with the representation of the true values by the observations themselves.

Freed from technicalities, the above process simply amounts to drawing a smoothed curve in a particular way, with the adoption of a criterion for the amount of smoothing. The tentative adoption of a particular number of terms amounts to drawing a trial curve; if upon examination it is found that it is an even chance that the discrepancies between the curve and the observed values are due to errors of observation, the curve is adopted; if not, another trial curve is formed, and the process repeated until the desired result is attained.

The statement has been made that the criterion adopted (that of equality between the two probable errors) is incorrect, and a different one has been suggested, viz., that sufficient terms of the Fourier series should be included to make the probable error deduced therefrom a minimum. It seems to the writer, however, that a perusal of the preceding paragraph will establish the fact that his criterion is essentially logical and reasonable. The suggested criterion, not to mention the fact that it takes no account of the known accuracy of the observations (which can be measured independently), and that the whole principle involved in its application (that of "minimum probable error") is at least very seriously open to question, is manifestly entirely inapplicable in the present case. For it may be shown that in the attempt to represent any such observed series of quantities by a Fourier expansion, the computed probable error diminishes continually as the number of terms included increases; the proof of this theorem is elementary. Thus the adoption of this criterion would necessarily be synonymous with the use of a curve totally unsmoothed, that is, of the actual observed values.

It has been mentioned above that the use of the Fourier series amounts to drawing a smoothed curve in a particular way. It may be conceivable (though it does not appear in any way certain) that in some special case this particular way might not be suitable, i.e., that a limited Fourier series might not be applicable at all. This could probably occur only in the case of very irregular pivots, where the majority of the co-efficients in the complete Fourier series would be comparatively large. Even in this case the only fact that seems clear is that the number of terms necessary to give a satisfactory representation would be so large that the labor of computation would be prohibitive. In any case an examination of the residuals from the adopted curve will readily show whether any marked runs occur; if not the formula may be safely adopted. In the writer's judgment the occurrence of marked runs in the residuals would simply indicate that the pivots were decidedly irregular, and stood in need of re-grinding.

The actual determination of the pivot errors of the meridian circle at this observatory, referred to at the outset, was made by the microscopic method. Eight complete measurements of pivot errors were made; the probable error of a pair of microscope pointings (treated as a single observation) was found to be .0015 sec.; five cosine terms and five sine terms of the Fourier expansion (which may be combined into five cosine terms) were found to be sufficient to reduce the computed probable error to the same value. When the results are put in the form of a correction to the observed collimation it may be shown that terms involving the sine and cosine of the zenith distance have no effect; consequently these were omitted.

The resulting formula is:

$$\Delta c = {}^{s}.0010 \cos(2\theta - 188^\circ 29') + {}^{s}.0117 \cos(3\theta - 3^\circ 17') + {}^{s}.0021 \cos(4\theta - 59^\circ 45') + {}^{s}.0008 \cos(5\theta - 121^\circ 58')$$

* Appearing in the bi-monthly journal of the Royal Astronomical Society of Canada.

θ being the zenith distance. The residuals from the formula were satisfactorily small (in no case exceeding .002 sec.), and appeared to be purely accidental.

Values of the formula were computed for different zenith distances, and from these a table was prepared giving the zenith distances at which the value of Δc changed from one unit (in terms of .001 sec.) to the next; it is this table which is used in the reduction of transits.

It may be remarked that the strictly logical method of procedure would be to treat the sine and cosine terms independently. Thus, if the complete representation is given by

$$\Delta c = a_0 + a_1 \cos\theta + a_2 \cos 2\theta + a_3 \cos 3\theta + \ldots\ldots\ldots + b_1 \sin\theta + b_2 \sin 2\theta + b_3 \sin 3\theta + \ldots\ldots\ldots$$

the terms with largest coefficients should be chosen without combining the sine and cosine terms in pairs. This mode of procedure would in the actual case considered have changed the adopted formula slightly, in that the term involving sin 2θ (coefficient $-.0002$) would have been omitted, and that involving sin 12θ (coefficient $-.0005$) would probably have been included. Had the tables not been completed originally with the formula as given above, this change would have been made. As, however, the change in adopted pivot errors would have been extremely minute, it has not, up to the present at least, been thought worth while to make the change.

THE NEW DOCK AT SINGAPORE.

The completion of the King's Dock at Singapore marks an important stage in the scheme of extension and reconstruction works undertaken by the Singapore Harbor Board. The new dock is the largest dry dock in the far east. Its length from the outer stop to the head is 892 ft. 6 in., and from the inner stop to the head 876 ft.; the width at the entrance 100 ft., and inside the dock between the copings 128 ft.; and the depth on the outer sill 34 ft. at high water, and 24 ft. at extreme low water. By means of a central caisson the dock can be divided into an inner and an outer portion, 502 ft. and 346 ft. long, respectively.

With the exception of the entrances, which are of Cornish granite ashlar, the dock is constructed entirely of concrete. The altars consist of moulded concrete blocks, and the remainder of the face is of fine concrete masswork. Three rows of granite keel block courses run the length of the dock under a corresponding number of heavy timber keel blocks, the remainder of the floor being of mass concrete.

For filling the dock two culverts 7 ft. high by 4 ft. 6 in. wide are provided, and for emptying it there are two culverts measuring 10 ft. by 6 ft. The pumping station contains two Gwynnes' 60 in. centrifugal pumps; each has two suctions 36 in. in diameter, and they are together capable of emptying the dock, which contains 22 million gallons of water, in less than two hours against a maximum lift of 30 ft. Each of the pumps is direct coupled to a compound condensing engine of about 1,100 horse-power, having cylinders 24 in. and 46 in. in diameter with a stroke of 24 in. Steam is furnished at 160 lbs. pressure by three boilers, each able to evaporate 12,300 lbs. of water an hour.

Two ship caissons are provided, each weighing 826 tons, including ballast, and as they are identical in size they are interchangeable. Included in the equipment are four ten-ton and eight five-ton capstans, a five-ton crane, a fifteen ton crane and penstocks, all the appliances being worked electrically by power generated at the Board's own power station. The cost has been over $2,000,000.

SHELLFISH CONSERVATION AND SEWAGE DISPOSAL.

THE American Public Health Association has a committee on sewage collection and disposal which will submit a majority and minority report at the convention in Colorado Springs this week. The question of conservation of the shellfish industry is one reason for the lack of unanimous opinion on the part of the committee. In connection with this question Mr. George A. Johnson, consulting engineer, New York City, and a member of the committee, has favored us with a copy of his comments upon the present situation.

He outlines the reversal of conditions since the day when the aborigines made free use of shellfish as food. Since that time huge sewer outfalls in the neighborhood of shellfish grounds have greatly altered public opinion on the advisability of their use as a fish. The shellfish industry has grown until the value of the total annual output of nearly 40,000,000 bushels amounts to approximately $20,000,000. Where shellfish formerly grew in a naturally pure state the grounds are more or less subjected to currents of contaminated water.

Another point touched upon is the certainty of epidemics of typhoid fever and other disorders as a result of the use of polluted oysters for foods.

It is a problem how shellfish grounds may be protected from contamination from this source. The best grounds are found in the mouths of rivers and bays near the ocean, which is unfortunate, as such waters are usually subjected to pollution by the sewage of cities and towns located directly on or tributary to them. The report goes on to state that although shellfish in constantly changing, unpolluted water will become purified in from one to two weeks, this department of oyster purification has not been receiving adequate attention, although deserving of exhaustive study.

Another point is that shellfish will continue to be used as food, and that, "except in special well adapted cases it is impossible, on financial and other grounds, to conserve absolutely the purity of shellfish by sewage treatment. Complete treatment of the sewage entering waters which flow over shellfish layings will improve existing conditions, and in special cases almost, if indeed not entirely, remove the existing danger; but to be thoroughly effective a condition is required which is seldom, if ever, found at sewage treatment works to-day. There would be required not only extreme conscientiousness in the operation of the sewage treatment works, paralleling the vigilance with which good water filtration works are watched, but also interstate co-operation, the whole order of affairs being supervised by a supreme authority vested by law with power to approve or condemn.

"The conservation of the shellfish industry is a difficult problem, made so by the fact that common law rights of sewage disposal into the sea and its estuaries have been and are being extensively utilized. To set these conditions back a century solely for the sake of conserving the oyster industry, where no other offence is created, is a matter which, if pressed, will engage active sanitary, financial and legal minds for many years to come."

The new Canadian Northern road from Toronto to Ottawa will be opened about October 15th. The line is one of the main connecting links of the Canadian Northern Ontario lines, and will open a straight connection from Northern Ontario and Toronto to Montreal and Quebec.

THE EFFECT OF SATURATION ON THE STRENGTH OF CONCRETE.*

By J. L. Van Ornum, M. Am. Soc. C.E.
Professor of Civil Engineering, University of Washington

THE paucity of recorded information concerning the treatment of concrete specimens, with regard to moisture conditions during their storage while awaiting the test for strength, seems to indicate a general supposition that this feature has no considerable effect on results. Apparently corroborating this attitude is the statement in the recent report of the Special Committee on Concrete and Reinforced Concrete, in which, while specifying the exact dimensions, mixing, consistency, age, etc., of test specimens, the only requirement designed to control moisture treatment during their curing seems to be that they shall be "stored under laboratory conditions." It is the purpose of this paper to invite attention, not only to the great importance of specifying and standardizing the moisture treatment of specimens intended for testing, but also to the further fact that similar conditions, as they act on the finished structures, will affect their strength considerably, and therefore should be considered in specifying the proper unit stresses. It is evident that this factor should not be ignored when great variations in strength, to an amount of perhaps 50% above or below a mean value, result from differences in moisture conditions.

During the last six years this question, at times, has been the subject of investigation in the Washington University Testing Laboratory. Different features have been explored experimentally since 1907. Although these tests leave the greater part of the field still untouched, the results thus far obtained are so definite in their showing of a decided influence of moisture conditions on strength, and so significant in their general indications, as to authorize a summarized statement of experimental results to the engineering profession for its consideration.

The most important part of the investigation is that of the effect, on the compressive strength of concrete, produced by varying systematically the relative length of time of exposure in air and in water.

The test specimens were cylindrical, 8 in. in diameter and 16 in. high. The materials were: a standard brand of Portland cement which fulfilled thoroughly all the requirements of the standard specifications; a clean sand of good quality, weighing about 110 lb. per cu. ft. when dry, and having 36% voids; and a washed river gravel of the same weight, varying in diameter from quite small up to 1½ in., and having 33% voids. The proportions were the usual 1:2:4, by volume; the mixing was done thoroughly by hand; and the quantity of water used was such as to give a moderately wet consistency, which allowed a thorough compacting by stirring with an iron rod and a slight tamping. All details of fabrication, curing, and testing were planned so as to secure such complete uniformity as is practicable to obtain in all regards except the one for which the controlled variation formed the particular purpose of the experimental study.

The cylinders were removed from the moulds when two days old, and were tested at an age of six weeks. The intervening 40 days constituted the period in which the duration of their immersion in water was varied systematically from nothing to the full time. The average results of the 240 tests thus made are plotted on the diagram, Fig. 1, on which the abscissas represent that number of days (after the two days in the moulds and the time of exposure to air) during which each set of specimens was placed in water before crushing them; and the ordinates give the percentage of strength which each set of immersed cylinders (standing in water for the indicated number of days) was found to have, taking the compressive strength of the dry specimens from the same mix as 100 per cent. Thus, at the extreme left is represented the basis of comparison, or those which were not immersed at all; those specimens which were cured in air of ordinary humidity for 32 days and then immersed for 8 days are shown by the black circle to be 86% as strong as the air-cured concrete; those in air for 12 days and therefore finally cured in water for 28 days have gained 9% in strength; and those submerged for the entire 40 days exhibited an average compressive strength fully 50% greater than that of the air-cured specimens.

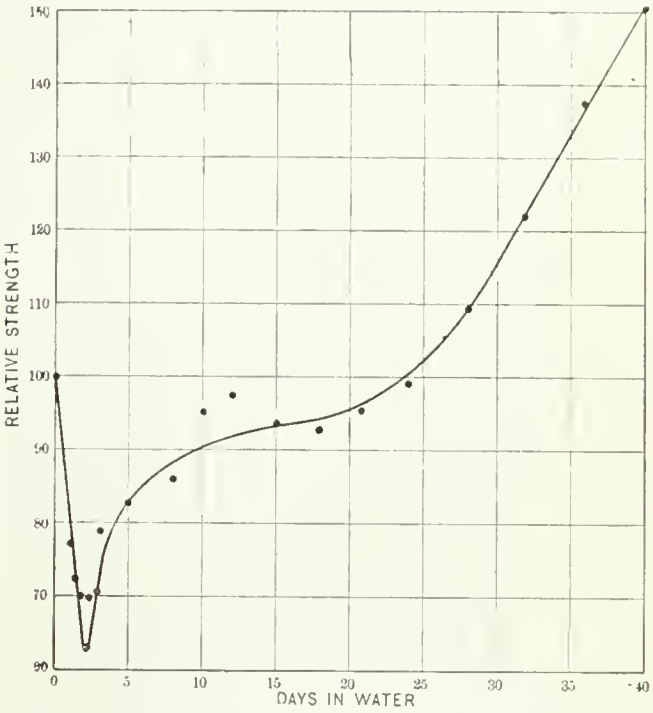

Fig. 1.

An average curve for the plotted points has been drawn as a full line, showing the systematic increase in strength as the time of submergence is lengthened beyond 2 days; but there exists the significant fact that specimens, of the dimensions used, decrease rapidly in strength when stored in air for 38 (or more) days and then placed in water for the remaining 2 days (or less). This particular feature of the rapid loss of strength on first exposure to water, and the active but slower recovery of strength as soaking continued, required a multiplication of tests to determine satisfactorily the locus of the curve in this region; and consequently more than half of the experiments were concentrated in this descending and the adjacent rising portion of the plot.

It thus appears that the compressive strength of concrete exposed only to air may be reduced nearly 40% when saturated with water, but that this loss is actively regained as the treatment is continued. The word saturation is used advisedly, because the minimum strength was found to coincide practically with the length of time required

*To be presented at the November 5th meeting of the American Society of Civil Engineers.

for water to penetrate to the middle of the specimens. Very plainly, this loss of strength has no relation to the percentage of contained moisture, as it is not only regained but much exceeded if the saturation is continued long enough. Perhaps the reduction in strength is purely a temporary physical phenomenon which is gradually counteracted and finally dominated by continued saturation permitting the imperfectly developed chemical processes of hardening to proceed actively. If this be true, concrete would regain something more than its original strength if dried out as soon as completely saturated, but this value would be less than that attainable by a continuance of the water treatment; also a repetition of soaking after such an experience would again temporarily reduce the strength, but less than before. These questions, as well as others, such as the duration of saturation necessary to prevent the temporary relapse of strength described, the corresponding effects of other periods of treatment similar to that discussed, of alternating the exposure to air and water, the result of different dimensions, proportions, materials, etc., all offer a large, interesting, and fruitful field for investigation.

In a series of experiments on the factors affecting the strength of bond between concrete and embedded steel, 74 tests were made to determine whether there existed the same tendency of rapid weakening at first and a following recovery of strength when the dry specimens were immersed in water. The concrete was of the same character as already described, and the test specimens were partly of the notched beam type transversely loaded, and partly of cylindrical form in which the rod was pulled from the embedding concrete. All care was used to make the methods of testing such as to minimize all variables except the particular one the effect of which was sought. The results indicate clearly, for both plain and deformed bars, that the bond strength values, similarly, decline rapidly and then increase after saturation is complete, as is the case with the compressive strength; although the average minimum observed was only about 75% of that of the specimens cured entirely in air. Whether or not this percentage really marks the greatest weakening of bond produced by immersion at an age of 6 weeks is somewhat uncertain; perhaps additional tests for intermediate periods of soaking would have developed a further reduction in strength. At any rate, a similar behavior characterizes the bond values obtained during the first few days of saturation.

Thirty-two beams were made of such dimensions and amount of longitudinal reinforcement (without any web reinforcement whatever) that failure would always occur through the effect of the excessive web tension in the concrete. The materials were of the same quality as those already described, and equal precautions were taken to secure reliable results. These beams were also tested at an age of 6 weeks, but the small number restricted the investigation to lengths of immersion designed to detect only the early loss of web tensile strength and its subsequent increasing value, without tracing it throughout successively lengthening periods of exposure to water to the limit of 40 days. The characteristic effect is again the same, the lowest average found being again practically three-fourths of the strength of the air-cured specimens. It may be that, in this case also, the minimum value was not detected.

A series of experiments on concrete prisms when 7 years old, to determine any change due to age in elastic properties, has been discussed previously by the writer. It may be stated, in reference thereto, that the modulus of elasticity of these old prisms exhibited a practically constant value throughout the repeated loadings equal to the maximum before found, which was about 80% greater than the final constant value as then reported for prisms of ordinary age; or a value of 4,000,000 in compression for that 1:3:5 limestone concrete. In these experiments two specimens were immersed in water until saturated and then carefully tested; the resulting compressive modulus of elasticity for wet concrete was 60% of that observed on the same specimens when dry. This lowering in value refers, again, only to the effect produced as soon as the saturation is complete and has no reference to a continuance of the exposure to water, such as is reported on certain other tests, where the figures given for the compressive modulus of elasticity of concrete specimens cured entirely in water for 26 days are about one-fourth greater than for those cured only in air.

As the various strength values of dry concrete are temporarily reduced from 25 to 40% by saturation, it would seem that this fact should be given definite consideration in fixing the working stresses used in the design of structures which may be thus exposed, or else conditions should be controlled in such a way as to prevent the weakening thus produced. No such effect occurs in concrete constantly under water or in moist earth from the time of its fabrication; but construction above ground, and therefore exposed to dry air for a time and then to a heavy rain or other source of rapid wetting, presents conditions under which this reduction in strength exists temporarily. Fortunately, the remedy is simple and inexpensive. It is to keep the exposed material thoroughly wet until its enclosure by exterior walls and roof renders its saturation by rain impossible. The case of parts not thus protected, or those for which enclosure is delayed, is not so simple; because the length of time of saturation which will make the concrete safe against serious reduction of strength is uncertain. The systematic wetting of concrete is a well-known principle of good construction; but the writer's observation and experience suggest a very considerable tendency to regard that procedure as abstractly correct, but practically rather specious or trivial. One purpose of this paper is to present the facts in such a way that the frequent, thorough, and faithful wetting of all parts of such concrete structures shall henceforth be no more ignored than is now the protection from freezing or disturbance while setting. Probably this treatment should be continued for a length of time substantially greater than that heretofore indicated—perhaps for a period expressed in weeks instead of days.

Undoubtedly, carelessness in a thorough control of this kind is a frequent contributing cause of weakness which is sometimes sufficient to result in failure. Very evidently, this temporary weakening of concrete by saturation is amply covered by the factor of safety required by good practice, if it be the only fault; but the materials may be considerably below standard, or the workmanship may be defective, or the design may encroach on the reserve of safety, or the occasional overload may be imposed; and if the material man, the construction superintendent, the designer, and the user of the structure should each rely on the others to meet fully the requirements, in the expectation that his own delinquency will be safely covered by the factor of safety, it would not require an impossible coincidence of such conditions to cause disaster; especially in view of the fact that considerable variations from the average strength values, which form the basis of design, necessarily exist in different parts of the structure. In fact, the failures which have occurred are

generally a result of several such contributing causes. The writer believes that the considerable weakening produced by the saturation of dry concrete has invariably been a contributing factor in all those instances in which there was an active wetting of dry or partly dry concrete when subjected to essential stresses.

This general proposition furnishes one more evidence of the remarkable responsiveness of concrete to variations in its treatment. The fact that differences in control (which to the average artisan are seemingly unimportant) actually do exert a positive influence on its essential characteristics, constitute a definite warning against entrusting it to the uncertainties of irresponsible or skeptical supervision, and assures ample reward for a competent control which is correctly adapted to develop its capabilities. The susceptibility of steel to the influence of phosphorus and sulphur, of details of its heat treatment, and of other conditions occurring in the process of its manufacture, have resulted in restricting its production to the scrutiny of expert superintendence. Equal reason exists for, and commensurate advantages will follow, a thoroughly discriminating control of both the initial fabrication of concrete, and the details of treatment during its hardening, in order to realize the great possibilities inherent in this newer material.

The treatment of steel is not always complete as it comes from the rolls, as is shown by such effects as the changes in strength produced by the cold-twisting of steel rods; much more important in relation to the resulting quality of concrete is the nature of its treatment after fabrication, both because its attainment of strength is a relatively slow process and for the reason that the nature of the prevailing conditions provided during this period affects so greatly the development of its essential properties.

The notable responsiveness of concrete to the character of its treatment is a direct appeal for thoroughly trustworthy and expert control.

WATERPROOF CONCRETE.

In connection with preparations for the construction of a new lighthouse in Germany, some interesting experiments were carried out in the direction of waterproofing concrete. Various mixtures of cement and fine sand, in ratios of from 1 to 1 to 1 to 6, and mixtures of 1 to 3, with the addition of various materials, as soft soap, were moulded into pot-shaped vessels about 15 in. high with 2½ in. walls. When these pots had set, some of them were filled with water and others, empty, were placed in water, and the density of the walls was judged by noting the time required to empty or fill, the water acting under a maximum head of about 10 in. It is curious to note that a satisfactory degree of imperviousness was not reached, since in every test the vessels emptied or filled within one hour. The relative success of the richest mixtures then induced tests of rich-rubbed surfacing. To this end the surfaces were first wetted, then thickly coated with cement paste, and with a soft brush the cement was rubbed well into the surface of the concrete. This procedure was repeated a number of times, until the pores were closed, and a satisfactory degree of imperviousness was then reached, as the pressure tests, continued for three days, showed that no water penetrated through the walls of the pot. It was the success of this method that decided the authorities upon building the lighthouse of concrete made impervious in the manner outlined above.

A RATIONAL FORMULA FOR ASPHALT STREET SURFACES.*

By J. Alden Griffin, Assoc. M. Am. Soc. C.E.

EVERY now and then the question is raised: "What is the proper crown to give an asphalt street?" and there is a discussion as to which of the many formulas of to-day gives the best results.

Having been asked this question many times in the past few years, and especially while connected with municipal improvements in Los Angeles, Cal., the writer has given the matter careful investigation, and, by a comparison of the surfaces proposed by the various formulas, has arrived at the conclusion that the crown rise should vary with the cross-fall as well as the grade of the roadway, and that a crown considerably lower than that proposed by the well-known formula of the late Andrew Rosewater, M.Am.Soc.C.E., should be used on streets having a cross-fall between the gutter grades. The writer even favors one which is slightly lower, where there is no cross-fall in the roadway; and, having reached these conclusions, he proceeded to determine the proper amount of reduction to make in the crown for varying cross-falls. After a great many experiments he adopted the following modification of Mr. Rosewater's formula. This gives the best results, using one-eighth of the cross-fall plus ¾ in. as the reduction factor, but some may wish to change $0.12H$ in the formula to $0.10H$, or even $0.08H$, in order not to reduce the crown quite so much; however, the following is recommended:

$$C = \frac{W\,(100 - 4\,p)}{5{,}000} - (0.12H + 0.06)$$

in which W = the width of the roadway between curbs, in feet; p = the percentage of grade longitudinally on the street; H = the cross-fall of the street, or the difference of elevation between the high and low gutters, in feet,

TABLE 1.

*From Proceedings Am. Soc. C.E., for August, 1913.

and C = the height of the crown above the mean gutter grade, in feet.

It will be noticed that on a roadway having a very steep cross-fall the upper gutter will not hold water, which, in the majority of such extreme cases, will do no harm, and will very often save a cross-gutter at the intersection; however, it may be desired at some time to hold the water in the upper gutter, and this may be accomplished, without increasing the side slope of the surface, by shifting the crown to the upper side of the centre of the roadway as shown in Fig. 4, which indicates a special cross-section at that point.

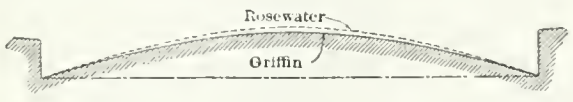

FIG.1

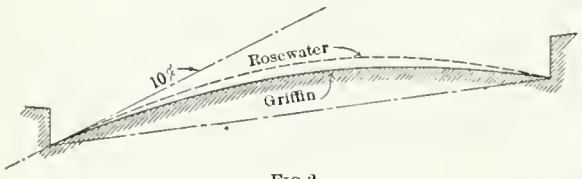

FIG.2.

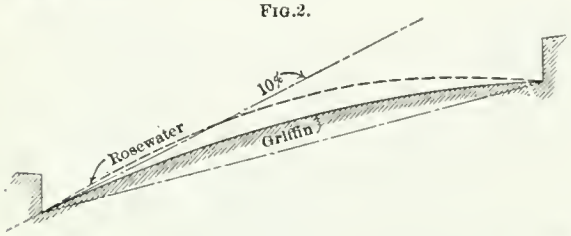

FIG.3.

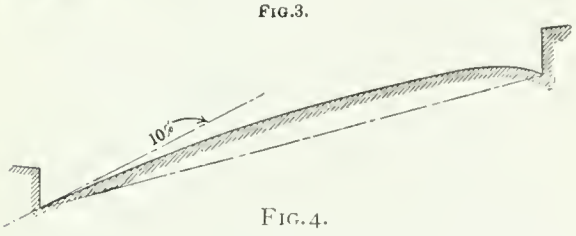

FIG.4.

Table 1 is compiled from the formula for the more common roadway widths in Los Angeles.

Figs. 1 to 4 illustrate the comparison between Mr. Rosewater's formula and the modification herein proposed on a 40-ft. roadway having a 1% grade. Fig. 1 is for no cross-fall; Fig. 2 for a cross-fall of 1 ft. between the mean gutters, and Fig. 3 is an extreme case with a cross-fall of 2 ft. between the mean gutters. Fig. 4 illustrates a section in which the lower half meets the formula and the upper half is modified to hold the water in the upper gutter.

A new building material, known as "Tekton," which is being introduced in Glasgow, is stated to be of the nature of artificial wood and to possess the strength and durability of concrete. The ingredients of which the material is formed are magnesite, granulated slag, chloride of magnesium, and "wood flour," and its principal properties are that it is porous, has a low heat conductivity, and is sound-proof, fire-resisting, odorless, and not liable to develop dry-rot. It is made in boards and planks, or it may be modelled in any required shape. It is claimed to be particularly suitable for use in the construction of portable buildings which have to be erected rapidly and cheaply.

RAILWAY EFFICIENCY.*

By Mr. A. Crumpton,
Assistant Engineer, Grand Trunk Railway, Montreal.

THE product of a railway is transportation, and the measure of its efficiency is the quality and cost of producing the same. In transportation upon land the railway has proven itself pre-eminently superior to any other way. It is a far cry from a rate of $1 per ton per mile for "packing" upon men's backs, or even 25c. per ton mile by team, to ¾c. per ton mile, which is the average cost to the public by railways in America. Passengers in America pay an average charge of a little less than 2c. per mile, and a trip of 500 miles in 12 hours is common. Only the man on the inside realizes what this means, both as regards perfection and economy of construction and operation.

In Europe the average freight charge per ton mile is 1½c.—double what it is in America—while passenger rates run from 1¾c. to 2c. for third-class to 3c. to 4c. for first-class accommodation. This is only of interest as showing where we stand, but does not prove anything as regards relative efficiency, the conditions of construction and operation being different on the two continents.

In 1870, the average freight rate per ton mile was 2c. as against ¾c. in 1909, a reduction in 40 years of 62%.

Mr. W. M. Acworth, an international authority on railway economics, who from time to time inspects American railways in the interests of English investors, says: "It has been my opinion that in actual economy of operation the railways of the United States are first in the world."

A railway to continue and increase its efficiency must not only keep up its lines and equipment for current traffic, but must have means in advance to provide for increasing requirements. This country is rapidly growing in population and wealth, and there is an insistent demand for a better and more improved passenger service, faster freight service, and greater safety. Since these things, speaking generally, do not increase revenue they are a proper charge against operating expenses, and should be met by increased rates for transportation, where necessary. The peculiar fact is that while the public appreciates the situation in ordinary matters and expects to pay more for better pavements or better clothes, yet, in matters of transportation it demands better service but refuses to pay more for it.

When, in 1910, a large section of the railways of the United States made application to the Interstate Commerce Commission for authority to increase rates, they were met by statements alleging lack of scientific management—that a million dollars a day could be saved by increased efficiency—and their request was refused.

Detailed records of cost of building and maintaining railways and of conducting transportation have now to be kept by the railways, at the instance of the commission, and the appraisal of all the railways in the United States has just been ordered, so that, no doubt, any future question of rates will be dealt with in the light of the efficiency shown by the railways.

Briefly, it is claimed that the railways fail in efficiency as follows:

*Read before the Canadian Railway Club, September 9th, 1913.

(1) Maintenance of equipment, which consumes about 20% of total operating expenses.

"Railroad repair shops throughout the country do not show 50% efficiency on an average as regards either materials or labor."—Emerson.

(2) Maintenance of way, consuming about 20% of total operating expenses.

"Standards of maintenance of way vary, but innumerable assays of actual work show a maintenance-of-way labor efficiency of scarcely more than 30%."—Emerson.

(3) Transportation, consuming about 50% of total operating expenses.

"Fuel.—On the Santa Fe average fuel used per 1,000 freight train ton miles was reduced from 261 lbs. to 239 lbs. On the Chicago, Milwaukee & St. Paul, 175 lbs. Dynamometer Car, 80 lbs."—Emerson.

"It has been demonstrated that by proper instruction, fuel consumption could be reduced at least one-half."—Brandeis.

Terminal expense, particularly the handling of less than car load lots, should be improved by the use of mechanical conveyers.

Maintenance of Equipment.—A fair comparison cannot be made between industrial shops with uniform output and railway repair shops with little uniform work, particularly as such repair work is incidental to the main purpose of producing transportation, and while low cost is desired, expedition is primarily which is required.

Maintenance of Way.—The fact that maintenance-of-way forces may be scattered over thousands of miles of line makes adequate supervision difficult, and that the labor requirements vary with the season makes it impossible to always have the force as efficient as could be desired. The force required to man a thousand miles of line could be concentrated on one acre in a textile mill, so that comparisons of efficiency made under such conditions would be unsatisfactory.

Transportation.—Transportation forces are strongly organized and militant, largely increasing the difficulty of reducing labor charges, but by betterment of roadway and the use of heavier power the railways are effecting such economies as are possible. In this connection Mr. Emerson said: "The efficiency of the traffic by my standards is very high; that is, the efficiency of expense in the traffic departments."

As regards economy in fuel and in its use, this has ever been a subject of investigation on the part of the railways, as also that of mechanical conveyance.

It may also be said that railway development has been proceeding along logical lines. First, the period of railway building, then one of traffic organization and consolidation, followed by one of betterments, embracing perfecting of machinery, strengthening roadbed and bridges, cutting down grades and increasing the motive power and weight of trains. Now the human factor is coming in for increased attention and systems of organization are being studied to the end that the machine as a whole may be brought to the highest efficiency.

In this connection it will be interesting to examine the fundamental principles of scientific management as given by Mr. Frederick W. Taylor, its originator:

"1st.—Each man in the establishment, high or low, should daily have a clearly defined task laid out before him. This task should not in the least degree be vague or indefinite, but should be circumscribed carefully and completely, and should not be easy to accomplish.

"2nd.—Each man's task should call for a full day's work, and, at the same time, the workman should be given such conditions and such appliances as will enable him to accomplish his task with certainty.

"3rd.—He should be sure of large pay when he accomplishes his task.

"4th.—When he fails he should be sure that sooner or later he will be the loser by it.

"When an establishment has reached an advanced state of organization, in many cases a fifth element should be added, namely, the task should be made so difficult that it can only be accomplished by a first-class man."

The railway as a proposition is characterized by its great extent requiring unusual specialization in every branch and this has in the earlier days led to undue centralization and the creation of departments whose heads endeavored to perform both "staff" and "line" duties. A departmental organization of this kind, projected over large areas with distant headquarters, has proved cumbersome in operation, a breeder of departmental jealousies, and unsatisfactory to both the public and employees. This type of organization is now being superseded by one in which the "staff" and "line" functions are being separated. "Staff" functions, consisting largely of the theoretical side of the work, studying the underlying principles, whether physical or psychological, which make for efficiency in construction and operation; systematizing and standardizing every operation; providing instruction as to application and formulating means by inspection and otherwise for unerringly recording attainment, is necessarily the work of specialists.

Line functions, consisting of the more practical side of the active conducting and directing of the work is none the less the work of specialists and experts, but of execution rather than design.

Line officers are in charge of stated districts, representing the railway in general and not any particular department. Under this arrangement the different departmental activities are co-ordinated and all the advantages of the public and employees being brought into close touch with a responsible representative of the railway gained.

In line with this, the accounting for each district is done on that district, to the end that greater accuracy may be attained by first-hand knowledge and the officer in charge of the district be in possession of all the figures pertaining to the work for which he is responsible, thus enabling him to supervise more intelligently.

A further development follows—that is a common office and file. While merely a detail, this has proved of great value in reducing the volume of correspondence and locating upon one file everything that pertains to any given subject. The use of this system on the railways recently known as the Harriman lines saved half a million letters a year.

Since material as well as labor enters into the work of a district, it is logical that this, both as regards purchase and supply, should be as far as possible in the hands of the local man, in order that he may be informed on every point. In the larger matters, blanket contracts would be let and districts would simply order under these, while in minor matters, standard prices would be fixed and when goods could be purchased locally as cheaply, preference would be given to the district, thus decreasing handling and increasing the good-will of the local public.

The distribution of the prime functions of railway building and operation would be:

Headquarters.—Building of railway; construction of equipment; creating standards for conducting transportation, and for maintenance of roadway and equipment, as well as for the necessary instruction and inspection.

District.—Conducting transportation; maintenance of roadway; maintenance of equipment.

A superintendent with a staff expert in the above-mentioned lines, and first-hand knowledge through his accountant of actual costs to compare with standard costs, both of labor and material, would at all times know the relative efficiency of his district.

The strong feature of this type of organization is that with reasonable standards of work to be performed, everybody concerned from start to finish has something by which to measure his work. A New York contractor, as an experiment, arranged for each man to have a bucket to shovel into. Result—almost at once the number of buckets that came out of the hole was doubled.

The creation of standard practice, both as regards methods and cost, is merely an elaboration and extension to every operation of practice now in vogue on all railways. For example: it is decided to bring a line up to a certain standard. Careful account is taken of what exists, then the method of producing the desired result is determined, written instructions are given and the cost calculated. Or a new train service is to be put on. Its requirements are determined, time tables prepared and its cost calculated.

Working to standards throws into prominence any over-running of standard costs, and this acts automatically, and those in immediate charge of work look into the cause and remove it if possible, and if unavoidable keep proper records of its nature, for the creation of a new standard, if necessary.

Increasing Efficiency.—Efficiency experts have placed railway efficiency at 70% as against 60% in industrial concerns generally. While the total elimination of waste is impossible, certain classes of work have on many roads reached a much greater efficiency than the above average.

The first step should be to ascertain, tabulate and analyze present practice with particular reference to unit cost of performance. In most cases this could be done with little or no additional expense, simply the introduction of forms designed to this end in place of those now in use. The knowledge so obtained would be a basis from which to work, in fact, could be used as a standard of measurement pending the introduction of proper efficiency standards. Concurrently, present standard practice, as ascertained on one road should be compared with standard practice on other roads or elsewhere, and when a superior method is found it should be adopted. Plans should be made, written instructions prepared of every step of the operation, not only what is to be done but how, and a standard of cost provided.

The following is an example from shop practice: Mr. Emerson went to the Santa Fe and found the annual cost of maintaining belting was 100% of its first cost. From previous experience he knew that this figure should be about 14%. Having this to work on, the best belting obtainable was purchased, 5% above the market price being paid for the privilege of rejecting unsatisfactory belting. A man was put in charge of the belting with instructions that belts were to be kept in condition and replaced before and not after failure. Results—failures reduced from 300 a month to 50 and cost dropped from 100% to 14%. Incidentally machines were not delayed.

In the creation of standards details down to the tool or machine to be used for a given service are specified. For example, in section work the relative economy of hand cars and motor cars is ascertained. Cars are then studied, improved and standardized, and under given conditions, which is to be used is specified.

The following are a number of instances of increased efficiency given before the Interstate Commission:

1. When applied to the simple operation of loading by hand a railroad car with pig iron, the performance of the individual worker increased from 12½ to 47 tons per day.

2. When applied to shovelling coal, it doubled or trebled the performance of the shoveller.

3. When applied to machine work, it developed in certain operations, increases in production, ranging from 400 to 1,800 per cent.

4. When applied to bricklaying, the day's accomplishment rose from 1,000 to 2,700 bricks.

It should be borne in mind that in dealing with this side of the question that a representative of railway labor appeared before the commission and stated that the methods referred to could not and should not be introduced into railway work. In like manner the introduction of the Mallet Compound locomotive was strongly resisted by the Brotherhood of Locomotive Engineers, and organized efforts were made by conductors and trainmen to have double-heading prohibited. The fact is that labor organizations, notwithstanding the good which they have accomplished, are, as at present constituted, by their very nature, detrimental to efficiency. Employees in their respective classes are allied with like classes on other railways, for the furtherance of their particular class interest, and where this interest demands it, the interests and rights of fellow-employees, the public and the owners are made subordinate to their own. With the railway the tendency is to make the standard the pace of the fastest while with the union it is towards that of the slowest. The reasonable standard is somewhere between these extremes and should be scientifically determined, both as regards performance and remuneration, and the present system of highly organized labor holding a pistol at the head of the railways, to the detriment of classes less highly organized should be abolished. It would not be easy and would take much time, but it is conceivable that with a scientifically arranged and, therefore, equitable schedule of wages covering every branch of railway service, the settlement of schedules would become a matter peculiar to each railway and not determined by conditions on other railways having no bearing on the case. Such an arrangement would at least be an effort to give a "square deal" to all classes of employees.

As showing the way how not to create standards I quote the following from "Scientific Management of Railways," by W. J. Cunningham:

"The year 1910 saw the successful culmination of an ambitious plan to 'standardize' the wages of conductors, trainmen, and yardmen in the Eastern States; that is, to set a uniform rate per day, per hour, or per mile for each class of service, regardless of local conditions. The road with the highest wage scale (the Baltimore & Ohio) was selected as the battle ground, and the entire forces of the train-service brotherhoods focused upon it in a demand for new and unreasonably high rates. To prevent a strike the railroad invoked the aid of the Board of Mediation under the Erdman Act, and the award, while not granting the rates demanded, carried with it substantial increases over rates already considerably higher than those of other

roads in the East with distinctly different operating characteristics. The new basis was then in turn forced upon practically every road in eastern territory. The increases in New England averaged between 20 and 30 per cent., and in some cases exceeded 50 per cent. At the same time long standing differentials between different grades of employees were seriously disturbed. Throughout, the new wage basis and working rules (prescribed partly by governmental mediation) are far from scientific or equitable."

Cost keeping must be systematized with the same care as other operations and be beyond criticism to be effective. The old saying that there are "lies, d—— lies and statistics" had its origin, no doubt, in poor cost-keeping. There is a story told of a locomotive standing in the shop waiting for small repairs where costs were carefully (?) kept and everything had to be charged. The old locomotive came in for all doubtful and odd charges until, at the end of three months, it had $5,000 charged against it.

If time is wasted it should be known as surely as if material is wasted and should be considered a reflection upon the system rather than upon the individual. The trouble is that where standards are lax there is an uncertainty as to where such waste is taking place, and advantage is taken of this to let the matter go.

Cost-keeping as above is becoming necessary to comply with the requirements of the Interstate Commission.

The phase of the situation which is the peculiar problem of to-day—that is, the bringing of the human factor in the machine up to standard—is first and last a matter of men, the production of highly trained men, for however efficient in design an organization may be, its real efficiency is measured largely by the human element. Unfortunately, under present conditions, a man enters railway life at the point of least resistance and gets where he can by force of circumstances and native wit. The result is that thousands of men are struggling to hold positions for which by nature they are largely unfitttd. For certain railway positions men are specially selected, the unfitted being rejected. Why should this not be the case for all? For practically every class of material used specifications have to be complied with, and a certain standard attained to be accepted. Why should this not be the case with men? Psychology has made such strides that it is conceivable that a bureau for the purpose could, after some experience, pass upon all applicants, and after deciding upon their general fitness or unfitness for railway work, guide as to the particular class of work for which they are best adapted. Inefficiency under present conditions is often as much a matter of circumstances as any fault of the individual.

When once accepted for railway service a boy or man should have definitely placed before him the necessity for qualifying for the position ahead, and failure to respond should be taken as an indication of unfitness for his particular work or lack of ambition, and the case should be dealt with accordingly. Vocational training has many enthusiastic advocates among railway officers, and is more or less the practice on some of our large systems, so that the material is not wanting for the elaboration of this idea.

The intelligent application of the principles briefly outlined above was the means by which the German army became well nigh invincible, and the nation has in a generation by scientific administration and rational educational training of its people, notwithstanding the poverty of its natural resources, passed from inefficiency to the front rank among the nations of the world.

The nucleus of the foregoing exists on the railways as operated to-day and all that is needed is that present practice should be brought up to date to meet expanding needs, and more thoroughly understood by all concerned. Speaking generally, what we need is a better understanding between head and hand, the proper blending of theory and practice; the creation of a feeling down to the last man that the railway interests are his and that in furthering its interests he is furthering his own.

THE WATER SUPPLY OF PARIS.

THE city of Paris is supplied with water from many different sources, and the distribution of the supply is under the control of several separate companies, and in part only by a committee of the municipality. Samples of the water from each of the supplies are taken each week and examined chemically and bacteriologically at the municipal laboratory at Montsouris, by Mr. F. Diénert, the official chemist and bacteriologist to the city of Paris. The results are published from time to time in the official municipal bulletin of the city. The bacteriological results, for a period of six months, from September, 1912, to March, 1913, as recently published in Engineering, London, are set forth in Table I. from which a comparison of the results obtained by the various systems of water purification may be made.

In the case of the four large service reservoirs at Paris, supplied respectively by aqueducts from the rivers Marne, Loing, Dhuis, and Avre, it will be noted that the bacteriological results are extremely variable, depending to a large extent on the rainfall and consequent state of each river. With regard to the filtered water supplies, the following is a brief summary of the systems employed at the various works.

At Choisy-le-Roi the raw water of the Seine is first passed through Anderson revolving purifiers, by means of which a certain quantity of ferrous oxide of iron is taken out by the water as it flows through. This iron is precipitated as ferric oxide in labyrinth settling-tanks—that is to say, decanting basins—through which the water is made to flow in a continuous stream by means of baffle-walls from inlet to outlet. Recently, however, this system has been partly abandoned, and one-half of the labyrinth settling-tanks have been transformed into roughing-filters, after which the water passes to ordinary sand filters. The roughing filters are scraped by means of the Boistel automatic machine.

At Neuilly the water of the Marne is treated by the ordinary system of decanting-basins and sand filters. At Nogent-sur-Marne decanting-basins, roughing-filters, and slow sand filters are employed. At Ivry Puech "degrossisseurs" were installed some 14 years ago, but the water passes direct from these on to slow filters, instead of being passed through coarse-sand pre-filters in series between the degrossisseurs and sand filters, as in the case of more modern installations on the Puech-Chabal system. At St. Maur, roughing-filters of the ordinary type are employed previous to slow sand filtration, after which the water of the Marne is passed through ozone sterilizers.

TABLE II.—SUMMARY OF RESULTS AT FILTERING STATIONS.

Total Bacteria per Cubic Centimetre after an Incubation of Fifteen Days.

—	Average.	Highest.	Lowest.
Choisy-le-Roi, (Seine)—			
Raw water	34,711	126,600	5,070
Filtered water	544	2,015	27
Neuilly, (Marne)—			
Raw water	30,249	120,250	400
Filtered water	288	1,084	17
Nogent-sur-Marne, (Marne)—			
Raw water	11,041	36,720	300
Filtered water	726	4,115	10
Ivry, (Seine)—			
Raw water	39,070	148,350	580
Filtered water	96	270	28
St. Maur, (Maine)—			
Raw water	21,434	47,200	700
Filtered water	278	1,620	10
Ozone sterilizers	42	249	0
Supply mains	352	1,190	80
Suresnes, (Seine)—			
Raw water	53,533	144,300	4,500
Filtered water, (mains) .	33	82	6

All of the above filtering stations draw their supplies from the Marne or Seine above Paris. At Suresnes the raw water of the Seine is drawn from the river after it has received the refuse from the city. It is pumped to the filtering station on Mont Valerien, where it is treated by a complete modern plant of multiple filters on the Puech-Chabal system., consisting of four series of degrossisseurs, coarse-sand pre-filters, and final slow sand filters. The pre-filters and sand filters are all fitted with automatic regulators.

The summary of the results, given in Table II., clearly shows that the more elaborate the filtration plant the more regular are the bacteriological results; and although at Suresnes the raw water contains a far higher number of bacteria per cubic centimetre than at any other filtration station, the results are extremely regular, the highest figure recorded in the final filtrate being 82 per C.C.; the average 33 per C.C., and the lowest 6 per C.C.

The samples at Suresnes are drawn from the supply mains after the water has been stored for about two days in the service reservoirs. At St. Maur it is curious to note that while the sterilizers occasionally eliminate all the bacteria, these appear again in the supply mains, after the operation of sterilizing, in apparently higher numbers than those found in the filtered water before sterilizing.

At Ivry a sterilizing installation on the ultra-violet-ray system has recently been installed; and it will be interesting to note in a future summary of the bacteriological results, whether the bacteria are augmented in this case also after sterilization. Unless filtration is carried out with a due regard to the time necessary for nitrification, the effluent is frequently too highly charged with organic matters in solution, and a possible explanation is that the bacteria afterwards found in this water are nitrifying bacteria, which would naturally multiply rapidly until they had fulfilled their function of mineralizing the organic matters in solution. It should be stated that the whole of the figures in the table are obtained by the French system of counting the colonies after an interval of 15 days.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, RAILROAD, MINING, MUNICIPAL, HYDRAULIC, HIGHWAY AND CONSULTING ENGINEERS, SURVEYORS, WATERWORKS SUPERINTENDENTS AND ENGINEERING-CONTRACTORS.

Present Terms of Subscription, payable in advance

Postpaid to any address in the Postal Union:

THE ROAD CONGRESS IN DETROIT.

Now that Canada has fully entered upon a new era of road development whereby the introduction of heavier, faster and more numerous traffic will be met by the adoption of more scientific methods in road engineering, Canadian municipal and highway engineers should come forward with keener desires for closer relations with those in the van of highway engineering throughout the world. It was not the good fortune of many to have been able to attend the London Congress in June. Doubtless the substantial gain therefrom in acquiring a fund of information of utmost practical value to them in their work would have vindicated the sacrifice of time and duties, had not such factors so strongly asserted themselves at that stage of the summer. From those who did attend Canada hopes to acquire many improved ideas, of practical value.

The Canadian Engineer has several times, of late, called the attention of its readers to the Third American Road Congress, Sept. 29th to Oct. 4th, in Detroit. The official programme appeared in Sept. 4th issue. No phase of highway work seems to have escaped the designs of the committee responsible for the programme, and the coterie of speakers is a substantial inducement in itself.

The educational advantages of the Congress should be grasped by Canadian municipal authorities. Many municipalities are not content with traffic conditions, and, while on the lookout for the essentials of better construction, their officials should not overlook the Detroit meeting, where papers and discussions will provide them with the brand of information which they find to be indispensible. Considering the enthusiasm which is being put into the movement for better Canadian roads, and the value that the Third American Road Congress will prove itself to be in this respect, a good representation of Canadian highway and municipal engineers should be in evidence.

EDMONTON'S WATERWORKS PROBLEM.

Like many another city, Edmonton has before it an acute problem in the acquiring of a better and a greater water supply. The question has been under heavy fire during the past year. Like many a western city, also, geographical and other conditions forbid placing material reliance, toward a solution, upon the designs carried out in the older and slower-growing cities of the East. The application of engineering skill must be direct. A thorough conception of principles underlying water service, blended by an exhaustive knowledge of all contingent conditions of the past and present, and a judicious forecast for the future, makes it a problem that only highly qualified engineers may be relied upon to handle. A water problem for a city differs from city planning, street paving, transportation, and others prominent in the category of municipal affairs, in that it has such a direct bearing upon life and health. It thereby maintains a degree of importance calling for the best, whether or not the attached expenditure is away and beyond comparison with that for other municipal works. Water supply is the chief contender for the most expert attention and advice in any municipality.

Edmonton is certainly not exempt from difficulties in the way of a pure supply, and the civic authorities are fully awake to the acuteness of the situation. The Saskatchewan River, the only feasible source, flows directly through the city, and its water is subject to dangers of

pollution from various causes. Again, the growth of the city has been phenomenal. From a town of about 2,600 in 1901, it has grown into a city with a population approximating 67,000, practically doubling its number of citizens every four years. Indications point to continued development, wherein lies a weighty and perplexing problem for the engineer who sets about to design systems for the requirements of future years. The average life-time which considerable portions of such a system may attain is 30 or 40 years. It need hardly be wondered at, that there are radical differences, at times, in the opinions of highly competent engineers, in their endeavors to find the best solution to problems such as Edmonton's. One point is clear: an adequate and consistently pure supply of water in the service mains commands superiority over antagonistic factors of speedy installation, low first cost, low operating costs, etc. In the consideration of the reports now in its possession, the city of Edmonton should keep constantly in the foreground the desirability of establishing a system that will provide such a supply; that may be extended as the city grows without unnecessary scrapping of plant before its day of usefulness has expired; and that will not be lacking in efficiency throughout its life-time, as a result of curtailment of initial expenditure with an aim at economy. For it must be acknowledged that, owing to the indefiniteness of the city's needs twenty or even ten years hence, the most careful aim at true economy in the construction and operation of the system may fall very widely off the mark. It remains, therefore, to make now the safest selection of source; then choice of the best site, and economic factors may enter the problem. Indefiniteness of future requirements makes the latter subsidiary to the former.

A NEW TRAIN CONTROL.

Mr. F. W. Prentiss, of Toronto, recently conducted a very successful demonstration of the Prentiss system of automatic "wireless" train control, of which he is the inventor, at the Hampton Court Station of the London and South Western Railway (England). In this system the track is divided into a number of insulated sections, in each of which a low-voltage track circuit is arranged, with, in addition, a high-tension wave wire running between the rails. At the end of each section is a box containing the high-frequency plant for the supply of current at 20,000 volts to the wave wire. This plant is controlled by a relay in connection with the track circuit of the section ahead, with the result that if that track circuit be short circuited the controlling relay is de-energized, and the supply of high-tension current to the wave wire ceases. The locomotive is fitted underneath with an arrangement of wires equivalent to the antennæ of the ordinary wireless apparatus. These receive the energy transmitted from the wave wire, and by means of a system of coherers and relays in the cab a green "line-clear" signal is provided for the driver if the section ahead is unoccupied. If, however, the section ahead be short circuited the wave discharge ceases, and a red light is shown and a buzzer simultaneously sounded, while the brake is at the same time applied, these operations being effected by power obtained from a battery in the cab. Provision is made to enable the driver to release his brake, but the red light and the buzzer continue until the section ahead is cleared, when the high frequency supply is re-established and normal working is resumed. The system, therefore, provides for a continuous danger signal on the locomotive so long as the line is not clear, the automatic application of the brake and a prompt intimation of the restoration of line clear conditions. In the event of failure of the high-tension, or the track circuit danger indications would be given. The operation of the cab apparatus naturally depends on uninterrupted battery supply. The demonstration was quite successful, the train being brought up on every trial by the automatically applied brake, although the regulator was untouched. The system requires electrical supply to all the section-boxes, and transformer plant in each section-box, in addition to the boxed-in high-tension wire between the rails and the apparatus on the engine. The expense question is therefore one which will have to be seriously considered before the system is likely to be largely adopted. In addition to initial cost the working cost must also be taken into account, the power taken by a half-mile section being about 1 horse-power.

COST OF WOOD BLOCK PAVEMENT.

In an article on street and pavement construction, which was published in our issue of September 4th, 1913, the following paragraph appeared on page 410:—

"In Hamilton this pavement (creosoted wood block) has become so popular that some residential streets have petitioned for it on account of its quietness; although it is a costly pavement, running from $2.25 to $2.65 per square yard, according to the kind of block, whether plain or grooved for heavy grades. All of these pavements have assumed a concrete base 6 in. thick at least on business streets, with a mixture not less than 1:3:6, which will cost from 50 cents to 60 cents per square yard."

Some readers are evidently under the impression that the city engineer of Hamilton, who was the author of the above article, meant that the cost of the foundation was included in the "$2.25 to $2.65." This is not the intended meaning. The cost of the foundation is extra, and the wood block is estimated by Mr. Macallum to cost from $2.25 to $2.65 per square yard, assuming that it is to be laid on a good concrete foundation.

In this article also the second paragraph of the second column of page 409 refers to "a temperature not less than 28%," where "28° F." was intended.

For the equipment of the two new battleships now being built at the Government dockyards of Lorient a crane of the Goliath type has been put in service, able to deal with a load of 150 tons, divided between two parallel travelling crabs of 75 tons, which can work separately or simultaneously. The crane consists of an inner framework or tower, surmounted by a platform which supports a cast-steel roller path, and of an outer slewing framework carried on the supporting tower. The lower part of the outer framework is fitted with rollers running on the roller path, which is of 14m. outside diameter. The jib has a total length of 70m., and is composed of lattice girders spaced 6.40m. from centre to centre. The crane has a maximum radius of 23m. with 150 tons and 30m. with 75 tons; a lifting speed of 1.50m. a minute with 150 tons, or unloaded of 4m. a minute; and a speed of horizontal motion of 8m. a minute with 150 tons. The upper part of the jib is fitted with a runway on which travels an auxiliary crane of 20 tons, designed with a lifting height of 60m. and a lifting speed of 10m. per minute (loaded). The crane has been successfully tested with a load of 180 tons at 23m. radius and with 90 tons at 30m. radius.

THE WATER SUPPLY OF EDMONTON, ALTA.

A DESCRIPTION OF THE PRESENT SYSTEM—SOURCE OF SUPPLY UNDER DISCUSSION — IMMEDIATE EXTENSIONS NECESSARY—RECOMMENDATIONS AND ESTIMATED COSTS*

THE water supply for the north side of Edmonton is drawn from the Saskatchewan River through intake pipes, and pumped by low-lift pumps to a sedimentation basin, in which the bulk of the solids are deposited. Hypochlorite of lime is applied to raw water before its entry into the basin. The water then flows by gravity to a battery of filters, thence to a clear water basin. By high-lift pumps the purified water is forced directly into the distributing mains, the normal pressure of 100 pounds being raised to 120 pounds, or thereabouts, for fire service.

The south side is supplied with water by an independent pumping station, without sedimentation or filtration. A submerged force main was partially laid during last winter. When the low stage of the river arrives this main will be completed and the south side will be supplied by filtered water from the main system. The mains and service pipes on the south side are now being filled with liquid mud that flushing cannot completely remove. Treatment by hypochlorite of lime is relied upon solely to reduce the bacteria.

Three intake pipes have been laid to date, not including the original intake of 1902, which was abandoned some years ago. One of these three is available during the winter months only; a second was blocked during the high water in 1912 and has not yet been cleared; the third, completed in 1913, is now furnishing the supply. This last is a 36-inch steel pipe provided with an intake crib located about 200 feet from the shore.

The low-lift machinery comprises three units, all steam-driven turbine pumps, and with a daily capacity of 12 million gallons. There is also an electrically operated turbine pump of three million gallons capacity which is used during winter months only. The high-lift machinery comprises two pumps of two and a half million gallons total capacity, steam-driven, now held in reserve in the original pumping station, a vertical Inglis plunger pump with a normal capacity of six million gallons, seldom operated, and two turbine pumps of the same capacity that are now relied upon for the normal supply. Two electrically operated turbine pumps, each with a capacity of 10 million gallons, are in the course of erection, and an additional low-lift, steam-driven unit of 18 million gallons capacity is on order.

In the original system an open sedimentation basin of less than one million gallons capacity was constructed, which gave satisfactory results. This basin is not now in use as part of the waterworks system. Another open basin has been constructed, with a capacity of about one and a half million gallons, into which the low-lift pumps discharge. By a central longitudinal baffle partition, the water entering at one corner is forced to flow from end to end, returning through the other half of the basin, the greater part of the silt being deposited near the inlet. This basin effects the removal of about 95 per cent. of the solids in suspension during the periods of maximum turbidity.

In 1910 the Roberts Filtration Company installed a temporary filtration plant comprising eight units, which, for various reasons, was not entirely satisfactory. In 1911 the company added four additional units of steel, the former units being of wood. Last season the results were more satisfactory, but not entirely so. This filtration plant is in the open, unhoused, and cannot be operated during the winter. In the autumn the filters are emptied, the filtering materials being replaced in the spring. The drying out of the wooden tubs caused them to leak and the cost of emptying and refilling them was no small item. This year the plant was overhauled, different sand used, and the results during July have been most satisfactory. The plant can now easily filter six million gallons daily, the effluent being perfectly clear, and the turbidity zero. Filtration alone materially reduces the bacteria present, but sufficient examinations and analyses have not as yet been made to warrant a statement being presented of the actual reduction made.

The city has under consideration an additional filtration plant of five million gallons daily capacity, comprising coagulating basins, filters, clear water reservoir, laboratory and chemical room, the entire plant to be enclosed in a suitable building.

The distribution system includes the following lengths of mains and sizes, laid to June 30th, 1913:

20-in.,	8,112 feet	14-in.,	5,923 feet	8-in.,	88,696 feet
18-in.,	2,889 feet	12-in.,	20,969 feet	6-in.,	343,419 feet
16-in.,	2,145 feet	10-in.,	40,517 feet	4-in.,	69,306 feet

This makes a total of 110.22 miles of pipe. Of the total distribution system over 70 per cent. is 6 in. and 4 in. in diameter, which is claimed to be too high a proportion for a waterworks system.

Necessity of Extension and Investigation of Supply.—The present unsatisfactory condition of the existing waterworks system in Edmonton is largely due to the unsettled question: Shall the supply continue to be drawn from the river at the present pumping station site, or shall the supply be taken from a source less liable to future pollution?

The demand for water is rapidly increasing, and additions to the present pumping plant are urgently needed. Further, improvements are required in the filtration plant and larger force mains are necessary to give proper fire protection.

Source of Supply.—There is no doubt that the city of Edmonton must rely upon the Saskatchewan River for its present and future water supply. The distance from the Rocky Mountains precludes mountain streams, and the elevations of the streams to the northwest, west and southwest of the city are insufficient to give a great supply. Pigeon Lake, distant about 42 miles southwest of the city, has been suggested as a source, but the conditions, when carefully studied, lead to the conclusion that it would not yield the requisite supply, neither would the quality of the water at all times be satisfactory, even after

*From a report dated August 9th, 1913, by Willis Chipman, C.E., to the City of Edmonton.

filtration. The capital cost of the project would be excessive. Further, it would only be a waste of time and money to investigate the possibility of securing a water supply from small streams and lakes or from deep wells. The city requires an unlimited supply of water, suitable for domestic and industrial purposes, delivered at a reasonable cost. This can only be supplied by the Saskatchewan River which flows through the city.

Quality.—Above the city the river water is free from sewage pollution, and there is no immediate prospect of cities or towns springing up upon the main stream or any of its tributaries between the city and the Rockies. The most serious objection to the river water is its turbidity, in which respect it resembles the Missouri at St. Louis, the Ohio at Cincinnati, and the Red River at Winnipeg.

During the months of May, June and July, 1911, the turbidity ranged from 5 to 850, and the solids in suspension from 167 to 2,260. During the same months in 1913, the turbidity ranged from 40 to 950, the average being 215.

The melting snow in the mountains during hot days or heavy rains produces great fluctuation in the river, from ten to twenty feet being the difference between low-water and high-water. In 1899 a level of 35 feet above low-water was attained, the highest observed since a traditional flood about sixty years ago.

High water is invariably accompanied by high turbidity, due to the caving in of cut banks. But during the late autumn and winter months, when the river is ice-bound, the water is clear, and for a month or more after the ice leaves the turbidity is low.

By the simple process of sedimentation, 95% of the solids may be removed, and the remaining 5% by filtration, the effluent being clear and sparkling. With a turbidity approaching 1,000 in July, 1913, the effluent from the filters was perfectly clear.

The hardness varies from 50 to 100 in the summer months, and the alkalinity from 100 to 200.

Recently bacteriological examinations of the river water have been made at the Provincial Laboratory, and show a high bacterial count. Sedimentation and filtration remove a large percentage of these bacteria, but treatment by hypochlorite of lime is relied upon to destroy those remaining.

The typhoid outbreak which occurred in September, 1912, was not attributed to the public water supply by the health authorities. The cause, however, has not been determined, and there is a likelihood that the water supply may have been contaminated, as the filtration plant was not working satisfactorily at all times. This season, however, the treatment of the supply is receiving more careful attention and the typhoid rate is below the normal.

Quantity.—The average quantity of water required for all purposes in cities of 100,000 population is about one hundred gallons per capita, where the services are unmetered. In metered cities the consumption varies from fifty to seventy-five gallons, the average being about sixty-six gallons; that is, by metering the capacity of the entire plant is increased by fifty per cent. As Edmonton is now an unmetered city, the consumption may be taken at one hundred gallons per capita.

At the present time about 40,000 people are supplied from the waterworks system, which is approximately sixty per cent. of the population. The maximum daily consumption frequently exceeds the average by fifty per cent., and the maximum rate of consumption may be double that of the average for the year.

The approximate quantities of water necessary for a city supply is presented below in tabular form, for different populations, where the supply is by the direct pumping:

Population	70,000	100,000	150,000	200,000
Gallons, daily average ...	4,000,000	6,000,000	9,000,000	12,000,000
Gallons, maximum average.	8,500,000	12,000,000	18,000,000	24,000,000
Fire streams required	21	25	31	35
Rate for fire supply	6,000,000	7,000,000	9,000,000	10,000,000
Total rate ...	14,000,000	10,000,000	27,000,000	34,000,000
Underwriters' requirements ..	14,000,000	17,500,000	24,500,000	30,000,000

River Pollution.—The Saskatchewan, like all rivers in an agricultural country, is polluted to a certain degree by surface drainage, and in the growing district surrounding Edmonton, this pollution will increase until the country is fully settled. This surface pollution cannot be prevented. Further, the April break-up of ice in the river, which has served as a highway during the winter months, produces a serious pollution for some weeks. This cannot be prevented, either. Both of these sources of pollution are more intense at the present waterworks intake than at points farther up the river, outside the city limits.

The greatest danger from pollution, however, is from storm water discharging directly into the river, conveying into it street washings, catch basin contents, etc. Likewise, domestic sewage may find its way into the river. Such dangers will increase annually. Disease germs therefrom cannot be entirely eliminated by sedimentation and filtration, although those remaining after such process may be destroyed by hypochlorite treatment. Not being in accord with the theory advanced recently that because it is possible to sterilize an impure water, it is therefore perfectly safe to adopt a cheap polluted water supply and trust to filtration and chemical treatment to insure safety, Mr. Chipman recommends that the future water supply for Edmonton be taken from the river at some point above the city limits. This conclusion is based upon a preference to secure the purest water obtainable, whereby less trust need be placed upon the efficiency of purifying apparatus, and chemicals, and the skill of employees.

New Works.—If new works be decided upon they will be of such magnitude that it may require three years for their completion after construction has commenced, while fully one year may be necessary in making surveys, in locating on and securing the land and right-of-way. Preliminary engineering work of this character is frequently so hurried that the best results are not obtained. It will also take time to provide transportation for building materials, plant, machinery, supplies, etc., and the fuel problem must also be satisfactorily solved before proceeding with construction.

To meet the demand for water during the period the new works are under construction, and until they are completed the existing pumping plant must be maintained and extended. The report deals fully with these extensions, a cost summary of which appears in a later paragraph.

Criticism of the Rabbit Hill Project.—Considerable space is given to the consideration of the Rabbit Hill scheme, as described in the previous report of a board of engineers. This hill is situated on Sec. 36, Twp. 52, R. 25, distant about six and one-fourth miles in a straight line from the Parliament Buildings and two and one-half miles east of the river. The elevation of the extreme top

of the hill is 152 feet above the general elevation of the city. This pinnacle, however, is limited in area, and slopes rapidly in every direction. The hill is of sand, and reservoirs and other works erected upon it would demand careful construction.

In this project it was proposed to locate the pumping station on the Prison Farm (Sec. 33) or in that vicinity, pump the raw water to Rabbit Hill, where sedimentation basins and filtration works were to be constructed, also a clear water reservoir, the clear water to flow by gravity to the city. In his criticism, Mr. Chipman refers to several weak points in this proposition. In the first place, turbid water should not be pumped through a long pipe line. The sedimentation basins and filtration plant should be located as near the pumping station as possible, and such works will occupy a considerable area of ground, when the city attains 200,000 population. The elevation of the ground at the Prison Farm does not furnish an ideal pumping site, the flats below the escarpment being below flood level. The pumping station might be constructed near the river at a point above flood level, the water pumped to basins on the plateau above, treated there and returned to the pump-house below.

From the pump-house the water would then be pumped to a clear water basin on Rabbit Hill, with not less than five millions of gallons capacity. The topography of the hill is such that it would be practically impossible to construct a reservoir of more than ten millions of gallons capacity. From the reservoir, the water would flow to the city by gravity. The static pressure on the north side of the city from the reservoir would be 130 feet or 56 pounds, but with ten million gallons flowing through one 36-inch main, the friction loss would be 16 pounds at the centre of the city. In the outlying sections the loss would be from 20 pounds upwards, depending upon the consumption and the size of the mains. With twenty millions discharging through one pipe, the friction loss would exceed the head from gravity. Three conduits would be then required—two for constant service, one for reserve—in order that 30 pounds to 40 pounds might be available for average domestic supply, as pointed out previously. The maximum rate may double the average and the fire supply must also be provided; that is, with a population of slightly over 100,000 the capacity of the conduits should approximate twenty million gallons.

The elevation of Rabbit Hill would not be sufficient to give a proper pressure or supply when the population exceeds 100,000, without additional conduits to the city, each of which would cost about half a million dollars. Better service can be given with much less expenditure by direct pumping, the pressure on the pumps being increased or decreased in proportion to the demands for water.

In the Rabbit Hill scheme, also, about two and one-half miles of conduits would be required between the pumping station and the river, the friction loss in which would increase the operating expenses. Assuming this system in operation, with three conduits leading from the reservoir, the pressure might be increased by one or more booster pumping stations located within the city, but this would be an expensive and complicated arrangement.

Criticism of the Beaver Hills Project.—The Beaver Hills are situated to the southeast of the city, distant approximately eight miles from the Parliament Buildings. These hills extend for some miles from northeast to southwest and on Section 16, Twp. 52, R. 23, the elevation of ponds near the summit of the enclosing ridges is about 200 feet above the city. A previous report suggested this location as a suitable reservoir site.

In this proposition raw water was to be pumped to large open reservoirs to be constructed among the hills, the natural ponds to be excavated, cleaned out and embanked where necessary. The first reservoir would act as a sedimentation basin from which the water would flow by gravity to filters thence to large open clear water reservoirs. Hundreds of millions of gallons of pure water stored at an elevation of 200 feet above the city appeals to the average citizen as an admirable waterworks scheme, eliminating for the present the matter of cost. There are, however, many points to be taken cognizance of that are not apparent to the layman. First, as stated under the Rabbit Hill scheme, turbid water cannot be pumped through long mains without causing trouble, sooner or later. Secondly, in open storage reservoirs, vegetable growths will cause offensive odors and tastes at certain seasons. Thirdly, the static pressure of 86 pounds would be reduced materially by friction loss, and the head required for filtration; and fourthly, the cost would exceed that of the Rabbit Hill scheme.

If this project were carried out, the raw water should be sedimented and filtered at the pumping station, then pumped to clear water reservoirs in the hills. The distance from a suitable pumping station site above the city to the proposed reservoir would not be less than eleven miles, and in addition conduits would be required leading from this conduit line or from the reservoirs to the city. The cost of the pumping station, filtration work, etc., would be practically the same as in the Rabbit Hill scheme, also the cost of the reservoirs, but the conduit lines would be about double the length and, therefore, double the cost.

Cost of Extensions to Existing System.—An estimate of the cost of the improvement proposed in the report is as follows:

First outlay at pumping station (new works necessary to guarantee a continuous service for a population of 100,000 people)	$ 330,000
Large distributing mains (also necessary for present requirements)	550,000
Second outlay at pumping station (additional works to provide for a population of 150,000)	460,000
Third outlay at pumping station (further additions to provide for 200,000 population)	390,000
Total	$1,730,000

Cost of New Works.—On the assumption that the city decide to locate a new pumping station at some point southwest of the city limits, the capital expenditure is estimated to be as follows:

Outlay at existing station (immediately required, as in alternate case)	$ 330,000
Large distributing mains (also required forthwith)	550,000
Outlay at new station, and one conduit pipe to city	980,000
Second outlay for 150,000 population	800,000
Third outlay for 200,000 population	250,000
Total	$2,910,000

The proposed new station, with its equipment, and the additions necessary to the present system, would

therefore exceed, by $1,180,000, the expenditure required if the present site be retained.

The following is a summary of the definite conclusions arrived at:

(1) That the existing pump house site in the central part of the city is an ideal one from an operative standpoint, as there is ample space for extensions to serve a population of half a million people or more.

(2) That the water supply at this point is not now seriously polluted, but the degree of pollution will undoubtedly increase with the population and may become positively dangerous when the population approaches 150,000.

(3) That a less contaminated supply may be obtained at some point above the city limits at a cost that cannot be considered as prohibitive.

(4) That the distribution system requires immediately many large feeder mains.

(5) That the Roberts filters now installed may be depended upon to filter six millions of gallons daily, the year round, if properly housed and additional clear water reservoirs and sedimentation basin be constructed this year.

(6) That the present station be enlarged to meet the city's demand for water until the new system is operative.

(7) That fire service by direct pressure be abandoned and portable fire engines adopted.

(8) That the waterworks department be consolidated and placed under one executive head.

(9) That about $880,000 should be appropriated for expenditures on the existing plant, including the feeder mains, whether the old pumping station site be retained or not.

(10) That neither the Beaver Hills project nor the Rabbit Hill scheme should be adopted.

THE HARRISBURG FILTER PATENT DECISION.

A COPY has just been received of the decision in the negative head patent case between the New York Continental Jewell Filtration Company, and the City of Harrisburg, Pa., as handed down a few weeks ago in the Middle District of Pennsylvania U.S. Circuit Court.

The case, which has been in the course of trial since the middle of 1908, has attracted wide attention, and the outcome is of extreme importance to the water filtration world, made so by the fact that the down-draft feature is now being used in most rapid sand gravity filtration plants.

Infringement of patents, commonly known as the negative head patents, was claimed by the Company on account of the building and use of the filter plant of the City of Harrisburg, which was erected in 1905, the engineer being Mr. James H. Fuertes, of New York City. It was claimed in this case that the Harrisburg plant was copied in design from the Little Falls plant of the East Jersey Water Company, which plant, according to the evidence, was designed by the complainant Company.

A few points which led up to the decision are as follows:—

The effective filtering agency in slow sand filters of the positive head gravity type is the sediment layer which gradually gathers on top of the sand in the form of an unbroken scum. This layer, a vital factor in filtration, is known as the "Schmutz-Decke." In more rapid, or mechanical, filtration plants, coagulants are used which rapidly form a film that corresponds in function to the "Schmutz-Decke."

As this surface sediment thickens it is so compacted by the head of water pressing upon it that there is little percolation, and further, its compact shell tends to create a vacuum beneath, which, by liberating the air in the passing water, also impedes percolation. In plants of the positive head gravity type of slow sand filtration this "Schmutz-Decke" is substantially the sole place where filtration occurs.

It is in this state of the art of filtration—with the slow formation of the surface sediment layer; with that layer constituting virtually the sole potent factor of filtration; with the sand bed being practically confined to forming the surface sediment shell; with vacuum regarded as a retarder of filtration, and tending to lessen plant output—that the involved patents entered. Mr. Ira Jewell in his process disclosed the radical suggestion that this vacuum, if of such relative completeness as to utilize its efficiency, could be made not only to avoid all troubles incident to air-releasing, but to utilize the whole sand bed as an active filtering agency. In other words, he claimed, by the proper use of vacuum, to convert virtually the whole sand bed into a "Schmutz-Decke."

The practical outcome of his process has been to create in sand filtration a differential type of plant known as the down-draft or negative head filter. It is bottomed on a vacuum, created by design, which results from an off-carrying pipe, vertically arranged and of such length that as the filtered water is carried off by it, a partial vacuum is created within the filter bed. The pipe extends downward a sufficient distance to provide the necessary down-draft, usually several feet. Its action is such that the entire body of filtering material is utilized instead of the upper surface only.

This mere insertion of a water-sealed vertical off-take pipe has added to filtration an important improvement, and the continued use thereof by the defending City of Harrisburg occasioned the charge laid by the Company.

From the evidence and discussion brought to bear upon the case, it was shown that the process really does, by the use of the down-draft sealed vertical outlet pipe, create and maintain an operative vacuum which effects a deeper utilization of the sand body for filtration than is found in positive head filters; that the presence of released air incident to the use of this vacuum is helpful and not harmful by reason of the velocity imparted to the passing water by such a vacuum; that the process makes the runs longer, and that both structural and maintenance costs are lessened by its use.

The court dwelt upon the question as to whether this disclosure involved invention. It was conceded to be an original conception. Further, it was not the mere suggestion of the use of the down-draft tube to create a vacuum. The originality and substance of the disclosure was pronounced to be in the utilization of the vacuum and the apparatus was the concrete means suggested to utilize the process. The disclosure was a marked departure from the previous ideas and practice; it gave to the whole of the large sand body a compacted functional working capacity that it did not previously have; it created a new type of filter in the art, and the process has gone into widespread and extensive use.

On these grounds the disclosure involved invention, according to the decision, and the claim of patent infringement was sustained.

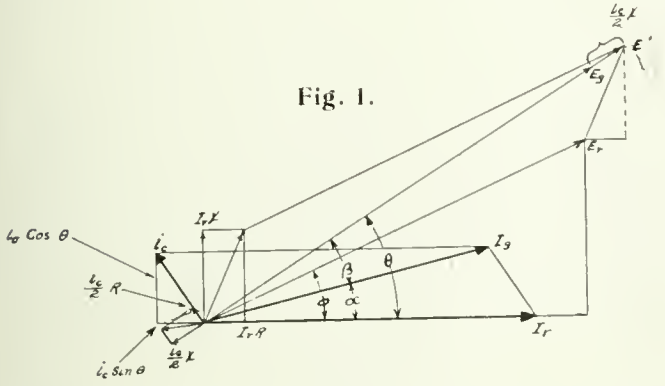
APPROXIMATE CALCULATIONS OF TRANSMISSION LINES WITH DISTRIBUTED CAPACITY.

By Bradley T. McCormick, M.E.

THE recent adoption of voltages of 110,000 and higher for power transmission, somewhat complicates the computations of transmission lines, due to the effect of capacity which can no longer be neglected at such high voltages. During recent years several articles have been published, giving the exact mathematical treatment of transmission lines with distributed capacity, but these usually involve the use of hyperbolic functions, and the formulas are too complex to be of any practical value.

Dr. Steinmetz, in his discussion of Percy H. Thomas' paper on "Output and Regulation of Long Distance Transmission Lines," (A.I.E.E., 1909, Volume 1, page 712), gives the exact formulas on transmission lines with distributed capacity, in a very much simplified form; while in the June issue of the General Electrical Review is an article by Mr. F. W. Peek, Jr., in which the exact formulas of Steinmetz are still further simplified. However, in using Peek's method it is necessary to perform several multiplications of complex variables. Anyone who does not use complex variables frequently is liable to be out of practice and make mistakes in signs.

Fig. 1.



Mr. Peek, in his article, works out some examples on a 120,000-volt transmission line 130 miles long, and in his calculations he adds the resistance and reactance of the step-up and stepdown transformers to the resistance and reactance of the line. Since in the transmission line the resistance and reactance are distributed while in the transformers they are concentrated, the formulas, when used in this manner, are therefore not exact, after all. It is also worthy of note that the charging current does not flow through the impedance of the step-down transformers, as assumed by Mr. Peek. In view of the above, there is nothing gained by the use of the exact formulas, if approximate formulas can be found that will give fairly close results. Approximate formulas based on the assumption that the capacity of the transmission line is concentrated at the centre will give results agreeing very closely with Peek's, more exact formulas, though it may sometimes be necessary to calculate some of the values twice, the first calculation being approximate, and the second more accurate.

Below are given some formulas which the writer has found to agree very closely with the exact formulas. Several calculations have been made on Mr. Peek's transmission line so that the values obtained can be compared with those obtained in his article.

Symbols.

Let E_r = receiver voltage between lines,
Let E_g = generator voltage between lines,
Let I_r = current at receiver end of line,
Let I_g = current at generator end of line,
Let i_c = charging current at generator end of line,
x and R = three phase reactance and resistance = $\sqrt{3}$ times the value per log,
Let ϕ = power factor angle of receiver circuit,
Let β = power factor angle at generator,
Let θ = angle between generator voltage, E_g, and receiver current I_r,
Let α = angle between generator current, I_g, and receiver current I_r,
Let c = capacity of line to neutral,
Let l = distance in miles that power is transmitted,
Let d = distance apart of wires, centre to centre in inches,
Let r = radius of wire, in inches,
Let cm = area of conductor in circular miles,
Let $\sim$ = frequency in cycles per second.

Formulas.

(1.) $R = 56{,}000 \frac{l}{\text{cm}}$ for copper and $89{,}000 \frac{l}{\text{cm}}$ for 63% conductivity aluminium.

(2.) $X = \sqrt{3}\, 2\pi \sim l\, (.00074 \log_{10} \frac{d}{r} + .00008)$.

(3.) $C = \frac{.0194}{\log_{10} \frac{d}{r}} l$.

(4.) $i_c = \frac{2\pi \sim C}{\sqrt{3}\, 10^6} \times \frac{E_g + E_r}{2}$.

(5.) $E_g^1 = \sqrt{(E_r \cos\phi + I_r R)^2 + (E_r \sin\phi + I_r x)^2}$.

(6.) $E_g = \sqrt{(E_r \cos\phi + I_r R)^2 + (E_r \sin\phi + I_r x)^2} - \frac{i_c}{2} x$

$= E_g^1 - \frac{i_c}{2} x$.

(7.) $\sin\theta = \frac{E_r \sin\phi + I_r x}{E_g^1}$.

(8.) $\cos\theta = \frac{E_r \cos\phi + I_r R}{E_g^1}$.

(9.) $I_g = \sqrt{(I_r - i_c \sin\theta)^2 + (i_c \cos\theta)^2}$.

(10.) $\sin\alpha = \frac{i_c \cos\theta}{I_g}$.

(11.) $\beta = \theta - \alpha$

(12a.) Loss in line $= [I_r^2 + I_r (I_g - I_r) + \frac{1}{3} (I_g - I_r)^2] \sqrt{3} R$, when I_g is greater than I_r;

(12b.) or $[I_g^2 + I_g (I_r - I_g) + \frac{1}{3} (I_r - I_g)^2] \sqrt{3} R$ when I_g is less than I_r.

Line Constants of Mr. Peek's Line.

$R = \sqrt{3} \times 39.5 = 68.2$ ohms.
$X = \sqrt{3} \times 182.4 = 316.$ ohms.
$\cos\phi = .85$, $\sin\phi = .53$.
$E_r = 120{,}000$ volts.
$C = 1.735$ M.F.

Check on 5,500 kw. Load at Receiver at 85% Power Factor, $I_r = 31.1$ Amperes.

From (5) $E_g^1 = \sqrt{(120000 \times .85 + 31.1 \times 68.2)^2 + (120000 \times .53 + 31.1 \times 316)^2}$, $= \sqrt{104125^2 + 73300^2} = 127000$ volts.

As a first approximation assume $E_g = E_r$, and from (4)

$i_c = \frac{2\pi 60 \times 1.735}{\sqrt{3}\, 10^6} \times 120000 = 45.3$ amperes,

From (6) $E_g = 127000 - \frac{45.3}{2} 316 = 127000 - 7150 = 119{,}850$ volts,

The voltage at the generator is, therefore, approximately the same as at the receiver when operating at 55,000 kw. load at 85% power factor. Our assumption that $E_g = E_r$ is therefore very close and it will be unnecessary to recalculate the charging current i_c.

From (7) and (8) $.577 \text{ Cos } \theta = \frac{104125}{127000} = .82$ $\theta = 35°$ Sin $\theta = \frac{73300}{127000}$.

From (9) $I_g = \sqrt{(31.1 - 45.3 \times .577)^2 + (45.3 \times .82)^2} = \sqrt{4.9^2 + 37.1^2} = 37.5$ amperes.

From (10) Sin $\alpha = \frac{45.3 \times .82}{37.5} = .99$, $\alpha = 82°$.

From (11) $\beta = \theta - \alpha = 35° - 82° = -47°$, Cos $\beta = .682$.

The minus sign denotes a negative angle of lag or an angle of load, indicating that with a load of 5,500 kw. at 85% power factor lagging at the receiver end, the charging current is sufficient to give a leading current of 68.2% power factor at the generator.

From (12) Loss in line $= [31.1^2 + 31.1 (37.5 - 31.1) + \frac{1}{3}(37.5 - 31.1)^2] \sqrt{3}\ 68.2 = 138.5$ KW.

Check on 44,000 kw. Load at Receiver at 85% Power Factor. $I_r = 249$ Amperes.

From (5) $E_g^1 = \sqrt{(120{,}000 \times .85 + 249 \times 68.2)^2 + (120{,}000 \times .53 + 249 \times 316)^2} = \sqrt{(119{,}000)^2 + (142{,}300)^2} = 185{,}500$ volts.

As a first approximation assume that $E_g = E_r$ and as before, see (4) then, $I_c = \frac{2\pi \times 60 \times 1.735}{\sqrt{3} \times 10^6} \times 120000 = 45.3$ amperes.

From (6) $E_g = 185{,}500 - \frac{45.3}{2} 316 = 185{,}500 - 7{,}150 = 178{,}350$ volts.

Our assumption that $E_g = E_r$ is therefore incorrect, so we must recalculate i_c from (4) and substitute again in (6) to get E_g.

$$i_c = \frac{2\pi \times 60 \times 1.735}{\sqrt{3} \times 10^6} \quad \frac{178{,}350 + 120{,}000}{2} = 56.2$$

amperes.

Substituting again in (6) $E_g = 185{,}500 - \frac{56.2}{2} 316 = 185{,}500 - 8{,}900 = 176{,}600$.

This compares very closely with $E_g = 177{,}300$ as obtained by Peek from his more accurate formulas.

From (7) and (8) Sin $\theta = \frac{142{,}300}{185{,}500} = .766$ Cos $\theta = \frac{119{,}000}{185{,}500} = .641$ $\theta = 50°$.

From (9) $I_g = \sqrt{(249 - 56.2 \times .766)^2 + (56.2 \times .641)^2} = \sqrt{208.7^2 + 36.1^2} = 212$ amperes.

From (10) Sin $\alpha = \frac{56.2 \times .641}{212} = .17$ $\alpha = 9.78°$.

From (11) $\beta = \theta - \alpha = 50 - 9.78 = 40.22°$ Cos $\beta = 7.65 =$ power factor at generator.

The plus sign for β indicates a lagging current at the generator.

From (12) Loss in line $= [212^2 + 212 (249 - 212) + \frac{1}{3}(249 - 212)^2] \sqrt{3}\ 682 = 6{,}300$ KW.

Check on no Load.

Assume as a first approximation that the voltage at the generator and receiver ends of the line are equal. As a first approximation we have as charging current from (4)

$$i_c = \frac{2\pi 60 \times 1{,}735}{\sqrt{3} \times 10^6} 120{,}000 = 45.4.$$

Since there is no load on the receiver, $I_r = 0$ and (6) becomes,

$$E_g = E_r - \frac{i_c}{2} x = 120{,}000 - \frac{45.4}{2} \times 316 = 120{,}000 - 7{,}180 = 112{,}820 \text{ volts.}$$

Now recalculates i_c from (4),

$$i_c = \frac{2\pi 60 \times 1{,}735}{\sqrt{3} \times 10^6} \times \frac{112{,}820 + 120{,}000}{2} = 44.1 \text{ amperes.}$$

Recalculating the generator voltage from (6),

$$E_g = 120{,}000 - \frac{4.41}{2.} 316 = 120{,}000 - 7{,}000 = 113{,}000.$$

$$\text{Line loss} = \frac{1}{3}(44.1^2 \sqrt{3}\ 68.2) = 76.5 \text{ KW.}$$

The following table gives the comparison of the results obtained by Mr. Peek's formulas and the approximate formulas as worked out on the transmission line treated above. It will be noted that the difference between the results obtained by the two methods is in most cases very small, and in other cases close enough for practical purposes.

Derivation of the Transmission Formulas.

Formulas (1), (2) and (3) are the usual ones employed for transmission lines, and need no explanation. The capacity is treated as if a condenser were concentrated in the centre of the line, so that the charging current flows through only half of the impedance of the line. It is considered that the voltage across the condenser is equal to the average of the voltage at the generator and receiver ends of the line or $\frac{E_g + E_r}{2}$. The charging current is, therefore, expressed as in formula (4). It is assumed that the phase position of the charging current is 90° ahead of the generator voltage E_g. This is not strictly correct, since for that portion of the line nearest the generator the charging current is 90° ahead of E_g, while for that portion nearest the receiver the charging current is 90° ahead of E_r. The voltages E_g and E_r are not in phase but differ by the angle $\phi - \theta$.

If there were no capacity in the transmission line the voltage at the generator end would be expressed in the usual way by formula (5). However, if capacity cannot be neglected there must be added to E_g the voltage consumed by the charging current flowing through the impedance of the line. This voltage may be split into two components $-\frac{i_c}{2} x$ in phase with E_g^1 and the component $-\frac{i_c}{2} R$ in quadrature with E_g^1. We should therefore write

$$E_g = \left\{ [\sqrt{(E_r \cos + I_r R)^2 + (E_r \sin + I_r x)^2} - \frac{i_c}{2.} x]^2 + [-\frac{i_c}{2} R]^2 \right\} ½$$

The second term $-\frac{i_c}{2} R$ can be neglected so that the equation will take the form shown in formula (6). Neglecting this last term bring E_g and E_g' in phase, as shown in the figure. This is not strictly correct, but the error resulting from this assumption is small. The sine and

cosine of the angle between the receiver current and the generator voltage can be expressed by formulas (7) and (8).

The current at the generator is the vectorial sum of the receiver current and the charging current. The charging current may be split into two components $i_c \sin \theta$ in phase with I_r, and $i_c \cos \theta$ in quadrature with I_r. We may, therefore, express the generator current by formula (9).

For the purpose of calculating the energy loss of the line, we will assume that the difference between the current at the receiver and generator ends follows a straight line law. This is not strictly true, but is close enough for present purposes. In Fig. 2 it is assumed that the receiver current is greater than the current at the generator. The current I at any point distant l from the generator end will be $I = I_g + a$ where a is a constant.

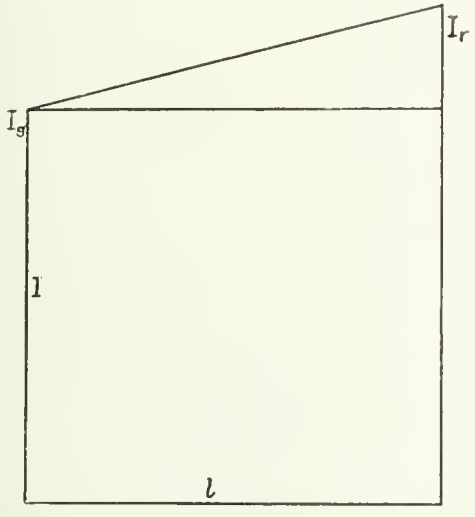

Fig. 2.

The mean square value of current can be obtained as follows:—

$$\frac{1}{l}\int_0^l I_g^2\,dl = \frac{1}{l}\int_0^l (I_g^2 + 2I_g a l + a^2 l^2)\,dl$$

$$= \frac{I_g^2 l + I_g a l^2 + \frac{1}{3} a^2 l^3}{l}$$

$$= I_g^2 + I_g a l + \frac{1}{3} a^2 l^2$$

But $a = I_r - I_g$ so we have

$$I_g^2 + I_g (I_r - I_g) + \frac{1}{3} (I_r - I_g)^2$$

This is the mean square value of the current and when multiplied by $R\sqrt{3}$ is the line loss as in formula 12b. If the current at the generator end is larger than that at the receiver end of the line the expression for energy loss takes the form given in formula 12a.

Twenty-four railway lines radiate from Winnipeg. The Canadian Pacific Railway, Canadian Northern Railway and Grand Trunk Pacific shops are all located there, employing over 5,000 hands; with 130 miles switch siding facilities for manufacturers. Water transportation on Red and Assiniboine Rivers; vessels drawing nine feet of water ply between Winnipeg and Lake Winnipeg, a body of fresh water, in area, 9,414 square miles. The Winnipeg electric railway carried three million people in 1900 and 35 million in 1912, operating over 300 cars on over 72 miles of city tracks and 45 miles of suburban lines.

BELT CONVEYERS.

By Reginald Trautschold, M.E.

OBVIOUSLY, the easiest way—so far as consumption of power is concerned—of transporting material from one place to another is to carry or convey it on a moving body rather than to attempt to drag it along a trough, as in the case of flight conveyers; or to push it, as in the case of screw conveyers. Obviously, also, the simplest kind of conveyer carrying its load on moving parts consists of an endless belt running over end pulleys and supported throughout its length by occasional supporting idlers, or carriers, on the carrying stretch of the belt and by less frequent supporting idlers on the return or lower run of belt. Such apparatus, belt conveyers, have now been brought to such a high state of perfection that they are almost indispensible in the handling of materials in bulk and are also used to great extent in carrying packages, boxes, bales, etc. This latter application of belt conveyers usually requires a flat carrying surface (belt) running between guides to prevent the load from leaving the belt. Material in bulk, such as ores, coal, cement, paper pulp, wood chips, etc., etc., on the other hand, are most frequently carried on troughed belts, belts having their edges turned up and inclined to the plane of the conveyer so as to form a trough in which the material is carried, thus materially increasing the carrying capacity. Troughed belt conveyers being more generally and widely used, they will be chiefly considered in this discussion.

The original troughing idler, or belt carrier, consisted of a spool-shaped pulley or series of individual pulleys mounted so as to form a spool. Following this form came the "dish pan" idler, consisting of one or more centre pulleys of the same diameter between concentrating end pulleys of "dish pan" shape which turned up the edges of the carrying belt. These simple types of carrying idlers had the desired effect of troughing the belt, but they possess one very undesirable feature, the circumferential speed of the pulley or pulleys varying with their diameter while the speed of the belt passing over them is constant from edge to edge; the result being that either the belt was travelling faster than the circumference of a particular pulley, or else the belt lagged behind certain circumferential of the troughing idler, causing much unnecessary wear on the belt due to the scouring action between the contact surfaces of belt and troughing idler. Relatively, the belt is the most expensive part of a belt conveyer and the main improvements have necessarily been in the troughing idler to obviate slippage between it and the belt. Troughing idlers are now almost invariably constructed of several individual pulleys of the same diameter mounted so that the end pulleys are inclined to the horizontal and cause the carrying belt to form a trough conforming more or less to an arc of a circle. These individual pulleys constituting a troughing idler may be mounted all in one plane, the end pulleys in a plane in advance or behind that of the centre pulley, may be mounted on hollow shafts in which grease for lubrication is stored and which is supplied to the bearings through small holes in the hollow shafts, mounted on solid shafts with either grease or oil lubrication, or on ball bearings that require only occasional lubrication, depending upon the construction and patent rights of the manufacturer. The latest construction consists of complete individual units of one pulley each which may be mounted on a board so that the pulleys all lie in one plane and may be

so inclined as to form any desired form of trough. Any of these various types of troughing idlers will give satisfactory results if properly proportioned and, which is even of greater importance, if properly cared for. Particularly, must care be taken not to allow the lubricant to come in contact with the belt, oil or grease having a harmful action on rubber—the material that enters the construction of most belts.

The angle with the horizontal made by the inclined pulleys of the troughing idler varies considerably, being but 10 to 20 degrees in some cases and in others as much as 35 or 40 degrees. Deep troughed conveyers, those in which idlers with steeply inclined end pulleys are employed, have slightly greater carrying capacity than conveyers with more shallow trough, it is true, but such gain is counteracted somewhat by increased power requirements and by increased wear on the belt by the material handled. One of the most successful manufacturers of belt conveyers builds all troughing idlers with end pulleys inclined at about 25 degrees (slightly less in most cases). This angularity would seem to be about the most satisfactory, for with such it is possible to attain within 10 or 15 per cent. of the theoretical capacity of the conveyer, while even with the deepest practical trough the theoretical capacity cannot actually be reached and both depreciation, through abrasive wear of material slipping on the belt, and power requirements are unduly enhanced. A deeper trough may be advisable at loading points, however, as such construction would have the tendency to facilitate the proper arrangement of load on the belt for subsequent conveying. Theoretically, the capacity of a belt conveyer is limited by the amount of material that can be piled on a flat belt of the same width and is, therefore, dependent upon the angle of repose of the material handled. This arbitrary limitation is due to the fact that at some section of every belt conveyer the belt must be flattened. This may be either over the flat pulleys constituting discharging devices, or over the flat bend pulleys where the direction of the conveyer makes a sudden change, or, for conveyers in which there is no interruption to the trough from loading point to point of discharge, over the head pulley of the conveyer. A well proportioned belt conveyer carrying suitable material—i.e., material that is not too bulky for the size of conveyer, that possesses no disadvantages of undue heat or other quality productive of disastrous chemical action on the belt, etc.—has a pretty rigidly fixed carrying capacity at a given speed, however, and Table V. contains such data for conveyers handling material weighing 100 pounds per cubic foot at a conveyer (belt) speed of 100 feet per minute. Conveyers carrying material of other weight have capacities proportionally greater or less according to the weight of the material and, of course, the capacity of any belt conveyer varies directly with the speed at which it is run. Similar data, expressed in the form of a convenient equation, is given as Formula XIII.

Capacity :—

$$W = \frac{1.43\ w^2 V W'}{100{,}000} \qquad \text{Formula XIII.}$$

Where W = Weight of load (capacity) conveyed in tons per hour.
w = Width of conveyer (belt) in inches.
V = Velocity (speed) of conveyer in feet per minute.
W′ = Weight of material handled in pounds per cubic foot.

Table V.—Capacity of Belt Conveyers, Continuously and Uniformly Loaded.

Material weighing 100 pounds per cubic foot.
Conveyer speed, 100 feet per minute.

Width of belt.	Tons per hour.	Width of belt.	Tons per hour.
12″	20.0	26″	96.0
14″	27.0	28″	108.6
16″	35.7	30″	126.8
18″	45.0	32″	143.5
20″	55.6	34″	160.0
22″	67.7	36″	183.0
24″	80.0		

All materials suitable for handling by belt conveyers are not necessarily possible of conveyance at the same speed, however, and this question of advisable speed is one over which there has been considerable controversy

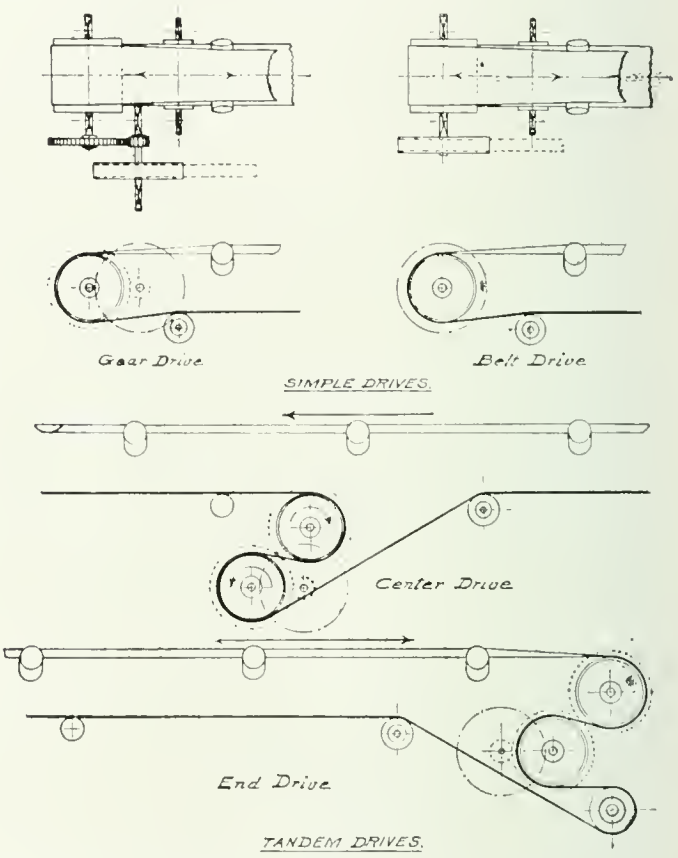

Fig. 1.—Diagrams of Typical Belt Conveyer Drives.

and no fixed rule can be advanced to cover all cases. Ordinarily, heavy materials can be carried at a higher speed than lighter ones, but practice has brought out many exceptions to such a rule. Table VI., compiled from records of a number of successful and efficient installations of belt conveyers, gives suitable speeds for handling a variety of the commoner materials usually conveyed by this class of apparatus, together with the average weight of such materials. The speeds given in the table allow for considerable lee-way, for a variation of as much as 20 to 30 per cent. is allowable and frequently advisable.

Before taking up a consideration of the power requirements and economic value of the belt conveyer, it is advisable to study in some detail the construction of the apparatus, general design of systems, etc. The troughing idlers that have already been considered are usually

spaced from 3 to 6 feet apart, depending upon the width of the belt and to some extent upon the character of the material handled. The return idlers, those carrying the lower run of belt, are invariably of pulleys in the same horizontal plane; that is, a return idler has all its individual pulleys in the same plane; and are spaced about twice as far apart as the troughing idlers. Guide idlers, in a plane tangent to the edges of the conveyer belt, are required for long conveyers to prevent the belt from leaving the troughing idlers and these are usually spaced 40 or 50 feet apart. The driving pulley of the conveyer may be one of the end conveyer pulleys driven through suitable gear-reducing mechanism or simply by a driving pulley fast to the shaft of the conveyer driving pulley if the speed of rotation can be satisfactorily controlled without gears. In installations where such simple drive is not feasible, a centre drive may be installed, consisting of tandem conveyer driving pulleys around which the return run of the conveyer belt passes in the form of an "S." This type

Table VI.—Economic Speeds of Belt Conveyers for Various Materials.

Material.	Weight per cubic foot.	Advisable speed.
Coke	32 to 35 lbs.	250 ft. per min.
Broken stone (coarse)	160 to 170 lbs.	250 to 300 feet
Lump coal, R/M	50 to 60 lbs.	250 to 300 feet
Ashes	About 45 lbs.	300 ft. per min.
Lime and cement	50 to 80 lbs.	300 ft. per min.
Ore	About 125 lbs.	300 to 400 feet
Crushed stone	150 to 170 lbs.	350 to 400 feet
Sand and gravel	100 to 120 lbs.	350 to 400 feet
Fine coal	About 50 lbs.	400 ft. per min.

of drive is also employed at the ends of the conveyer when a conveyer is particularly long or when the service is so severe that the simple end conveyer pulleys do not have sufficient belt grip to drive the conveyer. Excessively severe conditions of drive are also met by covering the conveyer driving pulley or pulleys with a "lagging"—material that increases the grip of the pulley on the belt. Means must also be provided for adjusting the tension in the conveyer belt, and this is usually accomplished by providing take-up bearings for the conveyer pulley at the opposite end of the conveyer from the driving end, though the take-up may be located at any convenient point on the return run of the belt. The driving pulleys should be of the heavy crown type and should be slightly greater in diameter than the width of the conveyer belt; their face should also be about two inches greater than the width of the conveyer belt. The end conveyer pulleys, if not used as conveyer driving pulleys, may be somewhat smaller in diameter and the upper and lower runs of conveyer belt should be about parallel except at the point where the driving conveyer pulley is installed—the greater diameter of such pulley increasing its grip on the belt.

Not only is the belt the most important part of a belt conveyer, as upon it the load is carried, but it is also relatively the most costly. All the abrasive wear caused by material slipping on the belt at time of loading and during a certain unavoidable slippage while in transit is naturally concentrated on the belt itself and the depreciation from such causes constitutes by far the greatest expense of maintenance. Belts of many materials have been experimented with and that found the most generally satisfactory is the rubber belt, a belt that is composed of the necessary plies of heavy duck for strength bound together with a rubber "friction" and protected by a rubber covering that is considerably thicker on the carrying side (top of belt on the upper run). Such a belt is comparatively expensive—a conveyer so equipped costing nearly twice as much as one in which the conveyer belt is of stitched canvas construction without rubber covering—but is by far the most economical and satisfactory in the majority of installations, owing to its excellent properties of resisting abrasive wear. The rubber covering of a conveyer belt should not be highly vulcanized, but should be quite resilient, as the tendency of the material to slip on the hard belt is much greater than when the adhesion of the particles of material in contact with the belt is more tenaceous—the case with the relatively soft resilient belt. Refinements of the standard rubber belt of uniform thickness, with the same thickness of rubber wearing cover from side to side of belt, have been made in attempts to lengthen its life for conveying purposes and, for installations presenting exceptionally trying conditions of service, two of these patented types deserve particular consideration and criticism. One of these belts has sections of the duck plies omitted on its carrying side, the gaps increasing in width as the plies approach the surface of the belt, and replaced with rubber, making a belt with a rubber cover that is thickest at the centre of the belt and becomes thinner towards the edges. This construction, augmented by stiff reinforcement of the edges, makes a very pliable belt that readily conforms to the trough of the conveyer. Another claim that is advanced by the manufacturers of this belt is that it possesses greater wearing qualities, owing to the fact that the rubber cover is thickest at the centre where the wear is claimed to be the greatest. In installations of conveyers in which the load is carried up so steep an incline as to cause a slippage of material (load) on the belt or where the belt is run at such speed that a vibratory oscillation of the belt as it passes over the troughing idlers is great enough to cause readjustment of load on the belt. This claim is substantiated, and even in installations where neither the inclination of the conveyer nor the speed at which it is run is excessive the agitation of load in passing over the troughing idlers may be sufficient to create a slight and continual readjustment of load, causing a certain scouring action on the surface of the belt. In such cases, the wear is naturally greatest at the centre of the belt where the load is the thickest and consequently the heaviest. Whenever the carrying belt passes over a flat pulley, however, rearrangement of load on the belt is necessary and the portion of load that changes position is not at the centre, but toward the edges of the belt. Another change of location or position of load on the belt takes place on retroughing the flattened belt and, as in the case when flattening the belt, the abrasive wear takes place along the edges of the loaded section of belt. In a properly installed system, in which the tension on the conveyer belt is maintained correctly, the main wear of the load, other than that which may be caused at the loading point when charging the conveyer, *is* toward the two edges of the belt. However, as the section of the conveyer belt covered by the load never extends to the edges of the belt, the abrasive wear due to the shifting of load on passing over a flat pulley comes at a point on this patented belt where the rubber is still comparatively thick, so that this construction produces an excellent belt. The second noteworthy special rubber conveying belt is one that has some of the plies of duck omitted at the point where the belt would turn upward if it followed closely the pulley surfaces of a three-pulley troughing idler and the gap thus formed filled with rubber, which construction also makes

a pliable belt that clings to the troughing idler pulleys. This belt has no extra cover at its centre, so possesses no particular wear-resisting qualities where the load is the thickest, but does possess increased resisting properties against abrasive wear at the hinged points just outside the limits of the centre pulley. The peculiar shape to the trough when using the "hinged belt" also increases the carrying capacity of the belt to some extent, but the readjustment of load on passing over a flat pulley is correspondingly greater and necessarily the abrasive action of the load in shifting its position on the belt is augmented. Both these patented belts are of necessity more expensive than belts in which the refinements of varying the thickness of rubber cover are not attempted—straight ply belts —and, without disparagement of the patented belts, it is a question whether greater benefit might not be gained by putting the extra money into a straight ply belt with an extra heavy rubber cover of uniform thickness.

Take-Up
Horizontal Conveyor.
Maximum inclination about 21° or 22°
Plain Inclined Conveyor
Combination Plain Inclined & Horizontal Conveyor
Combination Curved Inclined & Horizontal Conveyor.
Horizontal Conveyor with a series of Fixed Dumps.
Horizontal Conveyor with Traveling Tripper.

Fig. 2.—Typical Arrangements of Belt Conveyers.

NOTE.—Installations of Belt Conveyers may consist of any combination of the above arrangements and conveyers can frequently be made reversible—i.e., arranged so they be operated in either direction. They also may be loaded at more than one point, can be driven at any point and the Take-Up can be loaded wherever convenient.

Fixed Dumps may be installed on any horizontal stretch of conveyer or inclined stretches may be interrupted for their accommodation.

Traveling Trippers may be installed on any horizontal or slightly inclined stretches of conveyer, may be propelled by hand or be of the automatically traveling and reversing type.

Provision for discharging the load from belt conveyers, other than over the end pulley of the conveyer, necessitates the forming of an "S" in the carrying belt, similar to that required in the return belt for a tandem drive, the load leaving the conveyer as the belt passes over the upper of the two straight pulleys employed to so guide the belt. This discharging arrangement may be mounted on a movable carriage that can be moved from position to position by a hand crank (hand-propelled tripper) or else the motion of the moving conveyer belt may be employed automatically to cause the tripper to travel back and forth over a fixed length of track on which the tripper is supported (automatic tripper). When it is required to discharge load at only a specified point or at several fixed points in the length of the conveyer, the discharging device is usually made permanent, part of the supporting structure of the conveyer system, and is known as a "fixed dump." By arrangements of chutes and gates, either trippers or fixed dumps may be made to discharge the conveyed load on either side of the conveyer in any desired proportion, and may also be arranged to discharge any proportion of the load to the conveyer belt beyond the particular discharging point for subsequent discharge at some further advanced point.

Belt conveyers carrying wet or sticky materials also require brushes for cleaning the belt at each discharge point. These brushes are usually of the rotary type, constructed of stiff bristles, and are gear- or belt-driven from the conveyer pulley over which discharge of load takes place—rotation of brush being in the opposite direction to that of the conveyer pulley.

(To be continued.)

COAST TO COAST.

Ottawa, Ont.—"Until the report of Sir Alexander Binnie, founded on his own investigation and those of his engineers, is submitted, I do not propose to give out any information whatever, and anything which may be published in the meantime must be regarded as only conjecture." This was the statement made by Mayor Ellis recently in regard to the water scheme. "I expect to have complete reports upon every phase of the water question ready to submit to council in October," added Mayor Ellis.

Ottawa, Ont.—The appointment of a commission to consider the practicability of the Georgian Bay Canal project will be taken up shortly by the Minister of Public Works. Heretofore the investigations have had reference wholly to the engineering features of the work and the estimate of its cost. What is now proposed is an inquiry into the economic aspect of the project and its probabilities as a profitable proposition.

Windsor, Ont.—Seeking protection from disease or possible contamination of the city's water supply, the members of the Windsor Water Board and Medical Health Officer Ashbaugh have gathered several samples of Detroit River water near the mouth of the intake pipe and in the current flowing directly into the pipes. The samples will be packed and shipped at once to the Ontario Health Board at Toronto for analysis. The water was obtained from near the bottom of the river by means of an especially devised apparatus, consisting of a metal box containing a sterilized bottle. The equipment was lowered to the required depth and the bottle uncorked. While Windsor's water supply is taken from the channel in the river and not from the lake, former tests have shown it to be as pure as any water in the Dominion. Only two samples out of nearly a dozen taken last summer were found to contain the least trace of contamination.

St. John, N.B.—Mr. H. A. Powell, K.C., member of the International Waterways Commission, has left for Grand Falls and vicinity to conduct an investigation into the boundary waters, which, it is understood, have given rise to much serious consideration through their pollution. The idea of the visit of Mr. Powell, who is acting in the interests of both the United States and Dominion Governments, is to investigate the waters with the intention of reporting as to the extent of the pollution, the interest of each country in the matter, and the remedial measures which are deemed necessary with a view to the protection of the health of the dwellers

in the vicinity. The Board of Health officials will be conferred with and a thorough examination of the waters from a bacteriological standpoint will be undertaken. After the scientific examination has been completed, Mr. Powell will report as to the nature and extent of the contamination and the precautionary measures necessary to protect the residents. The responsibility which rests upon each country in connection with the waters under examination will also be considered. The problem of investigating and inquiring into the condition of waters in different countries believed to be contaminated is now occupying the serious attention of every country where the danger is found, and it is most necessary that remedial measures be considered at the inception of the pollution. In such a connection a commission has for the past ten years been conducting scientific examinations on the waters of the Thames River in England.

Toronto, Ont.—Mr. E. A. James, Highways Engineer, is back in his office again after a tour of inspection of the work being done by the Commission in York County. At Unionville the abutments for the new bridge are finished, and the bridge at Markham Village has been started. In the western part of the county a new concrete bridge is under way at Kleinburg, and a 40-foot concrete retaining wall near Woodbridge to protect the roadway from the spring freshets of the Humber River is being built. The repair gangs are all out and busy at their work of keeping the good roads in proper shape. Spoken to regarding the road on Yonge Street, Mr. James explained that within the city limits, near Hogg's Hollow, it is badly rutted in places. Near the foot of the hill the oil put on by the Commission had not penetrated the earth, but had formed a crust on top. This was now breaking up, but the repair gang would soon have that in first-class shape. "If they are prepared to give us the money," said Mr. James, "we can easily lay asphalt roads in York County. But they would cost $25,000 per mile as against the $5,000 the Yonge Street roadway has cost. There is also the cost of repairing an asphalt roadway to be taken into account, and this would prove almost prohibitive in the county. The plant required is too cumbersome to be easily moved long distances over the county roads, and it would pay to move it only to districts where extensive repairs were necessary. Then a well-built macadam roadway is better fitted to carry the class of traffic that uses the country roads. Commissioner Harris compelled the owners to remove the cleats from the wheels of motor trucks in Toronto, because of the damage they did to the asphalt. What a heavy traction engine, with its cleated wheels, drawing a tank, would do to a country road built of asphalt can be better imagined than described."

Toronto, Ont.—One of the things which it is understood the Ontario Government may lay hold upon when the Legislature convenes early in the new year, is the problem of water purification and sewage disposal. The numerous instances of difficulty which municipalities have encountered during the past year and the general desire for reliable methods of solution were instrumental in the sending of Dr. J. W. S. McCullough, chairman of the Provincial Board of Health, to the Continent this summer to gather information on the subject in general. He returned recently from a nine weeks' tour of investigation and will present an authoritative report within a short time to the Cabinet. In the same manner a report will be made up for the consideration of the Federal House by Dr. C. A. Hodgetts, chairman of the Commission on Conservation, who travelled in company with the Ontario representatives. Dr. McCullough, in company with Dr. Hodgetts, made an especially exhaustive study of sewage and water conditions in Great Britain, and brought home voluminous notes on the different systems in use in the different cities. The aim in every case was to find the extent to which the civic authorities were succeeding in producing water for domestic and public uses of a necessarily high quality and uncontaminated by the sewage, which perforce was disposed of in proximity. Twenty large sewage plants of different natures were visited in Great Britain. The water systems, while varying in smaller details, nearly all came under two general divisions of filtration, viz., mechanical and slow sand. Another feature, however, was observed in the ozone process utilized in Paris.

Windsor, Ont.—Governor Ferris, of Michigan, is personally urging the Governors of each State to name delegates to the Third American Road Congress, which will be in session at Detroit during the week of September 29th. Thirty Governors have named their delegates, and it is expected that a number of the governors will be present in person at the Congress. Governor McCreary, of Kentucky, which State has recently established a State Highway Department, expects to attend the meeting. It now seems assured that the heads of every State Highway Department from Maine to California will personally take part in the big meeting, and as a result of this unusual interest the demand for exhibit space by manufacturers has been unprecedented. All available space has been reserved by nearly one hundred manufacturers, who will display their products, including every kind of road-making machinery, engineering instruments, concrete machinery, bridges, culverts, concrete, wood block, asphalt, tar and oil preparations. Important progress is expected to be made in three great questions affecting the road movement. The Congress will endeavor to agree upon a policy of national aid, which, with the united support of the good roads workers throughout the country, will be submitted to the Congress of the United States. Steps will be taken at the session on State Road legislation, to be held under the auspices of the American Bar Association, to the formation through official action by the several states, of an interstate commission to codify and simplify existing State road laws. At present, most of the States are laboring under a weight of antiquated and contradictory road laws, and it is plain that the Commission will recommend simple, clear-cut and uniform road laws as a substitute for the mass of useless existing road legislation. Maintenance of roads will be discussed from every standpoint during the sessions held by the American Highway Association, the parent organization in the Congress, and the engineers will endeavor to determine among themselves upon the steps which should be taken in the several States to insure adequate maintenance.

Winnipeg, Man.—Considerable discussion has taken place in regard to what can be done by municipalities in the construction of good roads under the Good Roads Act, chapter 73, of the Statutes of Manitoba, 1912. Under this Act a municipality can issue debentures at a rate of interest not exceeding 5 per cent., spread over a period of forty years or less, which have to receive the approval and consent of the electors of the municipality in the usual way of all by-laws, and the interest on which is guaranteed by the Government, in order to insure the better sale of the debentures. The Government provides the municipality with an engineer, upon receiving a proper request by resolution of the council to do the engineering work for the municipality, lays out the roads, makes recommendations as to same, gives estimate of the cost, likewise of all bridges to be made, and generally furnishes the municipality with plans for the development of roads coming under the Act. The Government also co-operates with the municipalities in every way in order to assist them to bring their municipality under the Act, furnishing them free all engineering services, making plans, estimates, and carrying out the work of construction. By taking advantage of this Act taxpayers will find that the actual cost of construction may possibly be lessened, and by the issue of debentures payable in a long term of years the present taxpayer does not have to pay for all work done, but

any additional settlers coming to the district have to bear their fair proportion of the taxes. Thus, the taxpayers only pay a small amount of the principal and a small rate of interest, and have the satisfaction of obtaining good roads through the district almost immediately. The present system of patchwork will be found, upon investigation, to be much more costly than to go right ahead and construct a road system on thoroughly up-to-date and modern lines.

Ottawa, Ont.—The following recommendation of the board of control was passed at a recent meeting: "On the advice of the city engineer the board recommends that in future, to avoid the sinking of permanent roadways over excavations, no permanent pavements be laid until six months after sewers and other underground works have been completed; and, further, that the city clerk notify all public service companies that should they neglect to take advantage of the city engineer's notice from time to time of contemplated pavement works, and proceed with any repairs or new work which may require trenching the streets, permission thereafter will be refused." It was explained by the mayor that the city engineer was of the opinion that much of the faulty pavement of the past was due to not giving the roadway sufficient time to settle after it had been dug up when installing underground services. Some objection was raised to the recommendation, because it will mean a great deal of delay, as, for example, O'Connor Street has been dug up in a number of places recently, and if six months is allowed for the ground to settle again, it will mean that the paving can hardly go on this fall. Ald. McNeill thought that it should not apply to O'Connor Street. Practicaly all the members of the council were agreed, however, that it is better to wait than put down pavements that soon get out of repair because of the ground underneath settling.

Regina, Sask.—The civic construction works are proceeding very rapidly, an effort being made to complete the entire programme mapped out during the early part of the year. The sewer work is now well on toward completion, with the exception that about half a mile or so of trunk sewer still remains to be laid. Practically all of the street car line extensions to be completed this year are completed, while large gangs are employed on paving and laying concrete sidewalks. During the past week or two good progress has also been made on the construction of the federal armories at Regina. The steelwork has practically all been erected with the exception of that required to support the roof, and a large force of bricklayers are working at building the walls.

PERSONAL

J. E. RITCHIE, B.A.Sc., has been appointed permanent secretary of the University of Toronto Engineering Society.

C. W. LEAVITT, of New York, has been engaged by the city of Berlin, Ont., as civic expert to prepare a plan of the city.

F. W. SEIBERT, B.A.Sc., D.L.S., is now connected with the Department of the Interior, topographical survey's branch, at Edmonton, Alta.

RAYMOND UNWIN, a town planning expert of England, has completed preliminary work in connection with a housing scheme for Halifax, N.S., and has returned to London.

J. E. PENNYBACKER, chief statistician of the United States Joint Congressional Committee on Federal Aid, and secretary of the American Highways Association, has received an appointment to organize a Canadian statistical road bureau.

A. T. LAING, B.A.Sc., lecturer in highway engineering, and secretary, Faculty of Applied Science and Engineering, University of Toronto, has returned from a trip to Italy, France, Switzerland and Great Britain, where he has made a study of road conditions.

K. L. AITKEN, formerly general manager of the Toronto Hydro-Electric system, and under whose direction the system was designed, constructed and placed in operation, has returned from Europe and is re-establishing in Toronto his practice as consulting engineer.

R. G. BLACK, consulting engineer, has been appointed a member of the Toronto Hydro-Electric Commission to fill the vacancy caused by the resignation of H. L. Drayton, K.C., who accepted the chairmanship of the Dominion Railway Board last spring. Mr. Black is a University of Toronto man, with a broad, general experience in electrical engineering. The Commission, as now constituted, is P. W. Ellis, chairman, H. C. Hocken and R. G. Black.

OBITUARY.

H. BODE and E. R. ROBERTS, of the Canadian Boundary Survey staff, were killed in a landslide which occurred on September 6th, destroying their camp at Cape Musson, Dale Island, Alaska. The party had been working on the boundary survey up Portland Channel and Dixon Entrance.

GEORGE STREET, of the Dominion Government Survey staff, and his companion, H. V. RADFORD, of Washington, met death last year at the hands of an Eskimo band at Bathurst Inlet. The two men were engaged in coastal survey work, and had been away several years, eventually intending to follow the coast of Canada across the Arctic to the Yukon and thence south to Vancouver. The news of their sad fate did not reach headquarters for fully a year after the occurrence.

COMING MEETINGS.

ILLUMINATING ENGINEERING SOCIETY.—Annual Convention to be held at Pittsburg, Pa., September 22nd to the 26th. Secretary, I. D. Israel, 29 West 39th Street, New York City.

AMERICAN ROAD CONGRESS.—Annual Session will be held in Detroit, Michigan, from September 29th to October 4th. Secretary, J. E. Pennybacker, Colorado Building, Washington.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—Twentieth Annual Meeting to be held in Wilmington, Del., October 7th to 10th. Secretary, A. Prescott Folwell, 15 Union Square, New York.

UNITED STATES GOOD ROADS ASSOCIATION.—Convention will be held at St. Louis, Mo., November 10th to 15th. Secretary, J. A. Rountree, L021 Brown-Marx Building, Birmingham, Ala.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

20151—August 25—Authorizing the C.P.R. to construct a diversion of the surveyed trail in Secs. 23 and 14, Tp. 22, Rge. 3, W. 4 M,. and between Secs. 14 and 11, Tp. 22, Rge. 3, W. 4 M.; and to construct its tracks, by means of a grade crossing, across the said diversion in Sec. 14, mileage 102.2 on C.P.R. Bassano Easterly Branch.

20152—August 22—Authorizing the Essex Terminal Railway Company to construct its railway, at rail level, across the Langlois Road, and existing highway, being the boundary line between Twp. of Sandwich West and town of Ojibway.

20153—August 22—Ordering the C.L.O. & W. Railway to provide a cattle pass on the property of J. R. Irwin near Cobourg, Ont., of the same dimensions as that furnished by the C.N.R.

20154—August 22—Authorizing the Montreal Tramways Company to construct its proposed new track across the tracks of the G.T.R. on Notre Dame St., at the intersection of St. Ferdinand St., Montreal, Que.

20155—August 21—Authorizing the Winnipeg North Eastern Railway, to construct its line and tracks across the lines and tracks of the C.P.R. Co.'s Emerson Branch, in Roman Catholic Mission Lot 312, St. Boniface, Man.

20156—August 25—Authorizing the C.N.R. to construct its line of railway across the trail in the S.W. ¼ of Sec. 9, Tp. 7, Rge. 25, W. 4 M., Calgary South Branch, Alta.

20157—August 25—Authorizing the G. T. P. to construct bridge across Cottonwood Creek, at mileage 211.6 Wolf Creek West, District of Fort George, B.C.

20158—August 23—Approving revised location of Dominion Atlantic Railway, North Mountain Branch, between Grafton and Tory Lane, Tp. of Cornwallis, N.S.

20159—August 23—Approving plans showing location and details of D.A. Ry.'s proposed new station at Annapolis Royal, in Annapolis Co., N.S.

20160—August 22—Authorizing the Midland Ry. Co., C.P.R., C.N.R. and G.T.P. to operate their trains over the crossings within the scope of interlocking plant installed at said crossings.

20161—August 22—Authorizing the C.P.R. to construct a road diversion in Lot 10540, Kootenay Dist., B.C.

20162—August 22—Authorizing the C.P.R. to construct, maintain and operate a branch line of railway, or spur, for the British Columbia Sugar Refining Company, Limited, Regina, from a point on the existing spur in lane in Block 137, thence across said lane and across Lots 16 to 20 inclusive, Block 137, Regina, Sask.

20163—August 18—Approving location of C.N.R. Co.'s railway through Tp. 26, Rges. 23-26, west 3 M., Sask., mileage 105.42 to mileage 125.45, Alsask Branch.

20164—August 18—Approving revised location of G.T.P. Ry.'s main line of railway, mileage 138.19 to mileage 149.41, Prince Rupert East, through Squin-Lix-Stat Indian Reserve, Cassiar Dist., B.C.

20165—August 25—Granting leave to the C.P.R. to cancel siding agreement between the C.P.R. and the Nelson-Ford Lumber Company, dated July 17, 1909.

20166—August 23—Amending Order No. 19236 and providing that the Campbellford, Lake Ontario and Western Ry. and the C.N.R. build the bridge and approaches over its own line on the farm of John Pearse, in the S. ½ of Lot 4, Con. 4, Tp. Scarborough, Ont.

20167—August 19—Ordering that paragraph 1 of the operative part of Order No. 19500 be struck out; and that the plan dated Winnipeg, July, 1913, marked "A," showing the proposed layout at Herbert, Sask., be approved.

20168—August 25—Authorizing the G.T.P. to construct proposed bridge across Dome Creek, mileage 273, Wolf Creek West, Cariboo District, B.C.

General Order No. 109—Suspending, until further Order, the mileage rates on less than carload shipments of grain and grain products.

General Order No. 110—Requiring Railway Companies subject to the jurisdiction of the Board to accept and carry by freight, trunks containing wearing apparel and personal effects when securely corded.

20169—August 26—Approving revised location of G.T.P. Co.s main line from the west boundary of Lot 4900, into Fort George Indian Reserve, mileage 459.61 to mileage 466.11, east of Prince Rupert, Dist. of Cariboo, B.C.

20170—August 19—Authorizing G.T.P. Branch Lines Co. to construct, maintain, and operate a spur for the Lyall-Mitchell Company, turning out from its Melville-Regina Branch into Sixteenth Ave., thence easterly across Albert Street and the two tracks of the Regina Municipal Railway, and turning southerly into Wascana Park to the G.T.P. Hotel site in Regina.

20171—August 26—Authorizing the G.T.R. to construct, maintain, and operate branch line of railway, or siding, commencing at a point on the 13th Dist. of its railway on Lot No. 3, Con. 1, Tp. Caledon, Co. Peel, Ont., about one mile north of Inglewood Station, thence extending in a northerly direction to and into the premises of Charles Mould, Lot 3.

20172—August 19—Authorizing the G.T.R. to construct, maintain and operate, branch line of railway or siding and spur therefrom, commencing at a point on the G.T.R. west of Muskoka Wharf, Ont., thence extending in a northwesterly and northerly direction to the premises of the Ontario Granite Crushed Stone Company, Lot 8, Con. 4.

20173—August 26—Authorizing the G.T.R. to construct, maintain and operate branch line of railway or siding, commencing at a point on its railway south of Milton Station, Ont., thence extending in a westerly and northerly direction across Lot 14, 1st con., Tp. of Trafalgar, to and into the premises of Brandon's Pressed Brick and Tile Company, of Milton, Limited, on said Lot 14.

20174—August 26—Authorizing the G.T.R. to construct, maintain and operate branch line of railway, or siding, commencing at a point on its railway on Lot 13, 5th Con. of Tp. of Somerville, Co. Victoria, Ont., thence extending in a northerly direction to and into the premises of S. Suddaby on Lot 13, occupied by Messrs. Britnell and Company.

20175—August 26—Authorizing the Municipal Corporation of the town of Sudbury to construct and maintain, at its own expense, grade crossing over the C.P.R. Co.'s Soo Branch, Sudbury, at the intersection of Regent and Riverside Streets with the Copper Cliff Road.

20176—August 18—Authorizing the Corporation of the County of Richelieu to construct and maintain, at its own expense, a highway under the tracks of the Quebec, Montreal and Southern Railway Company. Parish of St. Joseph, Dist. of Richelieu, Que.

20177—August 26—Authorizing the New Brunswick Coal and Railway Company to construct bridge No. 1.1 on its line of railway.

20178—August 26—Approving location of extension Niagara, St. Catharines and Toronto Ry. Co.'s line to Lake Front, Lot 12, Con. 1, Tp. of Grantham, Co. Lincoln, Ont., mileage 0 to mileage 0.68.

20179—August 26—Approving location of C.N.R. station grounds at Bratton, Sask.

20180—August 21—Approving location of C.N.O.R. station grounds at Cedar Lake, Tp. of Deacon, Dist. of Nipissing, Ont., at mileage 163.06 from Ottawa.

20181—August 26—Approving revised location of C.N.R. Co.'s de Lourdes spur through Sec. 36, Tp. 6, Rge. 9, W. P M., Man., mileage 0 to mileage 2.627.

20182—August 26—Approving plans showing locations and details of Algoma Central and Hudson Bay Railway Co.'s station proposed to be erected at Frater, Dist. of Algoma, Ontario.

20183—August 23—Ordering the G.T.P. to erect fences and install cattle guards at the east end of its station grounds at Ingelow, in Sec. 4, Tp. 12, Rge. 16, W. P M., Man.

20184—August 19—Extending until the 30th October, 1913, the time within which the C.P.R. move and complete stock pens at Shelburne.

20185—August 25—Ordering the T.H. & B. Railway to employ a day and night watchman at the crossing of Bailey Street, Hamilton, Ontario, at its own expense.

20186—August 20—Relieving, for the present, the G.T.R. from providing further protection of the first highway one hundred and fifty feet west of St. Hilaire Station, Quebec.

20187—August 23—Amending Order No. 19957, dated Augnst 2nd, 1913, by adding thereto the following clause, namely:—

"And it is further ordered that the Applicant Company be, and it is hereby, authorized to re-arrange the remaining tracks of the Grand Trunk Railway Company on the property of the Acton Tanning Company, in the manner shown on the said plan, in green,—using for the purpose the rails, ties, and other track material in the existing spur tracks, and supply, at its own expense, such other material and labor as may be required for the purpose."

20188—August 18—Authorizing the Esquimalt and Nanaimo Railway Company to construct, maintain and operate siding for Scott and Peden from a point on its railway, near Victoria Station, B.C., thence crossing Store Street, Victoria, into the premises of Scott and Peden.

20189—August 26—Authorizing the Government of the Province of Saskatchewan to construct and maintain highway over the C.P. & G.T.P. Rys. in Sec. 28, Tp. 32, Rge. 27, W. 2 M., Sask.

20190—August 26—Approving proposed location of C.P.R. Co.'s station on the S.E. ¼ of Sec. 32, Tp. 6, Rge. 15, W. 4 M., at Conrad, Alta., at mileage 24.7 on its Suffield to Blackie Branch.

20191—August 27—Extending until 1st of November, 1913, the time within which the C.P.R. install gates at the crossing of Montcalm St., St. Boniface, Man.

20192—August 26—Authorizing the C.P.R. to construct additional track of its main line, Lake Superior Division, Cartier Subdivision, across certain highways in the Tp. of Balfour, Sudbury, Ontario.

20193—August 27—Approving location of C.P.R. station on land lying to the north of Wellington Street and westerly of Robinson Street, Port Butwell, Tp. Bayham, Co. Elgin, Ontario.

20194—August 19—Authorizing the C.P.R. to construct, maintain and operate branch line of railway or spur from a point on the existing spur in Lot D.G.S. 45, Parish of St. James, to and into the premises of the Pease Foundry Co., Limited, situate in Lot D.G.S. 45, Parish of St. James.

20195—August 18—Authorizing the C.P.R. to construct, maintain and operate branch line of railway or spur, for Peter Verigin, of the Doukhobor Society of Brilliant, B.C., from a point on the westerly limit of the C.P.R. Co.'s Slocan Lake Branch, mileage 19.75 from Slocan Junction, into Lot 3463 G 1, B.C.

20196—August 26—Authorizing the C.P.R. to construct, maintain and operate branch line of railway or spur for the East Kootenay Lumber Company, Jaffray, B.C., from a point on the easterly limit of the C.P.R. right-of-way at Glenlily, Alberta Division, in Lot 7927 Group 1, B.C.

20197—August 19—Authorizing the C.P.R. subject to the terms of city's consent, excepting paragraph 5, to construct, maintain and operate two branch lines of railway or spurs, from a point on C.P.R.'s line, thence across Lachine Canal Lands and St. Patrick Street, to and into the premises of the Canadian Rolling Mills Company, situate in Lot Cadastral No. 3607, Parish of Montreal, Emard Ward, Montreal, Que.

20198—August 26—Authorizing the C.P.R. to construct, maintain and operate branch line of railway or siding from a point on the existing spur in Lamoriciere Street, thence across said street and Cadastral Lots Nos. 209-100 to 209-105, inclusive, in village of Cote St. Louis, to and into the premises of the Canada Produce Company, situate in said lots in St. Denis Ward, Montreal, Que.

20199—August 22—Authorizing the C.P.R. to construct, maintain and operate branch line of railway or spur for Orr Minnis, Markdale, Ontario, from a point on the northeasterly limit of the C.P.R. right-of-way, at mileage 66.12, Owen Sound Subdivision, Ont. Div. to and into premises of Orr Minnis, Lot 100, village of Markdale, Tp. Glenalg, Co. Grey, Ont.

20200—August 26—Authorizing the C.P.R. to construct, maintain and operate extension of existing siding for Messrs. Quinlan and Robertson, in Lot 10, Con. 8, Tp. Huntingdon, Ont., at mileage 85.86, C.P.R.'s Havelock Subdivision, Ont. Division.

20201—August 19—Authorizing the C.P.R. to construct, maintain and operate branch line of railway or spur from a point on the existing spur in the lane in Block 206, thence across and along said lane in Block 206, Lethbridge, Alta., for the International Harvester Company of Canada, Limited.

20202—August 19—Authorizing C.P.R. to construct a diversion of the road allowance in Sec. 4, Tp. 21, Rge. 9, W. 4 M., and to construct its tracks by means of a grade crossing, across the diversion, at mileage 60.78 of the C.P.R. Co.'s Bassano Easterly Branch.

20203—August 27—Authorizing the Corporation of the city of Edmonton, Alta., to extend Peace Avenue across the Edmonton, Yukon and Pacific Railway, at rail level.

20204—August 27—Ordering the G.T.P. Branch Lines Company to construct its Prince Albert Branch across the highway in the S.E. ¼ of Sec. 4, Tp. 33, Rge.. 27, W. 2 M., at mileage 1.5, Sask., on or before September 15th, 1913.

20205—August 27—Authorizing the C.N.R. and G.T.P. Railways to operate their trains over, upon, or through the connection and junction of the C.N.R. with the National Transcontinental Railway at St. Boniface, Man.

20206—August 28—Authorizing G.T.P. Branch Lines Company to carry traffic over portion of its Biggar-Calgary Branch between Dodsland, mileage 48.0, and Loverna, mileage 104.06.

20207—August 27—Authorizing the Government of the Province of Saskatchewan to construct and maintain, at its own expense, road under the C.N.R. right-of-way in the S.W. ¼ of Sec. 21, Tp. 29, Rge. 17, W. 3 M., Sask.

20208—August 27—Ordering the C.N.R. to construct a standard portable passenger and freight shelter and platform and a two car cattle pen at Mulvihill, Man.

20209—August 28—Relieving, for the present, the C.N.O.R. from providing further protection at the crossing of Ontario Street, Cobourg, Ont.

20210—August 28—Authorizing the C.P.R. to construct, maintain and operate branch lines of railway or spurs for the Moose Jaw Flour Mills Limited, Moose Jaw, Sask., from a point on the N.W. limit of the right-of-way of the C.P.R. main line of railway in Block 102, Moose Jaw, thence across said Block 102 and Second Avenue, to and into the premises of the Moose Jaw Flour Mills, Moose Jaw, Sask.

20211—August 27—Authorizing the C.P.R. to construct, maintain and operate a branch line of railway or spur for the Sherwin-Williams Company, Winnipeg, Man., from a point on existing spur in lane in Blocks 65, 66, 68 and 69 and across 6th St. W, 7th Street W, 8th Street W, and 9th Street W, Calgary; and a branch line of railway or spur from a point on above spur in lane in Block 66, thence across said lane and 7th Street W., to and into the premises of the Sherwin-Williams Company, situate in subdivision Lots 39, and 40, Block 67, Calgary, Alta.

20212—August 28—Rescinding Order No. 17282, in so far as it approves the revision of the location between mileages 15.1 and 31.5; providing that if C.P.R. file with the Board a new plan showing a connection at mileage 19, the Board will approve the revision from mileage 15.1 to mileage 19.

20213—August 27—Authorizing the C.P.R. to construct, by means of grade crossings, additional track across certain highways in the District of Sudbury and Province of Ontario.

20214—August 27—Relieving the C.P.R. of speed limitation of fifteen miles an hour on the Lauder Extension of its railway from Tilson, mileage 28.7 to Alida, mileage 54.72.

20215—August 27—Approving revised location of portion of C.P.R. main line, as constructed, Lake Superior Division, Schreiber Subdivision, from mileage 16.01, thence in a westerly direction to mileage 21.79, Dist. of Thunder Bay, Ont.

20216—August 27—Authorizing the C.P.R. to change the present grade crossing in the road allowance between Lots 28 and 29, Con. 2, Tp. Scarboro, and to construct an additional track (double track) by means of a grade crossing, across road allowance between Lots 28 and 29, at mileage 89.0 on C.P.R. main line.

20217—August 27—Authorizing the C.P.R. to change the present grade crossing in the road allowance between Cons. 2 and 3, Tp. Scarboro, and to construct an additional track (double track), by means of a grade crossing, across said road allowance between Cons. 2 and 3, at mileage 88.2 on the C.P.R. main line.

20218—August 27—Authorizing the C.P.R. to change the present grade crossing in the road allowance between Lots 26 and 27, Con, 2, Tp. of Scarboro, and to construct an additional track (double track), by means of a grade crossing, across the said road allowance between Lots 26 and 27, at mileage 88.4, on the C.P.R. main line.

20219—August 28—Approving Express Classification for Canada No. 3, superseding and taking the place of the present Classification No. 2.

20220—August 28—Authorizing the city of Peterboro, Ont., to construct highway, known as De Laval Street, in said city, across the tracks of the Midland Branch of the G.T.R.

20221—August 28—Amending Order No. 19936 to provide that connection be made at the point shown on the C.N.R. Co.'s plan dated August 16, 1913, File No. 21826; provided the C.N.R. extend its transfer track up to the proposed connection with C.P.R.; the C.P.R. to put in crossover west of the new connection and extend its transfer track up to the proposed connection.

20222—August 26—Recommending to the Governor-in-Council for approval, the Rules and Regulations of the Transportation Department of the Montreal and Southern Counties Railway Company.

20223—August 29—Approving and authorizing the clearances at coaling station at G.T.R. new engine terminals, St. Lambert, P.Q.

20224—August 29—Authorizing the Corporation of the city of St. John, N.B., to construct a highway bridge over the Cantilever Branch of the C.P.R. at Alexandria St. Extension.

20225—August 29—Approving proposed location of C.P.R. station at Willows on the C.P.R. Weyburn Westerly Branch, in the South Half L.S. 12, Sec. 35, Tp. 7, Rge. 29, W. 2 M., Sask.

20226—August 29—Authorizing the C.P.R. to construct, maintain and operate branch line or spur for H. J. Heinz Company, Leamington, Ont., from a point on existing spur, thence across Con. St., to and into premises of H. J. Heinz Company, Subdivision Lot 27, Lot 2, Con. 11, Tp. Tillsonburg, Ontario.

20227—August 29—Authorizing the C.P.R. to construct, maintain and operate extensions to trackage for the Western Canada Flour Mills Company, Winnipeg, from points on the westerly limit of the right-of-way of the C.P.R. Manitoba Division, to and into premises of the Western Canada Flour Mills Company, situate in Lot D.G.S. "M" St. Boniface, Man.

20228—August 14—Authorizing the C.L.O. & W. Railway to divert the highway between Lots 8 and 9 of Con. B, Tp. Hamilton, Ont.; and authorizing the C.L.O. & W. Railway to construct its railway across the Cobourg and Grafton Road by means of a subway to be constructed on the line of the highway, carrying the said road under its railway and the two main line tracks of the G.T.R.

20229—August 26—Approving location of C.P.R. station proposed to be erected at Limerick on the C.P.R. Weyburn Westerly Branch, in the N.W. ¼ of Sec. 18, Tp. 8, Rge. 2, W. 3rd Mer., Sask.

20230—August 30—Authorizing the C.L.O. & W. Ry. to divert Fourth Depot River in Lot 12, Con. 8, Tp. Hichinbrooke, Co. Frontenac, Ont., and to construct a bridge across said river as so diverted at mileage 33.54 from Glen Tay.

20231—August 29—Extending the time within which the C.P.R. are required by Order No. 18512 to install gates at the North Vancouver Ferry, Columbia Avenue and the G.T.P. Railway Company's team crossing at Vancouver, B.C., until October 15, 1913.

20232—August 30—Amending Order No. 20102 by striking out the word "Sheffield" wherever the same appears in said Order and inserting in its place and stead the word "Suffield."

20233—September 2—Authorizing the C.P.R. to open for the carriage of traffic portion of the double track of its Swift Current Subdivision from Chaplin, near mileage 54, to Ernfold, mileage 66.5, Sask.

20234—September 2—Authorizing the C.P.R. to construct an additional track (double track) across highways at mileage 82.2 and 81.5, in the Province of B.C.

20235—August 30—Authorizing the Lake Erie and Northern Railway to construct its railway across certain highways in the Tp. of Oakland, Co. Brant, Ont.

20236—August 30—Authorizing the Lake Erie and Northern Railway to construct its railway across the highways in the Tp. of Townsend, Co. Norfolk, Ont.

20237—August 30—Approving location of the Lake Erie and Northern Railway Company from station 240+54 to station 850+54.8, Ont.

20238—September 2—Authorizing the C.N.O.R. to construct the lines and tracks connecting its Montreal-Port Arthur Line with the G.T.R. temporarily, pending the expiration of the lease from John Morrison, across Eganville Road, Tp. of Pembroke, Ont.

20239—August 30—Authorizing the C.N.O.R. to construct its proposed spur for Point Anne Quarries, Limited, across the public road between Lots 20 and 21, Point Anne Con., Tp. Thurlow, Ont.

20240—September 2—Authorizing the Government of Alberta to construct a highway across the C.N.R. in the N.E. ¼ of Sec. 30, Tp. 29, Rge. 20, W. 4 M.

20241—September 2—Authorizing the C.N.O.R. to construct its line of railway across public road between Lots 32 and 33, con. C, Tp. Scarboro, Co. York.

20242—August 30—Authorizing the C.N.O.R. to construct its line of railway across public road between Lots 30 and 31, Con. C., Tp. Scarborough, Co. York, Ont.

20243—September 2—Amending Order No. 20058 by striking out the words, "William Alexander of Silverwood," where the same appear in the recital to the said Order, and substituting therefor the words, "William Alexander Silverwood of Saskatoon."

20244—August 30—Authorizing the C.P.R. to construct, maintain and operate branch line of railway or spur for the Dunmore Development Company, Medicine Hat, Alta., from a point on the southerly limit of the right-of-way of the C.P.R. Alta. Div., thence across Block D. 1st Ave., Block A, and Gov. Trail, Mnn. Dunmore, Alta., to and into the premises of Dunmore Development Company, situate in Block E, S.W. ¼ Sec. 2, Tp. 12, Rge. 5, W. 4 M.

20245—August 30—Ordering that the effective date of the advanced rates in Supplement No. 17 to Tariff C.R.C. No. W-1615, be suspended for a period of Thirty days from the date of this Order.

20246—August 30—Ordering that the effective date of the advanced rate in Supplement No. 24 to Tariff C.R.C. No. W-1713 be suspended for a period of Thirty days from the date of this Order.

20247—September 2—Approving revision in grade of portions of C.P.R. main line from mile 6.35, at Farnham, thence in a north-westerly direction to mile 19.89 at St. Johns, P.Q.

20248—September 2—Relieving, for the present, the G.T.R. from providing further protection at the first public crossing one-quarter of a mile west of Colborne Station, Ont.

20249—September 2—Authorizing the Canadian Northern Alberta Ry. to construct its proposed spur to Jasper Park Collieries, Ltd., across the public road between Sec. 7, Tp. 49, Rge. 27, and Sec. 12, Tp. 49, Rge. 28, W. 5 M., Alta.

20250—August 30—Approving detail plans Nos. B-1174.1 and B-1174.2, showing bridge No. 112.0 over Wyandotte St., Windsor, Ont.

20251—September 2—Authorizing the Edmonton, Dunvegan and British Columbia Ry. to construct its line of railway across certain highways in the Province of Alta.

General Order—No. 111—Refusing application of Harold W. Riley, of Calgary, Alta., for reconsideration of Orders Nos. 17492 and 17384 prescribing express on cream and terms and conditions of service in connection therewith, and substituting certain rules for those included in tariff prescribed by Order No. 17384.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

RAILWAYS—STEAM AND ELECTRIC.

Calgary, Alta.—The announcement is made that work on the Dominion Western Railroad, which will run from a point on the international boundary line north of Great Falls, Montana, west into the Crow's Nest country, tapping the coal fields north to Calgary and on into the Peace River country, will be commenced immediately. British and American capital are back of the new undertaking.

+—Montreal, Que.—The Canadian Pacific Railway has awarded MESSRS. SOPER AND McDOUGALL the contract for the double tracking of eight miles of road from Levis to Chaudiere Junction and the extension of the yards at Levis to about double their present size.

Montreal, Que.—It is for the C.P.R. legal experts to take the next step in the fight with Maisonneuve over the laying of a spur line through that municipality. At present the laying of the rails is tied up through the Maisonneuve police interfering a short while ago, their action being sustained by the courts. Mr. Holden stated recently that he did not yet know what they would do to put the C.P.R. in the way of proceeding with the construction.

Victoria, B.C.—Steel is now being assembled for the construction of the splendid viaduct which is to span Arbutus Canyon on the route of the Esquimalt and Nanaimo Railway. As has already been announced the concrete piers for the structure have been in position for some weeks, and now that the other material has arrived, it will not be long before the trestle at one of the finest scenic bits between this city and Duncan will be an accomplished fact. The Arbutus Canyon bridge, however, is not the only construction work of that nature which is being undertaken by the Esquimalt and Nanaimo Railway, and their programme for the next year or so includes an extensive campaign of bridge construction along the route of the new east coast extension from McBride Junction to Courtenay. Among the spaces to be bridged on this route are French Creek and the Little Qualicum. Owing to the lateness of the arrival of the steel the Courtenay extension cannot be completed this year, but the work is being pushed through with all possible speed.

Victoria, B.C.—The work of grading the Canadian Pacific extension from Victoria as far as Union Bay will be finished by the end of November, according to Mr. Clarence Hoard, who has returned after a two weeks' trip of inspection. Mr. Hoard, who has a contract for the grading of the section between Courtenay and Union Bay, says that his men are busy on the concrete abutments and piers ready for the steel bridges which will be erected by the railroad company. There are two of these spans on this section, and the contractors will be ready for their erection at the end of the present month. "The twelve-mile section on this side of Courtenay is not quite so far advanced," said Mr. Hoard, "but I anticipate that the whole length of line will be turned over to the railway company before the end of November for the bridge spans and the actual laying of the track."

BRIDGES, ROADS AND PAVEMENTS.

+—Brantford, Ont.—The City Council has awarded the WARREN BITUMINOUS PAVING COMPANY the contract for the refacing of the pavement on Brant Avenue. The contract price is $1.22 per square yard.

+—Brantford, Ont.—The Town Council has awarded the following contracts in connection with pavements:—THE ROYAL ARTIFICIAL STONE PAVING COMPANY, of Guelph, were awarded the contract for the laying of a cement sidewalk on both sides of Aberdeen and Emily Street. Their tender was 11¼ cents per square foot. The work will be started at once. The company was also awarded the contract for the laying of a cement walk on Chester Avenue. The tender was 12½ cents. MR. GEO. THOMPSON was awarded the contract for laying a cement walk on the south side of Grand Street, Grandview. His tender was 13 cents per square foot.

Calgary, Alta.—The Calgary Builders' Exchange went on record as favoring reinforced concrete as the construction material for the proposed bridge across the Bow River to Crescent Heights. City Engineer Craig gave a detailed exposition of the bridge situation, dealing with the good and bad points of reinforced concrete. He discussed the advantage of both the high level and low level bridges, the latter as proposed by T. R. Mawson. The exchange was non-committal, not endorsing or condemning either plan.

+—Montreal, Que.—The contracts for the paving of Sherbrooke Street have been signed and work will be commenced at once, for the agreements call for the finishing of this improvement by October 26th next. It depends upon the weather whether this work can be done by that date. This thoroughfare will be paved in three sections. Two sections will be done by the BITULITHIC PAVING COMPANY, and one by the WARNER, QUINLAN COMPANY, and the total cost will be $214,797.50. While in Toronto the city council was shown some bitulithic pavement, and were pleased with it. The surface is rougher than asphalt, and is designed to enable the horses to get a better grip on it with their feet in frosty weather. The pavement to be laid by the Warner, Quinlan Company is an asphaltic composition, similar to

Barrett Specification Roofs

Economy *and* Protection

THE fire standards for theatre buildings are especially rigid. It is significant, therefore, that a large number of theatres throughout the country carry Barrett Specification Roofs. These roofs take the base rate of insurance and are acceptable to fire underwriters everywhere.

Their cost is less than that of any other permanent roof covering; they require no expenditure whatever for maintenance and usually last about twenty years.

A Barrett Specification Roof consists of five plies of tarred felt and pitch with a top covering of slag, gravel or tile. Being one continuous sheet with no laps or seams it blankets the flames in case of fire and will last until the supports beneath are entirely destroyed. From the standpoint of both economy and protection such roofs should be used on all permanent buildings.

A copy of the Barrett Specification with tracing, ready for incorporation into your building plans sent free on request. Address nearest office.

Special Note

We advise incorporating in plans the full wording of The Barrett Specification, in order to avoid any misunderstanding.

If any abbreviated form is desired, however, the following is suggested.

ROOFING — Shall be a Barrett Specification Roof laid as directed in printed Specification, revised August 15th, 1911, using the materials specified and subject to the inspection requirement.

bitulithic. In addition to Sherbrooke Street, the city will have paved under contract by the end of next month, a number of streets between St. Catherine, Ontario, and Sherbrooke. Among these are McGregor, St. Urbain, City Councillors, Clarke, Beaudry, Demontigny, at a cost of eight to eleven thousand five hundred dollars each.

+—**Ottawa, Ont.**—The Dominion Government has awarded MESSRS. JOHN DONOVAN and H. A. McCARTHY, Belleville, the contract for the construction of a new swing bridge over the Rideau Canal. The contract price is $10,380.

+—**St. Thomas, Ont.**—The Board of Works has awarded Mr. A. E. PONSFORD the contract for the construction of pavements on Elgin Street and Denison Avenue. The tenders were as follows:—Crowley and Macdonald, curb 30 cents, track work $2.75, pavement complete $1.20; A. E. Ponsford, curb 40 cents, track work $2.75, pavement $1.40; George Ponsford, curb 40 cents, track work $2.80, pavement $1.42.

Taghum, B.C.—Tenders will be received up till the 14th of October, 1913, for manufacture and delivery of superstructure, metal, bridge and tender for substructure and erection of superstructure bridge. Plans and specifications may be obtained from the Department of Public Works, Victoria, B.C. J. E. Griffiths, Public Works Engineer.

▲—**Toronto, Ont.**—Tenders will be received up till the 23rd of September, 1913, for the construction of a large number of sewers. Plans and specifications may be obtained from the Board of Control. H. C. Hocken, chairman.

Toronto, Ont.—Tenders will be received up till the 23rd of September, 1913, for the construction of a number of pavements, concrete curbings, and concrete walks. Plans and specifications may be obtained from the Board of Control. H. C. Hocken, chairman.

+—**Vancouver, B.C.**—The City Council has awarded the following contracts for the construction of pavements:—Fourth Avenue, from Vine to Balsam, T. R. NICKSON AND COMPANY, for creosoted wood block pavement, $13,839.76; track allowance, B. C. GRANITOID COMPANY. Fourth Avenue, Balsam to Alma Road, MESSRS. M. P. COTTON AND CO., for asphaltic mixture pavement, $124,841.76; track allowance, B. C. GRANITOID COMPANY. Burrard Street, Seaton to Pacific, COLUMBIA BITULITHIC, LIMITED, for asphaltic mixture pavement, $94,928.64. Wherever there was any track allowance the competing firms had entered bids both inclusive and exclusive of the track allowance, and the suggested arrangement was stated to be satisfactory to the contractors.

Victoria, B.C.—If the Canadian Mineral Rubber Company does not meet the notification to commence paving work on Gorge Road, and the intersections of Douglas Street and Hillside Avenue and on Government Street and Bay Street, the council will proceed with the work, leaving the surfacing to the Worswick Paving Company.

+—**Welland, Ont.**—The County Council has awarded MR. A. GOEBEL, Port Colborne, the contract for the construction of a bridge over Lyons Creek. The contract price is $1,500.

+—**Woodstock, N.B.**—The Canadian Pacific Railway has awarded MESSRS. McBEAN AND McLAGGAN the contract for the construction of the bridge at Meductic.

LIGHT, HEAT AND POWER.

Calgary, Alta.—Through an arrangement effected by Commissioner Graves the Calgary Power Company will enter into a five-year agreement with the city to supply power at $26 a horse-power per year, instead of at $28.50 as under the former agreement. The company will supply 5,000 horse-power a year, which will cost the city in the neighborhood of $130,000. Soon after the expiration of the old agreement last December, a new agreement was framed by R. A. Ross, the city's power expert, but the company contended that the penalty clause was too stringent and refused to sign it. The penalty clause in the new agreement calls for the company paying $52 per horse-power in case of breakdown, or twice the amount of the ordinary price of power. In case the city wants any more power than the 5,000 agreed to, it will be supplied at a dollar less per thousand than the regular agreement rate. The company will be able to supply as high as 5,000 horse-power when their new plant is in operation and their system of storage reservoirs is completed, but it is not likely that any demand for excess power will be made, as the city plant is capable of supplying 5,000 horse-power.

▲—**Regina, Sask.**—Tenders will be received up till the 1st of October, 1913, for supplying equipment for power-house. Plans and specifications may be obtained from E. W. Bull, Superintendent of Light and Power Commission.

▲—**Regina, Sask.**—Tenders will be received up till the 25th of October, 1913, for supplying equipment for power-house. Specifications may be obtained from E. W. Bull, Superintendent of Light, Heat and Power Department.

St. Catharines, Ont.—The cost of a Hydro-Electric plant in St. Catharines to equal the service now enjoyed is estimated by the Commission at $90,000 and $26,000 for a street lighting system. The council approved the proposition, but the fact that there was no estimate of the annual cost per hour to consumers was regretted by several aldermen. The city now has an offer of five cents per hour from the Cataract Company.

GARBAGE, SEWAGE AND WATER.

Montreal, Que.—The Board of Control and the Harbor Commissioners have met in conference in regard to the completion of the Elgin basin sewer and pumping house. The cost of the work has been estimated at $150,000, and the city and the Harbor Commissioners have consented to pay one-half each, pending the decision of the courts on the responsibility for diverting the sewage. No decision as to a future course of action was decided at the conference. The Board of Control has already recommended to the City Council that the city should purchase the adjoining properties.

+—**Port Edward, B.C.**—The Town Council has awarded the following contracts in connection with the installation of its water supply:—The DOMINION WOOD PIPE COMPANY, of New Westminster, the contract for supplying the pipe; MR. J. G. WATTS the general contract and building of the dam and the trenches. Messrs. Ritchie, Agnew and Company are the engineers in charge and the system will cost $25,000.

+—**Toronto, Ont.**—A contract for two 60″ pressure water filters has been awarded by O'Keefe's Brewery to WILLIAM B. SCAIFE & SONS, Pittsburg, Pa., who were the lowest bidders.

+—**Toronto, Ont.**—The Board of Control has awarded MESSRS. DONNELLY & GRAHAM the contract for the construction of sewers in Shaw and Arthur Streets. The contract price is 63c. per lineal foot for brick, and 62.23c. per lineal foot for concrete. The total cost is $356,000.

+—**Toronto, Ont.**—The city has awarded the MORAN CONSTRUCTION COMPANY, Ottawa, the contract for the midway sewer system outlet. The contract price is $89,416. MR. JOS. O. JEROW, Earlscourt, the contract for a drainage system. The contract price is $45,834.

Toronto, Ont.—Tenders will be received up till the 23rd of September, 1913, for the construction of a number of sewers. Plans and specifications may be obtained from the Board of Control. H. C. Hocken, chairman.

Toronto, Ont.—Tenders will be called for in about a month by the Department of Works, City Hall, Toronto, for the construction of a mechanical filter plant of sixty million gallons' capacity, to be built on the Island. About two months' time will be given to the filter firms to prepare their tenders. General specifications will be issued defining the Department's requirements, bidders to submit their own designs with their tenders. R. C. Harris is Commissioner of Works.

+—**Winnipeg, Man.**—The City Council has awarded the DOMINION CONSTRUCTION COMPANY the contract for the construction of a sewer in Lansdowne Avenue to McGregor Street.

INDUSTRIAL WORKS.

+—**Calgary, Alta.**—The Canadian Pacific Railway has awarded the J. L. McKINNEY Co. the contract for the earthwork on the big dam at Bassano. The contract calls for the sloping of the mile and a half bank at Horseshoe bend to prevent any possibility of a cave in. The bank at this point is steep and it is the intention of the C.P.R. to grade it down

MANNESMANN STEEL PIPE

FOUR STRONG POINTS:

1.—Our tubes can be bent cold on the spot without trouble.

2.—Our tubes can be supplied in lengths up to forty feet, thus effecting a large saving in joints, jointing material and labor.

3.—Leakage is reduced to a minimum, as the joints are far tighter and seventy per cent fewer.

4.—Saving in freight, etc., is considerable, as a steel tube weighs one-third to one-half as much as a cast iron pipe of the same length. And there are other convincing reasons and illustrations in our booklets.

BOOKLETS ON REQUEST

until it assumes a gradual slope. The work will take from six to twelve months to complete, and several million yards of earth will be moved by the contractors before the job is completed.

Calgary, Alta.—A syndicate of local and Minneapolis capitalists, of which Mr. O. G. Devonish is the head, will shortly commence the erection of what is declared will be the largest flour mill in the British Empire. It will be built in four units, to cost $1,400,000 each, and when all units are completed will have a capacity of six thousand barrels a day.

+—**Fort William, Ont.**—The Barnett-McQueen Company has awarded the SMART TURNER MACHINE CO., LIMITED, Hamilton, the contract for supplying an automatic feed pump and receiver.

▲—**Galt, Ont.**—Tenders will be received up till the 27th of September, 1913, for the construction of river walls. Plans and specifications may be seen at the office of the town clerk, Galt, Ont.

Gull Harbor, Man.—Tenders will be received up till the 7th of October, 1913, for the construction of an extension to the wharf at Gull Lake, Lake Winnipeg, Man. Plans and specifications may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

▲—**Halifax, N.S.**—Tenders will be received up till the 15th of October, 1913, for the construction of about 6,500 lineal feet of quay wall, foundations for buildings, sewers, dredging of harbor, and filling reclaimed areas. Plans and specifications may be obtained from Department of Railways and Canals, Ottawa. L. K. Jones, Assistant Deputy-Minister and Secretary.

Kaslo, B.C.—Tenders will be received up till the 7th of October, 1913, for the construction of a pile bent and timber decking wharf. Plans and specifications may be obtained from J. P. Ford, Esq., District Engineer, Revelstoke and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

+—**Lindsay, Ont.**—MR. A. E. KENNEDY, Bobcaygeon, has been awarded the contract for the construction of a wharf at Ancona Pt.

Moncton, N.B.—Maritime Oil and Gas Company have struck another big gas well in Albert County, near the scene of its present wells. The last well was several million capacity, and the well reported to-day at a depth of 1,640 feet, has a larger capacity.

+—**Montreal, Que.**—The Canadian Vickers Company, Limited, have placed an order with SIR WILLIAM ARROLS, of Clyde, for the construction of a gigantic shipuilding shed capable of accommodating a ship 880 feet long. A large order has also been placed for shipbuilding machine tools, of which British firms practically hold the monopoly.

+—**Montreal, Que.**—The Dominion Government has awarded MR. K. A. MORRISON, Ottawa, the contract for the concrete foundation and piers in connection with the Lachine Canal at St. Gabriel. The contract price is $14,433.75.

+—**Ottawa, Ont.**—The Department of Marine and Fisheries has awarded the contract to the POLSON IRON WORKS of Toronto for the construction of a steamer to be used on the St. Lawrence River above Montreal, and on Lake Ontario, in the lighthouse service. The contract price is $173,399. This is the first ship let under the new condition, namely, that construction must take place in Canada.

Ottawa, Ont.—Tenders will be received up till the 26th of September, 1913, for the renewal of the head pier, St. Anne's Lock. Plans and specifications may be obtained from the Department of Railways and Canals, Ottawa. L. K. Jones, secretary.

Ottawa, Ont.—For construction of the big shops of the Transcontinental Railway at Quebec, tenders will be submitted shortly. The cost will be around a couple of million dollars, and a number of big contractors are here figuring on specifications.

+—**Ottawa, Ont.**—The Dominion Government has awarded MR. J. R. BOULANGER the contract for the extension to Montmagny Wharf. The contract price is $5,000.

Ottawa, Ont.—Tenders are to be called at once for the erection of the two piers for outer harbor works at Victoria. The purchasing agent of the Department of Public Works has been ordered to proceed to Victoria at once in connection with the purchase of a site for the new drydock at Esquimalt.

+—**Port Arthur, Ont.**—The Canadian Pacific Railway has awarded the WESTERN DRYDOCK & SHIPBUILDING CO. the contract for the repairing of the steamers Alberta and Athabasca, which ply between this port and Port McNicol. Both steamers are to be completely fitted out with new boilers and accessories, while numerous other work calls for the overhauling of the engines and other general repairs. The contract price is $65,000.

Prince Albert, Sask.—Great mineral wealth is generally supposed to be embedded in the earth throughout the northwest provinces, and with the view of getting reliable data on this matter the board of trade at a recent meeting decided to ask the government to institute a thorough geological survey of the northern halves of Manitoba, Saskatchewan and Alberta.

+—**Quebec, Que.**—The Harbor Commission has awarded the POLSON'S IRON WORKS, Toronto, the contract for the construction of six scows. The contract price is $125,000. These are to be used in connection with the dredging of the Quebec Harbor, and are to be ready for delivery by the spring. In tendering for this contract the Toronto company were successful in competing with a number of the leading shipbuilding firms of both Canada and the United States.

Sarnia, Ont.—Improvements and additions to the plant of the Imperial Oil Company that will be made within the coming year are said to total upwards of three million dollars.

+—**St. Catharines, Ont.**—The Canadian Carbide Company has awarded the SMART TURNER MACHINE CO., LIMITED, Hamilton, the contract for supplying a centrifugal pump.

+—**St. John, N.B.**—The Dominion Government has awarded the METCALF CONSTRUCTION COMPANY the contract for the construction of grain conveyers. The conveyers will connect both the old and the new Canadian Pacific elevators with berths Nos. 5 and 6. They will be of the most modern design known to engineering science. They will consist of double belt galleries between towers with trippers and machinery for driving the conveyers, including heads, pails and snubbing pulleys and take-ups. There will also be 33 dock spouts. The motors for driving these conveyers will have a capacity of 465 horsepower. The contract price for the conveyers is $133,000, and a further allowance of approximately $5,000 is to be made for electrification. Work is to be begun immediately, and the conveyers are to be ready in time for the coming winter's business.

+—**Toronto, Ont.**—The Dominion Government has awarded the CANADIAN STEWART COMPANY the contract for another large section of the harbor improvement work. The contract price is $5,760,000. The latest contract includes the construction of a breakwater from the eastern channel to Woodbine Avenue, and the excavation of a ship channel 6,800 feet long and 400 feet wide from the eastern end of the harbor through the Ashbridge's Bay industrial district. This comprises the whole of the government works, except the three lift bridges which are to span the eastern and western channels and the ship channel.

Vancouver, B.C.—The end of the hard strata which the Pacific Coast Dredging Company encountered in their operations in dredging False Creek will not be reached until the machines have worked their way past Connaught bridge, according to Mr. Stuart-Cameron, general manager of the company. In order that no delay may be caused two more dredges will be placed on the job in another month, one of these being a hydraulic and one of the dipper type. No estimate of the amount of material taken from the channel has been made as yet but the figures will soon be ascertained.

+—**Victoria, B.C.**—The CANADIAN NORTHWEST STEEL COMPANY have been awarded the contract for supplying 200 tons of steel to be used in the construction of the new Pantages Theatre.

MISCELLANEOUS.

Alsask, Sask.—The ratepayers of this town have passed a by-law authorizing the expenditure of $6,000 for fire engine, hose and equipment, with a water storage tank and hose tower.

Aurora, Ont.—Tenders will be received up till the 24th of September, 1913, for supplying fire pumps, motors and auxiliaries, etc. Plans and specifications may be obtained from S. H. Lundy, Esq., town clerk.

Belleville, Ont.—Tenders will be received up till the 29th of September, 1913, for the erection of a new gun shed. Plans and specifications may be obtained from the Department of Militia and Defence. Ottawa. Eugene Fiset, Deputy-Minister.

+—Edmonton, Alta.—The Canadian Consolidated Rubber Company has awarded the CANADIAN STEWART COMPANY the contract for the erection of a warehouse. The contract price is $120,000.

Fort William, Ont.—Tenders will be received up till the 7th of October, 1913, for the construction of an examining warehouse. Plans and specifications may be obtained from Mr. H. E. Mathews, Winnipeg, Man.; Messrs. M. H. Beaden, Seaman and Penneman, Fort William, and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Grimsby, Ont.—Tenders will be received up till the 18th of September, 1913, for the erection of a cold storage warehouse. Plans and specifications may be obtained from the Department of Agriculture, Ottawa. A. L. Jarvis, secretary.

+—Halifax, N.S.—The Dominion Government has awarded MR. J. F. COISTON the contract for the erection of a new residence for the bacteriologist of the Department of Agriculture. The contract price is $9,600. MESSRS. D. M. THOMSON and A. C. THEAKSTON were awarded the contract for the erection of a laboratory building for the Halifax quarantine station. The contract price is $6,620.

+—Hamilton, Ont.—The Dominion Steel Castings Company has awarded H. G. CHRISTMAS & CO. the contract for additions to their plant. The contract price is $12,000.

▲—Kingston, Ont.—Tenders will be received up till the 30th of September, 1913, for the construction of extension to stables. Plans and specifications may be obtained from the Department of Militia and Defence, Ottawa. Eugene Fiset, Deputy-Minister.

Medicine Hat, Alta.—The building permits for the month of August amounted to $802,241. In the same month last year they amounted to $243,400. This is an increase of $558,841.

+—Montreal, Que.—The Board of Commissioners has awarded MR. J. L. SIMMONS the contract for the erection of a boiler house. The contract price is $6,225.

+—Montreal, Que.—Messrs. Sir W. G. Armstrong, Whitworth and Company, Limited, has awarded the following contracts in connection with the erection of their crucible steel plant. The contract for buildings, waterworks, and drainage systems, to MR. E. G. M. CAPE, Montreal; for supplying the steel, the DOMINION BRIDGE COMPANY; for supplying five 5-ton and one 15-ton cranes, the WHITNEY FOUNDRY EQUIPMENT COMPANY, Harvey, Ill.

+—Montreal, Que.—The John D. Metcalfe Company, Limited, has awarded E. F. GIHERSON & CO., LIMITED, the contract for supplying the Indiana limestone required for the following railway stations on the Campbellford, Lake Ontario and Western line of the C.P.R.: Whitby, Oshawa, Bowmanville, Port Hope, Brighton, Cobourg, Belleville.

+—Moose Jaw, Sask.—The School Board has awarded MESSRS. COLLUM BROS. the contract for the erection of Wadena School.

North Battleford, Sask.—The by-law to raise an additional $55,000 to finish and furnish the new collegiate institute has been carried here by a large majority over the required two-thirds.

+—Ottawa, Ont.—The Dominion Government has awarded MESSRS. CROCKETT & THARLE, Fort William, the contract for the construction of the addition to the Parliament Buildings. The estimated cost is $1,000,000.

Peterborough, Ont.—That the collapse of a wall carelessly built 50 years ago was the cause of the disaster at the Turnbull Department Store on August 28th last, and the death of five persons, was the opinion expressed by W. W. Langford at the inquest before Coroner Greer.

Peterborough, Ont.—The Canadian Pacific Railway will construct new freight yards and sheds here. The estimated cost is $16,000.

+—Regina, Sask.—The City Council has awarded the PARSONS CONSTRUCTION CO. the contract for the erection of a police station. The contract price is $211,050.

Regina, Sask.—An order-in-council has been passed at Ottawa authorizing the purchase of a site for a new customs building here. The estimated cost of the building is $200,000.

Regina, Sask.—The Gutta Percha Rubber Company will erect a warehouse in this city. The estimated cost is $30,000.

Sussex, N.B.—Tenders will be received up till the 22nd of September, 1913, for the construction of a drill hall. Plans and specifications may be obtained from the Department of Militia and Defence, Ottawa. Eugene Fiset, Deputy-Minister.

+—Toronto, Ont.—The HILL AND STRATHY CONSTRUCTION COMPANY, LIMITED, have been awarded the contract for the construction of a series of buildings. The contract price is $100,000.

+—Vancouver, B.C.—The Japan Trust Company has awarded the J. J. FRANZ CONSTRUCTION CO. the contract for the erection of a bank and office building. The contract price is $22,000.

+—Vancouver, B.C.—MR. S. BEAUMONT has been awarded the contract for the erection of a six-story reinforced concrete apartment building. The contract price is $35,000.

Vancouver, B.C.—The Canadian Pacific Railway have prepared plans for four additional storeys to the central portion of the $2,000,000 hotel. This work will cost in the neighborhood of $1,100,000.

Vancouver, B.C.—Plans have been approved by the city building department for additions to the Canadian Pacific Railway hotel here. These additions will cost $1,100,000.

+—Victoria, B.C.—The city has awarded MESSRS. KNOTT & JONES the contract for building the additions to the Old Men's Home.

+—Victoria, B.C.—The Provincial Government has awarded MESSRS. GILLES & STEPHENS the contract for the erection of South Lillooet school.

+—Victoria, B.C.—The Provincial Government has awarded MESSRS. ROBINSON BROS., New Westminster, the contract for the erection of the school at South Westminster. The contract price is $6,500.

Victoria, B.C.—Tenders will be received up till the 22nd of September, 1913, for addition and alterations to Soke School. Plans and specifications may be obtained from the Department of Public Works, Victoria. J. E. Griffiths, Public Works Engineer.

+—Welland, Ont.—The town has awarded MESSRS. CLARK BROS. the contract for the rebuilding of the county court house.

+—Winnipeg, Man.—The Metallic Roofing Company has awarded MESSRS. WORSWICK BROTHERS the contract for the erection of a warehouse. The contract price is $19,000.

+—Winnipeg, Man.—The Tribune Publishing Company has awarded MESSRS. HAZELTON & WALIN the contract for the erection of a publishing plant. The contract price is $173,000.

+—Winnipeg, Man.—Mr. E. Prain has awarded the DAYKIN SCOTT CONSTRUCTION COMPANY the contract for the erection of an apartment block. The contract price is $56,000.

+—Winnipeg, Man.—The T. Eaton Company has awarded MESSRS. CARTER, HALLS & ALDINGER the contract for the erection of a garage building. The contract price is $22,000.

+—Winnipeg, Man.—The Dominion Government has awarded MESSRS. CARTER-HALLS-ALDINGER COMPANY, the contract for the construction of a new drill hall. The contract price is $519,000.

CURRENT NEWS.

Edmonton, Alta.—Tenders for the $500,000 tunnel to be constructed for the Southern Alberta Land Company's monster irrigation project in the Lost Lake country, north of Taber, are now being called, and will close about the middle of the present month. This tunnel, which will be the largest for irrigation purposes in Western Canada, commences at a point three miles south of Lake McGregor, and extends along the lower end of the Snake Valley for nearly 10,000 feet. When completed, it is estimated by Divisional Engineer C. E. Bee, that it will carry 1,300 second feet, or 1,300 cubic feet will pass a given point every second. The tunnel will cut off five miles along the main ditch from the lake, which is the source of supply, and besides being the longest in the west for carrying water, it

A Combination in the Interest of Trade

Combinations in business are all right when they make for greater efficiency and better service to the public.

Our business is a combination of many businesses, or special lines, into a great "Departmental House for Mechanical Goods." We find by organizing our business along departmental lines that we can serve industrial Canada more efficiently, more economically and in a way that makes for the best interests of our customers.

You will find it a great convenience to deal with a House that can supply you practically anything you require in the mechanical line all "under one roof." One of the two items mentioned below may interest you

Elwell-Parker Electric Trucks

Wherever used have shown an actual saving of from 25 to 65 per cent., both for railroads and industrial concerns. One large Canadian plant trying electric trucks for the first time claims that each truck, operated by one man, has replaced eight men with eight wheelbarrows.

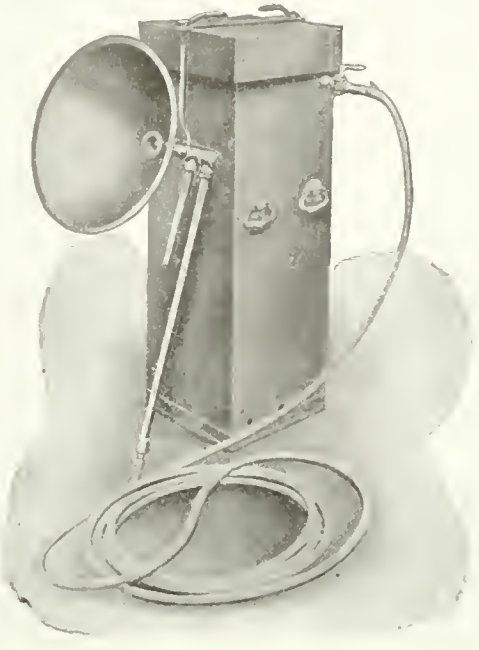
The truck shown above is one of the many types of Elwell-Parker Electric Storage Battery Trucks used by the American Express Co. The Canadian Pacific also use these trucks.

Elwell-Parker Electric Trucks are equipped with Edison Storage Batteries which are now recognized to be about the best on the market. Edison Batteries increase greatly the efficiency of the electric truck. We think so much of them that we would not advise you to purchase any electric truck that was not equipped with Edison Batteries.

Ellwell-Parker Trucks are extremely easy of operation, in no way requiring skilled labor, and by having a spare battery set can be worked continuously without injury.

If you are extending or rebuilding your plant it will pay you to investigate this well known truck.

Ask for Bulletin 107.



The Milburn Light

The No. 3-W Milburn Acetylene Light shown here gives from 5,000 to 12,000 candle power and lights 1,500 feet. The light follows the crane or shovel and throws its rays directly on the work. It lights instantly, requires no attention, and positively defies wind and weather. Has water tight cover and is made to withstand hard usage, the vibration and movement of cranes, steam shovels and dredges. Supplied with 15 inch aluminum reflector and 25 feet of armoured hose with connections. Cost 4 to 6 cents per hour to operate. Over 70,000 Milburn lights have been sold.

Ask for catalogue of Milburn Lights.

will be the largest in diameter, and will show a cross section of 100 square feet. Several engineers have already been out looking the proposition over, and owing to the magnitude of the scheme, bids are expected to be numerous. It will be at least a year before the company's land is opened up for settlement.

Fort William, Ont.—Rapid progress is being made on the various plants under construction here, nearly every man that can find room in which to work is being engaged, and indications are that the men in charge of the different works will complete their contracts on schedule time. The steel skeleton for the big car works is just about completed, and tile is already being laid at one end of the structure. About one-half of the steel frame work for the plant of the Steel Company of Canada, has been completed. A large force of structural iron workers are at work there. The building for the National Tube Works is complete, and the heavy machinery is arriving and being installed. Seven of the group of buildings that comprise the plant of the Fort William Starch Works, Limited, on Island No. 1, are about completed, and in two months' time it is expected manufacturing will have started. In anticipation of the demands that will be made on them for electrical energy by the new factories, the Kaministiquia Power Company is installing poles for power line to several of the new industries.

Naples, Italy.—The exact site of the harbor of Pompeii, for which search has been made for centuries, has been discovered by the sculptor Lorenzo Cozza, who has for years continued the investigations of his late father. The harbor is 1,250 yards inland from the beach as it at present exists, and 700 yards from the gate of Pompeii.

Toronto, Ont.—Ontario's mineral production for the first six months of this year, shows a large increase. From returns made to the bureau of mines, the gain in metalliferous ores amounts to about three and three quarter million dollars, the total being $18,598,804. Gold heads the list with a gain of $1,935,949, while silver shows a falling off of $242,867, and Cobalt and nickel oxides of $5,726. In addition to gold there is an increase of $96,176 in copper; $347,519 in nickel; $108,264 in iron ore, and $1,109,202 in pig-iron. These increases are all derived from comparisons with the production for the same period in 1912.

Winnipeg, Man.—The construction of a hall, to be called the Capitol Approach, 160 feet wide, from Portage Avenue due south to the central entrance to the provincial parliament buildings now under construction, the prolongation of Osborne Street north from Broadway to Portage Avenue, the closing of several streets (particularly that part of Colony between Portage and St. Mary's Avenue), with the opening of two new east and west streets, are features of a by-law which will come up for consideration of the city council. It is planned to organize an independent commission to handle the whole proposition, the bonds of which will be guaranteed by the Provincial Government and possibly by the city.

Washington, D.C.—An English builder has been awarded the contract for turbine drums for the newest American battleship, No. 39, at a little more than one-third the price offered by the lowest American bidder. The accepted bid, $57,436, was submitted by New York agents of the Cyclops Steel and Iron Works, Sheffield, England. It is exceptional for the navy department to send a contract abroad. but Acting Secretary Roosevelt held that the action was justified by the tremendous difference between the English and American prices. The Sheffield bid includes the payment of duty, and by giving the work to the foreign builder the United States save more than $100,000. There were two American bidders, the Bethlehem Steel Company, $169,568, and the Midvale Steel Company, $160,272. The Carnegie Company, the only other domestic concern equipped to build the drums, did not seek the contract.

Washington, D.C.—Canada has called upon the United States for aid in improving its highways, and J. A. Pennybacker, chief statistician of the joint congressional committee on federal aid in the construction of postroads, has been loaned to the roads committee of the Dominion. Mr. Pennybacker, who also is secretary of the American Highways Association, will organize a statistical bureau for the Canadian Commission. The Province of Ontario is said to have already appropriated $10,000,000 for the beginning of work on its highways, and the sum is to run up to five times that figure before the programme of improvement is completed.

TRADE ENQUIRIES.

The following inquiries relating to Canadian trade have been received:—907.—A well-known concern of Lyon would like to appoint a representative for the sale of their new patent universal rule for architect or engineers' drawings, answering all purposes. 909.—An Austrian firm of merchants seeks Canadian agents for the sale of hardware, glass and porcelain ware, electric lamps, fine art products, etc. Bankers' references given and required. 920.—A British firm in Yokohama would like to get into communication with exporters of wood sulphite, bleached and easy bleached, in Canada. 922.—A Birmingham firm is open to purchase large quantities of tinplate scrap. 926.—A large foreign firm in Japan would like to get in touch with manufacturers and exporters of sulphate of ammonia. 930.—Correspondence and quotation is requested by a Durban firm on handles of all kinds. The names of the firms making these inquiries, with their addresses, can be obtained upon application to:—"The Inquiries Branch, the Department of Trade and Commerce, Ottawa," or the Secretary of the Canadian Manufacturers' Association, Toronto, or the Secretary of the Board of Trade at London, Toronto, Brandon, Halifax, Montreal, St. John, Sherbrooke, Vancouver, Victoria, Winnipeg, Calgary and Chambre de Commerce du District du Montreal.

The following inquiries relating to Canadian trade have been received. 977.—A Hamburg firm of importers and exporters are constant purchasers of the copper, nickel, zinc, etc., ores and residues; they also desire to appoint a reliable representative in Canada for the sale of metals and of chemicals used for metallurgical purposes. 985.—A London firm who import railway ties, would be glad to receive offers from Canadian manufacturers of same. 987.—A Bristol firm desires to import mineral ores from Canada. 988.—A London manufacturing company who are buyers of cobalt oxide and grey arsenic, invites offers from Canadian producers.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W.

A Liverpool correspondent is prepared to communicate with Canadian manufacturers desirous of appointing United Kingdom sales agents.

From the branch office, 73 Basinghall Street, E.C.

A German company desire the addresses of Canadian firms who would be interested in purchasing pumps for waste and refuse water.

CANADIAN PATENTS JUST ISSUED.

Below will be found a list of patents recently granted to inventors in Canada, which is furnished by Messrs. Fetherstonhaugh and Company, patent barristers, solicitors, etc., head office, Royal Bank Building, 10 King Street East, Toronto. Offices in Hamilton, Montreal, Ottawa, Winnipeg, Vancouver and Washington, D.C., from whom all information may be readily obtained.

B. Bertram, capped gears; H. E. Reilly, mining boxes or columns; P. A. Barbeau, railway rail supports; W. B. Burton, rifle sights; J. V. B. Lamater, hot blast stump burners; R. B. Dillon, pole track extensions for litter carriers; L. Drapeau, electric signs; F. T. Goodwin, combined friction and positive clutches; R. H. Hill, devices for the transmission of power; C. C. Hockley, bark stripping machines; E. Johnson, stump pullers; A. Lappin, hand grip attachments; E. Maher, gate bars; A. M. Renney, fire guards; A. H. Rumohr, tenon machine gauges; H. E. Simpson, collapsible boxes; J. S. Speers, load binders.

The following are among the patents recently issued in Canada through the agency of Messrs. Ridout and Maybee, 59 Yonge Street, Toronto, from whom further particulars may be obtained:—

Leslie B. Taylor and Frederick Sanders, cartridges and tools to be used in their manufacture; James Dunlop, Quintin Marino, treatment of surfaces of aluminum or its alloys; David K. Morris and Geo. A. Lister, electric switches, circuit breakers, etc.; Alfred H. Darker, electrical installations for lighting, heating and ventilating railway carriages and similar purposes; Horace Mellnish and Alfred Montreuil, axes; Hugh H. Gregory, trailers for motor cars and other road vehicles; William Calway, building of concrete, cement and like walls.

When designing structures do you pay sufficient attention to the various matters that govern insurance rating? Why not use—without charge—the services of a well-known firm of

Insurance Engineers

Specializing in fireproof construction and protective devices

Not only can you add greatly to the fireproofness of buildings by adopting our suggestions, but it is very likely that you can do so without the improvements costing anything ultimately. They will practically be paid for by the lower insurance rates.

SECOND EDITION, Revised and Enlarged

River Discharge

By John C. Hoyt, Member, American Society of Civil Engineers, and Nathan C. Grover, Associate Member, American Society of Civil Engineers. 8vo. xii + 173 pages, 38 figures and 8 plates. Cloth, $2.00.

This book is of special use in connection with problems relating to the quantity of available water-supply, which is fundamental in all hydraulic development.

Water-Works Management and Maintenance

By Winfred D. Hubbard, Associate Member, American Society of Civil Engineers, and Wynkoop Kiersted, Member, American Society of Civil Engineers. 8vo, vi + 429 pages, 114 figures, 18 plates. Cloth, $4.00.

Part I. covers the various methods by which a supply is secured. Part II. covers the ordinary routine management of a water-works plant. Part III. is devoted to questions which arise in the dealings of municipalities with private water companies.

THIRD EDITION, Revised and Enlarged

The Filtration of public Water-Supplies

By Allen Hazen, Member, American Society of Civil Engineers. 8vo, xii + 321 pages, fully illustrated with line and half-tone cuts. Cloth, $3.00.

Explains the nature of filtration and the conditions which, in half a century of European practice, have been found essential for successful practice, with a view of stimulating interest in the subject, and of preventing the unfortunate and disappointing results which so easily result from the construction of inferior filters.

Hydraulics of Rivers, Weirs and Sluices

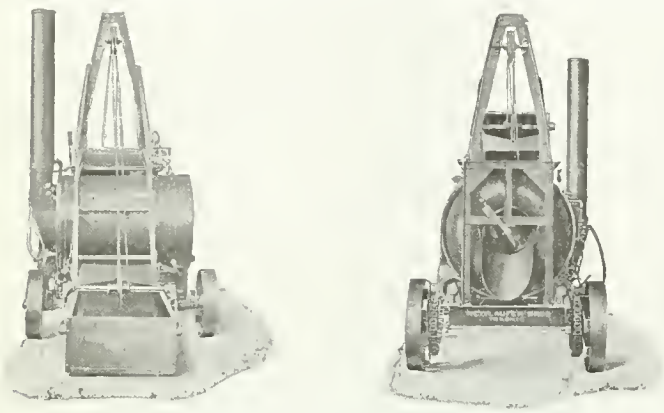
By David A. Molitor, C.E., formerly Professor of Topographic and Geodetic Engineering, Cornell University. 8vo. xii + 135 pages, 72 figures. Cloth, $2.00 net.

Treats on the derivation of new and more accurate formulae for discharge through rivers and canals obstructed by weirs, sluices, etc.

NEW STATIONARY DRUM MIXERS.

On account of the wide difference of opinion as to the respective merits of tilting and stationary drum mixers, Wettlaufer Brothers have announced they are now manufacturing their entire line of mixers with both tilting and stationary drums.

In loading the stationary drum mixer, the material enters the small, conical head of the drum, and on account of the heart shape immediately forces its way to the back. Fans,



New Traction Paving Mixer.—Views Showing Discharging and Loading Ends of Stationary Drum Mixer, made by Wettlaufer Bros.

or mixing blades, increase the mixing operation, so that the material is rapidly thrown from end to end, and the batch is held in the back of the drum ready for delivery.

The Wettlaufer automatic lift, or loading hopper, is attached to both stationary and tilting drum types of mixers. It holds the amount of the batch, with room for an additional foot or two. It loads the material directly into the mouth of the drum. To discharge the stationary drum mixers, all that is necessary is to turn a small handle. The mixers are constructed entirely of channel steel and semi-steel castings, the only wood in their construction being the engine platforms.

NEW INCORPORATIONS.

Victoria, B.C.—Rubidge Mining Company, $10,000.

Ottawa, Ont.—La Mine D'Or Huronia, $1,000,000. C. Lafond, G. Morrisset, F. Giroux.

Edmonton, Alta.—Clark Cobb Engineering Company, $50,000. Alberta Chemical Rubber Company, $150,000. J. J Candy Manufacturing Company, $25,000.

Shawinigan Falls, Que.—La Compagnie Manufacturiere de Shawinigan Falls, $49,500. A. Brunelle, Three Rivers, G. Baril, J. Trepanier, both of Shawinigan Falls.

Montreal, Que.—Compagnie Nationale de Construction, $49,000. J. Brosseau, G. E. Lanthier, both of Montreal, J. A. Croteau, of Thetford Mines. Specialties, $200,000. E. R. Bouchard, D. R. Kennedy, J. R. Perreault.

Toronto, Ont.—Koohinoor Gold Mines, $2,000,000. S. King, A. Hayward, F. Watts. Moffat-Irving Steel Works, $100,000. J. W. Moffat, T. C. Irving, junr., T. R. Loudon. Hepburn and Disher, $150,000 (iron and steel manufacturers). J. T. Hepburn, C. T. Disher, C. Inrig.

GIANT ELECTRIC CLAM-SHELL OUTFIT FOR CITY OF NEW WESTMINSTER, B.C.

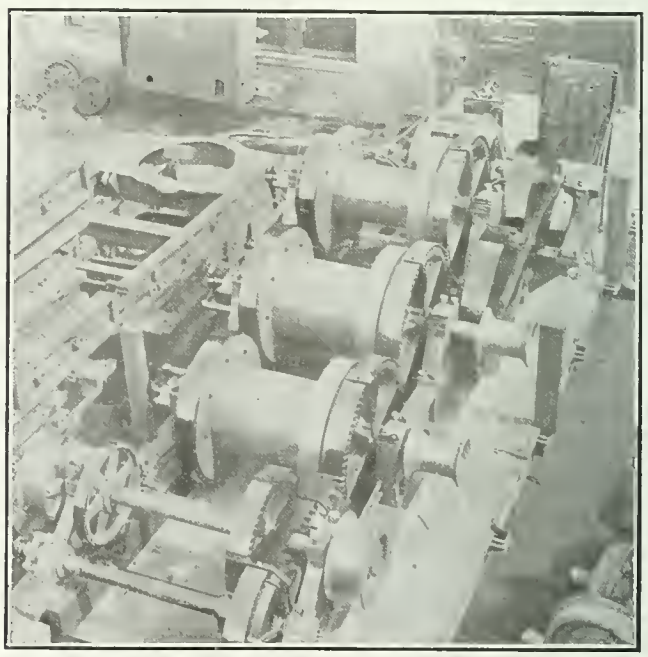
The city of New Westminster, B.C., has purchased an exceptionally large 150 h.p. electric hoist for operating a clam-shell bucket on a derrick. The hoist has three drums arranged according to the "waterfall" type, and is also equipped with a Clyde "Type A" Bull-Wheel Swinger. All drums have 18-inch barrel, the middle drum and the third being lagged to 24-inch. Fig. 1 illustrates the arrangement.

All gearing is of cast-steel, the motor pinion and intermediate gears having cut teeth with special dust-proof casing, and all drum gears are pressed on their shafts.

Specifications call for a pull of fifteen thousand pounds at two hundred and fifty feet a minute on a 24-inch drum. Each drum is equipped with brake band on the end opposite friction, and also with ratchet and pawl.

The length overall, of the hoist, including swinging gear, is 20 feet; width, over bearings of hoist, is 66 inches. The weight of the hoist alone is 35,000 pounds; with operating system this is increased to 38,000 pounds.

The 150 h.p. motor is a 3-phase, 60-cycle, 220-volt induction motor with outboard bearing bolted to bed extension. It develops 720-700 revolutions per minute. The controller has a contractor panel which automatically throws in the resistance, making it impossible to start the motor above a safe speed.



In addition to foot-brakes, the hoist is equipped with the Clyde patent automatic mechanical brake. This brake is mounted on the end of the intermediate shaft; its function is to prevent backward rotation of the gearing in the event of an interruption to the current.

The outfit was made by the Clyde Iron Works of Duluth, for Messrs. Taylor and Young, of 513 Pacific Building, Vancouver, B.C., from whom it was ordered by the city of New Westminster.

MEXICAN EAGLE ASPHALT

TRADE MARK

Mountain Street, Winnipeg, Man., paved with Mexican Eagle Asphalt.

Mexican Eagle Asphalt is the purest asphalt on the market. It is also a favorite among city engineers for its high cementing value and ductility. That means that sheet asphalt pavements constructed with Mexican Eagle Asphalt take first place among permanent pavements. Because there is no doubt but that sheet asphalt is in general the most satisfactory pavement. Read the experiences of a few Canadian cities:

OTTAWA, ONT.

Five-sixths of the thirty miles of permanent pavement in Ottawa is sheet asphalt. The principal business and residential streets are paved with it. The city engineer's department says that, if properly constructed, asphalt has been found to be about the best pavement they can have. Ottawa has a great many streets constructed with Mexican Eagle Asphalt.

WINNIPEG, MAN.

Winnipeg has laid eighty-one miles of sheet asphalt since 1897, for all kinds of traffic. City Engineer Ruttan installed the first municipal asphalt paving plant in Canada. In their experience the asphalt has worn uniformly and has been extremely satisfactory, particularly the pavements constructed with Mexican Eagle Asphalt.

VICTORIA, B.C.

Sheet asphalt is practically the only kind of pavement laid in Victoria, only four out of the forty-eight miles of permanent paving being of any other type. It has been Victoria's experience that no repairs at all are necessary in the first five years, and extensive repairs are necessary only after ten years' wear.

TORONTO, ONT.

As in most cities, asphalt predominates in Toronto, over 157 miles of sheet asphalt pavement having been laid since 1887. The average cost of maintenance per square yard during ten years has been only slightly over five cents a year. For both residential and business streets it is the principal pavement. One of the many Toronto streets that are laid with Mexican Eagle Asphalt was illustrated in last week's issue of The Canadian Engineer.

LONDON, ONT.

The city engineer of London says that asphalt pavements in London that have been down nine years are in good shape and will likely be so for another four or five years. Of less than nine miles of pavement in London, over five miles are sheet asphalt.

HAMILTON, ONT.

Thousands of tons of Mexican Eagle Asphalt have been used in Hamilton during the past five years. Asphalt greatly predominates there, two-thirds of the thirty miles of permanent paving being sheet asphalt. The principal business streets are paved with it. The average cost of maintenance per square yard for the first five years has been two cents a year.

TRANSPORTATION BUILDING — MONTREAL

TENDERS CALLED FOR

NOTICE TO CONTRACTORS.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, up to noon on Tuesday, September 23rd, 1913, for the construction of the following sewers:—

Earlscourt drainage system, No. 3 outlet.

Dufferin Street, 500 feet N. St. Clair Avenue to 90 feet N. Morrison Avenue.

Beaver Avenue, Lightbourne Avenue to 431 feet west.

Brandon Avenue, Primrose Avenue to Dufferin Street.

Lane 1st W. Christie Street, Garnet Avenue to Yarmouth Avenue.

Lane 1st E. Parliament Street, Spruce Street to Carlton Street.

Lane 1st W. Spadina Avenue, Oxford Avenue to N. end.

Lane 2nd N. Bloor Street, Symington Avenue to Perth Avenue.

Lane 1st N. Bloor Street, Bartlett Avenue to Gladstone Avenue.

Elmer Avenue, Queen Street to Norway Place.

Ashdale Avenue, Queen Street to Applegrove Avenue.

Wilton Avenue, storm overflow sewer section No. 3.

Danforth Avenue, storm overflow sewer section No. 1.

Bloor Street, Keele Street to E. limit of former West Toronto.

Morrison Avenue, Dufferin Street to Harvie Avenue.

Lane 1st N. Queen Street, Fuller Street to West end.

Envelopes containing tenders must be plainly marked on the outside as to contents.

Specifications may be seen and forms of tender obtained at the office of the Commissioner of Works, Toronto.

Tenderers shall submit with their tender, the names of two sureties (approved of by the City Treasurer, not members of the City Council, or officers of the Corporation of the City of Toronto) or in lieu of said sureties, the bond of a Guarantee Company approved of as aforesaid.

The usual conditions relating to tendering as prescribed by the City by-law must be strictly complied with.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman, Board of Control.

Toronto, September 11th, 1913.

TOWN OF GALT.

TENDERS FOR RIVER WALLS.

Sealed alternative tenders addressed to the Town Clerk, Galt, Ontario, and endorsed, "Tenders for River Walls," will be received until noon of **Saturday, September 27th, 1913,** for the construction of:—

(1) A concrete retaining wall, reinforced, 680 feet in length, approximately, along the westerly bank of the Grand River, from Main Street to Blair Road.

(2) A gravity retaining wall, reinforced, 680 feet in length, approximately, along the westerly bank of the Grand River, from Main Street to Blair Road.

Plans and specifications may be seen at the office of the Town Clerk, Galt, Ontario, after Friday, September 19th, 1913.

Each tender must be accompanied by a marked cheque, payable to the order of the Town of Galt for 5 per cent. of the amount of the tender. The corporation of Galt does not bind itself to accept any or the lowest tender.

CHAS. D. CAMPBELL,
Galt, Ont., September 17th, 1913. Town Clerk.

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

CANADIAN GOVERNMENT RAILWAYS.

Halifax Ocean Terminals Railway, Halifax, N.S.

Sealed tenders addressed to the undersigned and endorsed "Tender for docks, First Unit, Contract No. 3, Halifax Ocean Terminal," will be received at this office until twelve o'clock noon, Wednesday, the fifteenth day of October, 1913, for the construction of about 6,500 lineal feet of quay wall, foundations for buildings, sewers, dredging of harbor to a depth of 45 feet at low water, and filling reclaimed areas.

Plans and specifications and form of tender may be seen and full information obtained at the office of the General Manager, Moncton, N.B., at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Superintending Engineer, Halifax, N.S.

The right is reserved to reject any or all tenders.

By order, L. K. JONES,
Assistant Deputy-Minister and Secretary.
Department of Railways and Canals,
Ottawa, September 2nd, 1913.

DEPARTMENT OF MILITIA AND DEFENCE.

Extension to Stables, Tete-de-Pont Barracks, Kingston, Ont.

NOTICE TO CONTRACTORS.

Sealed tenders, marked on the envelope, "Tender for Construction of extension to stables, Tete-de-Pont Barracks, Kingston," and addressed to the Director of Contracts, Department of Militia and Defence, Ottawa, will be received until noon, September 30 instant, for the construction of an extension to the stables at Tete-de-Pont Barracks, Kingston, Ont.

Specifications may be seen and full particulars obtained at the offices of the Officer Commanding the 3rd Division, Kingston, Ont., and the Director General of Engineer Services, Headquarters, Ottawa.

Tenders must be made on the form supplied by the Department of Militia and Defence, and accompanied by an accepted cheque on a Canadian Chartered Bank, for ten per cent. (10%) of the amount of the tender, payable to the order of the Honorable the Minister of Militia and Defence, which amount will be forfeited if the party tendering declines to enter into or fails to complete the contract in accordance with his tender.

The Department does not bind itself to accept the lowest or any tender.

EUGENE FISET, Deputy-Minister.

Ottawa, September 2, 1913.

Newspapers will not be paid if this advertisement is inserted without authority from the Department.—47356.
H.Q. No. 44-7-73.

CITY OF REGINA, SASK.

Sealed tenders, registered and clearly marked on the outside of the envelope "Tender for Power-House Equipment," and addressed to the City Commissioners, Regina, Saskatchewan, will be received up until noon of October 25th, 1913, for the supply of:—

One 3,000 k.w. steam turbine, with condenser.

One 25-ton capacity, hand power crane for 45-foot span.

Specifications may be obtained from E. W. Bull, Superintendent of Light and Power Department, Regina, Saskatchewan.

A marked cheque for 5 per cent. (five per cent.) of the amount of bid must accompany tender.

The City Commissioners reserve the right to reject any or all tenders.

PERMANENCE—

an ideal that is now attainable

THE superiority of concrete over all other materials for the building of permanent structures is now generally admitted.

The next step towards ideal construction, is to realize that for satisfactory concrete work, it is necessary to use a cement that is uniformly high-grade

CANADA Portland CEMENT

is the selection of the leading engineers, architects and contractors. Their experience has proved that in this brand they can obtain a certainty of success.

With concrete coming into more and more general use for the construction of buildings, bridges, viaducts and highways, it is vitally important that those in authority on such matters should select the best materials obtainable.

Use the cement that our best architects and engineers have selected for their most important undertakings. Select Canada Cement — it costs no more than any others.

MARKET CONDITIONS

Montreal, September 13th, 1913.

Bar Iron and Steel.—Trade is reported active. Bar iron, $2.10 per 100 pounds; best refined horseshoe, $2.35; forged iron, $2.25; mild steel, $2.20; sleigh shoe steel, $2.20 for 1 x ⅜ base; tire steel, $2.30 for 1 x ⅜ base; toe caulk steel, $3; machine steel, iron finish, $2.25.

Cement.—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1.40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re-purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain.—The market is quoted per 100 lbs. as follows:—¼-in., $5.65; 5/16-in., $4.70; ⅜-in., $4.00; 7/16-in., $3.65; ½-in., $3.45; 9/16-in., $3.45; ⅝-in., $3.35; ¾-in., $3.25; ⅞-in., $3.15; 1-in., $3.05.

Explosives and Accessories.—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c, and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron.—The market is steady. Prices, basis, 28-gauge, are:—Queen's Head, $4.40; Colborne Crown, $4.20; Apollo, 10¾ oz., $4.30. Add 25c. per 100 lbs. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe.—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No 1 Summerlee, $22.50 per ton; selected Summerlee, $22; soft Summerlee, $21.50 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19.25 to $19.50 per ton, on track.

Lath.—See Lumber, etc.

Lumber, Etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $16. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph Poles: seven-inch top, cedar poles, 25-ft. poles, $2 each; 30-ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce, 4-ft. x 1½-in., mill run, $3 to $3.25; pine, 4-ft. x 1½-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2.10; XX, $2.40; XXX, $2.80.

Pipe.—Cast Iron.—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe.—Wrought and Galvanized.—Demand is fair and the market steady: —¼-inch $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ⅜-inch, $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent off for black, and 59 per cent. off for galvanized. The discount on the following is 72½ per cent. off for black, and 62½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 72½ per cent. for black and 62½ per cent. for galvanized:—2-inch, $36; 2½-inch, $57.50, and 3-inch $75.50; 72½ per cent. off for black, and 62½ per cent. of for galvanized; 3½-inch, $95; 4-inch, $108.

Toronto, September 17th, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron.—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel.—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates.—⅜-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes.—Orders continue active. Lap-welded, steel, 1¼-inch, 10c.; 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks.—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $13 to $15 per M., three grades.

Broken Stone.—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Robbie stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.25 for large, freight to Toronto, 60 cents.

Cement.—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot.—The market is lower at 15⅝ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps.—75c. and $1 per 100; case lots, 5,0000, 20 per cent. off.

Dynamite.—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¼ cents pound, 1 to 9-case lots, 50 lbs to case. For each additional 10 per cent. nitro-glycerine add 1¼c. per hundred. For 10-case lots and over deduct ½ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1½ cent.

Fuses.—Electric Blasting.—Double strength, $3.50 per hundred, advance 5c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 5c. per hundred for each 2-in. wire additional.

Iron Chain.—¼-inch, $5.75; 5-16-in, $5.15; ⅜-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3.55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe.—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40.60; 6-inch, $52.64. Galvanied Pipe, ¼-inch, $2.86; ⅜-inch, $2.86 ½-inch, $5.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead.—Firmer, $5.25 to $5.50.

Pig Iron.—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar.—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate.—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $6; green, $8, with a prospect of advance. Dealers are fairly busy.

Sand.—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe.—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0.25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00

P. & H. H. traps	2.00	3.20	6.50	15.00	.....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes, 9 inches and under or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels.—Active.—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2.75 to $3 per 100 pounds. Extra for smaller sizes of angles and tees.

Sheet Copper.—22c. per lb.

Sheet Steel.—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized.—Apollo Brand.—Sheets, 6 or 8 feet long, 30 or 36 inches wide; 10-gauge, $3.00; 12-14-gauge, $3.00; 16, 18, 20, $3.30; 22-24, $3.40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 pounds. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin.—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel.—Jowett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates.—3-16-inch, $2.40 per 100 lbs.

Zinc.—Spelter.—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, September 16th, 1913.

Anvils.—Per pound, 11½ to 12½c.; Buckworth anvils, 60 lbs. and up, 10½ to 10¾c.; anvil and vise combined, each $5.50.

Bar Iron.—$2.50 base.

Bars.—Crow, $4.50 per 100 pounds.

Beams and Channels.—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 90, 118, 119, 172, 132, 145, 176.

Brick.—Kiln run per M, $13; sewer per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland.—$2.40 to $2.50 per barrel.

Chain.—Coil, 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7-16, $4.75; ½, $4.50; 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5¾c. Tin out, 70 and 10 per cent.

Copper.—Tinned, boiler, 26½c., planished 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent discount.

Dynamite.—$11 to $13 per case.

Galvanized Iron.—Apollo, 10¾, $4.60; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20, $4; 18, $3.95; 16, $3.90; Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30; 22, $4.30; 20, $4.10 per cwt.

Iron.—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26-gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American, $5.15; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe.—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7.80; 1½-inch, $9.35; 2-inch, $12.50; galvanized—½-inch, $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch.—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled.—3-16-in., $3.35 base; machinery, $3 base; share, $4.50 base; share crucible, $5.50, cast share steel, $7.50; toe calk, $4.50 base; tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel.—8½ to 15c. per pound

BENDING MOMENTS IN FLAT SLABS

A MODIFICATION OF GRASHOF'S GENERAL BENDING MOMENT THEORY, FOR CONSIDERATION OF UNIFORMLY DISTRIBUTED LOAD—THE LACK OF SUFFICIENT REINFORCEMENT A COMMON DEFECT IN MANY FLAT SLAB SYSTEMS

By V. J. ELMONT, B.Sc., A.M. Can. Soc. C.E.

WITH very few exceptions, the flat slab systems in use show lack of adequate reinforcement. The designs are very similar, as regards insufficient reinforcing, to those adopted during the period 1885 to 1895 in the making of ordinary slabs and beams. As long as the tension was at the bottom side of a structure the steel was placed correctly, and in general it was also correctly placed over columns, but for slightly more complicated structures and stress distributions but little understanding was shown. A great number of "systems" existed, formed, as a rule, by adding a few bars, here and there, to the usual reinforcing. As these "systems" were able to carry a test load of as much as twice the live load without failing and with a deflection of only a small fraction of an inch, their inventors considered these structures to be a complete success and assured architects and others interested in buildings of strength, rigidity, economy, etc., of the inventions, by means of neat printed matter and pictorially illustrated advertisements, showing a pile of well filled bags resting on the structure. There was usually added a list giving the various jobs where the "system" had been employed. The excellence of the invention was thereby made clearly evident without question.

To-day theoretical and practical experience will veto most of these early "systems." The same veto should be placed on the majority of the flat designs now in use.

The thorough and scientific test loadings, made by the University of Illinois (Prof. Talbot) and others, of flat slab floors in actual structures have shown the insufficiency of their reinforcing in a practical way. Below it is shown theoretically.

In nearly all flat slab designs it is found that the positive bending moments and the negative moment over the columns are provided for, more or less successfully. The existence of these moments are, of course, easily recognizable, even by those whose knowledge of mechanics does not extend much beyond the stresses and strains in a simply supported girder or truss. But the negative moments perpendicular to the sides of the panels are, as a rule, entirely neglected, although they have about the same numerical value as the maximum positive moments.

The following calculations are based on Grashof's general theory* modified by the general assumptions on which all calculations for reinforced concrete depend. The method adopted follows one given in a recent issue of "Deutsche Bauzeitung."

For an infinite slab, of uniform thickness, h, supported at a series of points, dividing it into square panels of side, 2a, and uniformly loaded with q per sq. unit, Grashof gives the following values for the deflections, z, at the various points x, y:

$$z = \frac{g}{4 \cdot A \cdot h^3} \cdot [(a^2 - x^2)^2 + (a^2 - y^2)^2]$$

where $A = \frac{m^2}{m^2 - 1}$. E, m is Poisson's constant, and E the modulus of elasticity.

The origin of the system of co-ordinates lies at the middle point of the diagonal of the panel, the directions of the x and y axes being parallel to the sides.

The horizontal normal stresses c_x and c_y at the point x, y, v (that is, the point whose distance is v from the centerplane of the slab) are

$$c_x = -A \cdot v \cdot \left(\frac{\delta^2 z}{\delta x^2} + \frac{1}{m} \cdot \frac{\delta^2 z}{\delta y^2}\right)$$

and

$$c_y = -A \cdot v \cdot \left(\frac{1}{m} \cdot \frac{\delta^2 z}{\delta x^2} + \frac{\delta^2 z}{\delta y^2}\right)$$

From the equation for z it follows that

$$\frac{\delta^2 z}{\delta x^2} = \frac{g}{A \cdot h^3} \cdot (3x^2 - a^2)$$

and

$$\frac{\delta^2 z}{\delta y^2} = \frac{g}{A \cdot h^3} \cdot (3y^2 - a^2)$$

$$\therefore \quad c_x = -\frac{g}{h^3} \cdot v \cdot \left[3x^2 - a^2 + \frac{1}{m} \cdot (3y^2 - a^2)\right]$$

and

$$c_y^2 - \frac{g}{h^3} \cdot v \cdot \left[\frac{1}{m} \cdot (3x^2 - a^2) + 3y^2 - a^2\right].$$

The corresponding bending moments per unit width are

$$M_x = -\frac{g}{h^3} \cdot \frac{h}{2} \cdot \left[3x^2 - a^2 + \frac{1}{m} \cdot (3y^2 - a^2)\right] \cdot \frac{h^2}{6}$$

$$M_y = -\frac{g}{h^2} \cdot \frac{h}{2} \cdot \left[\frac{1}{m} (3x^2 - a^2) + (3y^2 - a^2)\right] \cdot \frac{h^2}{6}$$

or

*Theorie der Elastizität und Festigkeit, Berlin, 1878, page 358.

$$M_x = -\frac{g}{12}\cdot[3x^2 - a^2 + \frac{1}{m}\cdot(3y^2 - a^2)]$$

$$M_y = -\frac{g}{12}[\frac{1}{m}\cdot(3x^2 - a^2) + 3y^2 - a^2].$$

Taking m = 3,

$$M_x = -\frac{g}{12}\cdot(3x^2 + y^2 - \frac{4}{3}a^2)$$

$$M_y = \frac{g}{12}\cdot(x^2 + 3y^2 - \frac{4}{3}a^2).$$

These moments, parallel to the axes, can be shown to be the maximum moments, and the stresses c_x and c_y to be the maximum stresses in points x, y, $\frac{h}{2}$. The bending moments vary only with the value c of the normal stress in the upper and lower side of the slab

$$M = \frac{h^2}{6}\cdot c,$$

the question of the direction of the maximum bending moments is accordingly reduced to that of the direction of the principal stresses. To find these advantage is taken of the fact that the stress distribution is a "plane" one for all points in the plane $z = \pm\frac{h}{2}$; the normal stress c_z (parallel to the z-axis) can with sufficient accuracy be assumed O and furthermore the shear stresses $s_x = s_y = O$ for the same reasons as for an ordinary beam. The necessary and sufficient requirements for a plane stress distribution are thus fulfilled.

To fully determine the stresses in the points x, y, $\pm\frac{h}{2}$ it is now only necessary to know the values of the shear stresses s_z. Grashof gives

$$s_z = -\frac{m-1}{m}\cdot A\cdot\frac{h}{2}\cdot\frac{\delta^2 z}{\delta_x\cdot\delta_y}$$

As the equation for z does not contain any product of x and y, $\frac{\delta^2 z}{\delta_x\delta_y} = o$ and therefore $s_z = O$; consequently c_x and c_y derived above are the principal stresses at the point, and then again M_x and M_y the maximum bending moments.

The distribution of the bending moments over the entire slab is given by the equations for the bending moments; by substituting $\frac{1}{2}$ for a (l the span) the equations will take the form

$$M_x = -\frac{gl^2}{12}\cdot[3\cdot(\frac{x}{l})^2 + (\frac{y}{l})^2 - \frac{1}{3}]$$

$$M_y = -\frac{gl^2}{12}\cdot[(\frac{x}{l})^2 + 3(\frac{y}{l})^2 - \frac{1}{3}]$$

In the following table is given the bending moments for different values of $\frac{x}{l}$ and $\frac{y}{l}$

$\frac{x}{l}$ =

	0.x centre of slab	0.1	0.2	0.3	0.4	0.5
0.x	$+\frac{gl^2}{36}$	$+\frac{gl^2}{39.6}$	$+\frac{gl^2}{56.3}$	$+\frac{gl^2}{189}$	$-\frac{gl^2}{81.9}$	$-\frac{gl^2}{28.8}$
0.1	$+\frac{gl^2}{37.1}$	$+\frac{gl^2}{40.9}$	$+\frac{gl^2}{59}$	$+\frac{gl^2}{225}$	$-\frac{gl^2}{76.7}$	$-\frac{gl^2}{28.1}$
0.2	$+\frac{gl^2}{40.9}$	$+\frac{gl^2}{45.6}$	$+\frac{gl^2}{69.3}$	$+\frac{gl^2}{514}$	$-\frac{gl^2}{64.3}$	$-\frac{gl^2}{26.3}$
0.3	$+\frac{gl^2}{49.3}$	$+\frac{gl^2}{56.3}$	$+\frac{gl^2}{97.3}$	$-\frac{gl^2}{450}$	$-\frac{gl^2}{50.7}$	$-\frac{gl^2}{23.7}$
0.4	$+\frac{gl^2}{69.3}$	$+\frac{gl^2}{83.8}$	$+\frac{gl^2}{225}$	$-\frac{gl^2}{124}$	$-\frac{gl^2}{39.1}$	$-\frac{gl^2}{20.8}$
0.5	$+\frac{gl^2}{133}$	$+\frac{gl^2}{225}$	$-\frac{gl^2}{327}$	$-\frac{gl^2}{64.3}$	$-\frac{gl^2}{33}$	$-\frac{gl^2}{18}$

(Over column)

The bending moments parallel to, and along the sides of the panel are thus positive at the middle point and equal to $+\frac{gl^2}{133}$ (see last line of table), decreasing to $-\frac{gl^2}{18}$ over the support; perpendicular to the sides the bending moments are negative (last column) over the entire length, $-\frac{gl^2}{28.8}$ at the middle point and $-\frac{gl^2}{18}$ over the support.

As the above calculations are based on a uniformly distributed loading, the negative moments derived therefrom can be considered as the maximum values for which the slab has to be dimensioned. The positive moments attain their maximum by partial loading. Judging from similar cases (continuous slabs and beams) it seems reasonable to assume that the maximum positive moment from a live load p per square unit will be

$$2\cdot\frac{pl^2}{36} = \frac{pl^2}{18},$$

$\frac{pl^2}{36}$ being the maximum moment at the centre of the slab for a uniformly distributed load. The resulting moment from a dead load g per square unit and live load p per square unit would therefore be

$$M = \frac{gl^2}{36} + \frac{pl^2}{18}$$

or for values of g varying from $\frac{3}{4}$p to $\frac{1}{2}$p, which covers nearly all practical cases, the maximum positive bending moment can be taken as

$$M = \frac{gl^2}{22},$$

where g is the total load per square unit (g = g + p).

Above Poisson's constant, m, has been taken equal to 3 which, according to the not very numerous experiments made so far on this continent and on the other side of the ocean, seems a fair figure. That the value of m is not of great significance will be seen by the table below, which gives the maximum negative moment over the

columns, the maximum negative moment between the columns and the maximum positive moment at the centre of the slab for m, 2, 3 and 4:

	Maximum negative moment over col.	Maximum negative moment between col.	Maximum positive moment at centre.
	gl^2	gl^2	gl^2
m = 2	$\frac{}{16}$	$\frac{}{32}$	$\frac{}{19}$
	gl^2	gl^2	gl^2
m = 3	$\frac{}{18}$	$\frac{}{28.8}$	$\frac{}{22}$
	gl^2	gl^2	gl^2
m = 4	$\frac{}{19.2}$	$\frac{}{27.4}$	$\frac{}{23}$

RAIL FAILURE STATISTICS.

In a report recently submitted by the Rail Committee of the American Railway Engineering Association, statistics concerning rail failures in the United States for the year ended October 31st, 1912, are published. The data shows wide variation in results, which the committee claims must be due, to a large extent, to the lack of uniformity in the performance of different mills, and also to a lack of uniformity in the product of any individual mill.

The report shows also that the average performance of the heavy sections (85-lb. to 100-lb.) is not quite so good as that of the lighter sections (72-lb. to 80-lb.). The average rate of failure in the open-hearth rail is lower than that of the Bessemer, although both are higher than last year. The rate of failure of the open-hearth rail in 1912 was 22% higher than in 1911, and 40% higher than in 1910. The rate of failure of the Bessemer rail was 68% higher in 1912 than in 1911, and 56% higher than in 1910.

The rate of failure of the Bessemer rail was, in 1912, 116% higher than that of the open-hearth in 1911, was 58% higher, and in 1910, 94% higher.

A higher percentage of failures has occurred in rails from the upper part of the ingot than in those from the lower positions.

For the past four years, head failures have predominated except in 1912, in which year there was a slightly higher percentage of broken rails. It will be remembered that the early part of 1912 was marked by exceptionally severe weather which was accompanied by an epidemic of broken rails. The committee regards this as an abnormal condition, however, and maintains that the majority of failures are head failures, such as split or crushed heads, and are due not to imperfect track conditions, but to defective material in the rail.

The appropriations for the Panama Canal for the year ending June 30th, 1914, amount to $16,265,393, and include the cost of drydocks, wharves, warehouses, a quarantine station, as well as two colliers of 12,000 tons capacity each, to be built in the United States. In addition to the above, $4,870,000 are appropriated for fortifications of the Canal, including $2,635,000 for sea-coast batteries, $173,000 for electric light and power plants, $285,000 for searchlights, $180,000 for filling in the swamp behind the military works on Margarita Island, and $1,000,000 for cannon and equipment and one 16-in. gun and carriage, etc.

WINNIPEG RAINFALL.

By F. Hill Parr, C.E., M.Inst.C.E., M.R.San.Inst.
Engineer to the Rural Municipality of Kildonan.

RAINFALL and the precipitation of snow forms an interesting and essential part of a municipal engineer's study, and it is only by the careful comparison of precipitations extending over years that an appreciative knowledge can be obtained.

The Dominion Government has established meteorological stations in many centres, and from these information is carefully and accurately conveyed by code daily, and by monthly and annual reports.

The attempt to set the following tables before those interested is a plea in the first instance for the further provision of these stations; in the second for the annual distribution of tabulated data, and in the third for the recognized establishment of stations in every municipality. For general information it would be difficult to find a more concise and better form than that in use known as "British Rainfall," edited and published by Dr. H. Mill, of London, England.

Table of Rainfalls, Municipality of Kildonan, 1906-1912, Inclusive. Rainfall up to and Including 0.19 Inch.—Table I.

Average 0.06 per rainfall.

Humboldt assigned rainfall as varying with the latitude, the greatest being at the equator and diminishing towards the poles, in the following ratio: equatorial zones, 96 inches; at the 20th latitude, 80 inches; at latitude 45°, 29 inches; and 17 inches at latitude 60°. Again, this may vary throughout districts in the latitudes, owing to their positions in relation to the sea, large areas of water and the general configuration of the land surfaces.

Average 0.246 inch per rainfall.

As to the cause of rainfall, this does not call for any explanation here and as to evaporation and percolation, also falls without the province of this article; but again, conditions vary under each head to such a degree that for reliable figures for this continent the subjects should be diligently studied.

In some instances in the tables certain subdivisions of rain and snowfall are given, and these occur only after the determination of one of the seasons, and with them has occurred a lowering or raising of temperature.

The precipitation of snow by seasons forms a not uninteresting table, and would be of greater value, were it possible to record the actual period of thaw each spring.

The tables have been prepared with a view to establishing data for the calculation of the run-off from snow and rain. With regard to the latter, it is certainly regretable that automatic rainfall recorders are not more generally in use in the Prairie Provinces. The expense of establishment is possibly the reason of this, but surely municipalities that are contemplating the installation of sewerage

and water systems should not fail to provide the necessary means of obtaining such important information.

In conclusion, the writer wishes to express indebtedness to Mr. H. C. Cox, of St. John's College, Winnipeg, who supplied the records of the rainfalls, etc., from which the tables have been compiled.

WINNIPEG'S MUNICIPAL POWER PLANT.

The waterfalls and works of the Winnipeg civic hydro-electric power and light plant are located at Point du Bois, on the Winnipeg River, seventy-seven miles north-east of the city of Winnipeg. The water fall (naturally 32 feet) is increased by the power development dam to 47 feet. The total available power without storage is 60,000 horse-power, which can be increased to 100,000 horse-power. The present installation is 28,000 horse-power, the full capacity of the present building being 45,000 horse-power. The average flow of water is 25,000 cubic feet per second. The transmission line (owned by the city) is 77 miles long and 100 feet wide, upon which is constructed one line of double towers, with transformer station and distributing stations in Winnipeg. The cost of the plant, including power house, dams, wires, forebay, tailrace, intake, rack piers, for full installation, machinery, transmission line, transformer station and distribution stations is $5,400,000.00. The work of the first year's operation of the plant was entirely satisfactory. The cost of domestic lighting has been reduced seventy per cent., and that of power proportionately, and the plant is already paying its way, the revenue monthly covering the cost of interest, operating expenses, depreciation, advertising and other expenses.

The city of Hamilton is contemplating the purchase of a large gravel pit near Guelph. The gravel contained therein has been found to be well suited for use in civic construction, and if the city acquires it, the understanding is that a stone crusher will be installed and a railway switch run into it for immediate use.

AN UNUSUAL ENGINEERING OPERATION.

The accompanying illustration has been sent in by Mr. E. Bennett, a Toronto contractor, and relates to an incident described in *The Canadian Engineer* September 5th, 1912, in which issue an article appeared relating to the destruction of an arch span at Oakville, Ontario.

Readers are referred to the article. The illustration herewith is descriptive of the method of dynamiting and shows the position and simultaneous explosion by electric spark of the shots placed in the crown and near the haunches of the arch.

AMERICAN ROAD CONGRESS.

Systematizing the purchase of all road materials and equipment through the establishment of purchasing departments, somewhat along the lines followed by great railroad corporations, is strongly advocated by Maj. Henry G. Shirley, Chief Engineer of the Maryland State Roads Commission, in a paper which he will present at the third American Road Congress, which will be in session at Detroit, Mich., during the week of September 29. An intelligent selection of material and equipment, exact knowledge of values and prices and utilization of discounts and credits are among the advantages claimed for a centralized system for the purchase of road materials and equipment.

The construction and maintenance of concrete roads, a type which is attracting attention among road builders, will be explained in a paper by Mr. F. F. Rogers, State Highway Commissioner of Michigan, and the discussion on his paper will be opened by Mr. A. N. Johnson, State Highway Engineer of Illinois. A similar treatment will be given the subject of brick roads by Mr. J. M. McCleary, County Engineer of Cuyahoga County, of which Cleveland is the county seat and which has a large mileage of excellent brick roads, the discussion to be opened by Mr. R. Keith Compton, chairman of the Paving Commission of Baltimore.

Tars, oils and asphalts in connection with the construction and maintenance of roads have been so generally used in the eastern states as to bring out much valuable data. The basic paper on this subject will be presented by Mr. S. D. Foster, Chief Engineer of the Pennsylvania State Highway Department. The discussion will be opened by W. A. McLean, Chief Engineer of the Province of Ontario, Canada.

The lessons learned at the International Road Congress recently held in London will be presented at the big meeting in Detroit by Col. Wm. D. Sohier, chairman of the Massachusetts State Highway Commission.

There will be a host of other papers and addresses which will deal searchingly with every phase of the road subject from the standpoint of the engineer, the financier, the legislator and the road user.

THE BRITISH ROAD BOARD.

THE British Road Board was formed in 1910 for the purpose of aiding the county councils and other local authorities of Great Britain in the construction and maintenance of new roads and the improvement of existing roads. The board consists of four members: Sir Geo. S. Gibb, chairman; the Rt. Hon. Lord Pirrie, the Rt. Hon. Lord St. Davids, and the Rt. Hon. Sir J. H. A. MacDonald. W. Rees Jeffreys is the secretary of the board, and Col. R. E. Crompton is its consulting engineer. In addition it has an advisory engineering committee of six.

The board has published its third annual report, covering its operations for the year ending March 31st, 1913, and including, in nineteen appendices, a mass of statistical data relative to its work, and an explanation of the methods of administering its affairs.

While the report covers the year ending March 31st, 1913, in some cases figures are given up to June 30 of this year. Up to this latter date, the total of the grants and loans made amounted to £1,474,793. This was divided among the different kinds of work undertaken, as shown in the following table:

Improvement of road crusts	£1,210,012
Road widenings and improvement of curves, gradients and corners	120,466
Road diversions	29,395
Reconstruction and improvement of bridges	53,842
New roads and bridges	61,078
Total	£1,474,793

The grants and loans indicated up to June 30, 1913, amounted to £3,435,233, or £1,960,440 more than the grants and loans made. This difference is due to the fact that grants and loans may not be actually paid until some time after they are indicated or allotted, since the arrangements under which grants and loans are made may provide for the payment of half the sum indicated in any particular case at the beginning of the work and the remainder at its completion or in instalments payable at the time the grantees are ready to commence work, when the work is half completed and when the work is finished. In this connection, the method followed by the Road Board in making grants is of interest. As set forth in the report, this is essentially as follows:

Any local highway authority may apply for a grant or loan at any time, and all these applications are considered by the board so far as possible when they are received. In deciding upon the making of a grant or a loan, the Road Board investigates its advisability, taking into account the conditions in the district in question, as revealed by information obtained by conferring with the county councils from time to time in regard to the requirements in each county, and from other sources. According to the usual procedure, a county council when making up its estimate for the ensuing year submits to the Road Board a general statement including a list of the contemplated improvements for which assistance is desired. This statement is not usually treated as a formal application, but is followed by a conference of the Road Board and representatives of the county council. At this, and, if necessary, at subsequent conferences, the question is discussed and the decision arrived at by the Road Board after a consideration of the various requests from all of the counties applying for aid. After the Road Board has selected the improvements upon which it is willing to grant aid and has suggested the amounts to be devoted to the work, the local authorities bring in detailed plans and specifications of the work. The Road Board then submits each case to the treasury for its approval, which is usually prompt. The grants are then indicated by the Road Board.

The annual income of the Road Improvement Fund (calculated without regard to the date of the actual receipt of the sums involved) has steadily increased since the establishment of the board, and during the year 1912-13 amounted to £1,252,970 4s. 10d. The details of the income are shown in one of the accompanying tables.

In regard to the policy of the board in making grants and loans, the following statement is included in the report:

In settling the total amount up to which advances may safely be made at any date the board do not confine themselves to dealing with the balance in hand, representing cash received less commitments. They are prepared to anticipate their income to a certain extent, but in view of the limited experience available in regard to the rate at which commitments will mature, and the probability that as the procedure and operations of the board become better known to highway authorities there will be a constantly increasing acceleration in the maturity of commitments and the expenditure of money on assisted works, they have not thought it advisable to anticipate more than a year's income. They are confirmed in this view by the consideration that in their opinion the amount of road improvement work which is being undertaken by highway authorities (apart from urban street widenings to which, for reasons given in their previous annual reports, the board are not generally disposed to make contributions at the present time, except in special cases) is, generally speaking, as much as can practically be carried out by the staff and with the moneys at the disposal of highway authorities aided by advances from the Road Improvement Fund.

At the present time the board are making grants on the assumption that they can safely indicate a sum of about £1,700,000 in addition to the indications made up to June 30, 1913.

USE OF CEMENT AT COLLIERIES.*

By John Gregory.

CONCRETE by itself is much more capable of withstanding compressive than tensile stresses, the ratio being approximately 10 to 1, and in reinforced concrete the object of the designer is to increase the strength of those parts subject to tension by adding steel of suitable section. The size and disposition of the reinforcement are matters of calculation equiring considerable technical skill, as the various stresses have to be worked out and the several members of a structure proportioned accordingly. For important surface works this is somewhat out of the province of mining engineering, and it will be found an advantage to get designs from engineers or architects who have specialized in concrete work.

Underground Roadways.—With regard to the support of underground roadways, however, other conditions prevail. The crushing effect of the strata in deep mines is an unknown quantity, and as the stresses are chiefly in compression the writer has preferred to put in a thick concrete lining combined with heavy steel girders, rather than a correctly designed thinner lining dependent for its success upon an elaborate system of reinforcement. He is not prepared to justify this from a purely scientific standpoint, but it has the merit of being more easily put in by the ordinary colliery labor, and if the necessity should arise, it lends itself more readily to repair or renewal.

The first application at Sneyd Collieries was in 1908 when, owing to the failure of a brickwork barrel arch, 4 ft. in thickness, it was necessary to reconstruct the insets in a pit 1,860 ft. deep. Steel girders, 12 in. by 6 in. by 56 lbs. per ft., were obtained, bent to a circle having an internal diameter of 14 ft., each ring being composed of three segments, secured at the joints by fishplates and bolts. On the eastern side of the pit, the ground was very bad owing to the roadway intersecting a large fault having a downthrow of 100 yards, and here the girder rings were spaced 18 in., centre to centre. Where the ground was more settled, this distance was increased to 3-ft. centres. Sufficient ground was taken out to allow of at least 18 in. of concrete being put in, measuring from the inside face of the finished arch, and the concrete was well rammed in between and at the back of the girders, making a smooth finished barrel arch of 14 ft. diameter.

The girder rings were taken down the pit in sections and erected in position, a special portable standard being designed for raising the top segments. Temporary laggings laid on the top of the girder rings served to support the roof whilst the concrete was being put in, being removed as the work progressed, and although three parallel lines of rails were in use during the time the work was in progress, no interruption of coal-drawing was occasioned.

When cross-cuts joined the main road, the spacing of the girder rings was increased to allow of smaller rings having an internal diameter of 7 ft. 6 in. or 6 ft., to be inserted, their axis being at right-angles to the main tunnel. In these instances old rails were used to bridge the space between the large girders, resting on the inner flanges. The concrete lining at the junction was properly groined, and when finished had an exceedingly neat appearance.

The results achieved were so satisfactory that it was decided to adopt a similar method of securing a crut, 200 yards long, at a depth of 2,010 ft. This was also driven through the large fault already mentioned, and with the original timber supports the cost of upkeep of the road was very heavy. Girder rings of the same section but 10 ft. internal diameter were put in, the spacing again being dependent on the nature of the ground. Where it was necessary to provide manholes, two rings of 12 ft. diameter were placed eccentrically to the axis of the main tunnel. This work was also commenced in 1908, and so far as appearances go, it will be unnecessary to spend a single penny in maintenance during the life of the colliery.

Since the completion of the above, many of the main roads, airways, and water lodges have been lined in a similar manner. In very few instances have signs of crushing been observed, and in no case has it been necessary to renew the concrete, though this would be a much less expensive operation than renewing brickwork arches. The slight crushing which has taken place has invariably occurred where the roof had fallen to a considerable height, and the space intervening between the top of the concrete arch and the solid ground had been made good with chocks and loose débris, making the crush on the arch unequal. Now this is filled up solid with concrete or brickwork, or if this is not practicable, the concrete lining at the weak spot is considerably strengthened.

Other Colliery Purposes.—Stables and motor houses have been constructed in concrete, and although their initial cost is somewhat high, the saving in upkeep will soon repay for the first charge. In good ground a modified cross-section has been adopted, and the steel formers made from old pit rails bent to a shape resembling a square with rounded corners. The sides are smooth and dust is easily removed, and the entire absence of combustible material commends itself where electrical apparatus is installed.

In one or two instances, girder rings, 12 in. by 6 in. section, embedded in concrete in a similar manner to that described for the roadways, have been used with conspicuous success for pit-shaft repairs. Where the shafts cut the 100 yards fault already mentioned, brickwork lining, 4 ft. 6 in. thick, has been crushed, but where this has been replaced by concrete, no sign of weakness has yet been observed. Many other instances in which the use of concrete is a distinct advantage suggest themselves, and there seems no limit to its useful application. Straight steel girders, with concrete rammed in between, have been used in air-crossings, floors for double landings, foundations for machinery, etc. In several instances, main airways have been lined with concrete without the use of girders, the smooth surface of the finished work reducing the friction of the air and presenting no ledges for the deposit of dust.

On the surface the most important use to which concrete has been applied up to the present is in the construction of a bunker to hold 300 tons of pit dirt, and a gantry carrying a creeper and tram rails for conveying the loaded tubs to a tippler on the top. This work was designed and executed by reinforced-concrete specialists. The cost was approximately equal to that of a steel structure, and the advantages gained are an increased life and the saving of the expense of painting every few years.

Engine-room floors, stillages for oil stores, etc., on the surface have been put in by the colliery staff. For

*Paper read before the North Staffordshire Mining Institute.

work of this class expanded metal makes an excellent reinforcement, and data for the construction of floors suitable for safe working loads of from ½ cwt. to 6 cwts. per superficial foot can be readily obtained.

A further application of concrete, of special value where old shallow mines have been worked, is in the formation of rafts for the foundations of heavy or valuable buildings. For important work these should be properly designed to avoid unnecessary waste of material, but for small jobs the writer has found old rails interlaced with steel guide rods, or even wire ropes, quite successful. The examples given might be multiplied indefinitely.

Selection and Mixing of Materials.—For the benefit of those who might be inclined to adopt reinforced concrete, Mr. Gregory offered some practical hints on the selection and the mixing of the materials:—

Cement.—For all reinforced work, and particularly for underground application, when some considerable time generally elapses between the mixing of the concrete and its being placed in position, a slow-setting cement should be selected. Considerable variation exists in this respect with different makes, and before adopting any particular brand tests should be carefully made. The selected cement should, in addition, comply with the British standard specification as to fineness, specific gravity and tensile strength.

Sand.—This requires equally careful selection. When examined under the microscope the grains should appear sharp and angular. Many sands are mixed with clay or loam, and this is fatal to the making of sound concrete. Washing is sometimes resorted to with a view to eliminating these impurities, but in this district no difficulty is experienced in obtaining suitable qualities locally.

Aggregate.—For underground work the writer strongly advocates broken granite. In the work described two sizes have been used, namely, ½-in. chippings and 1½-in. screened stone. For many purposes on the surface broken bricks or saggars may be advantageously used, but it must be remembered that the sand and cement simply form a matrix or mortar binding the aggregate together, and the greater the strength of the individual fragments of aggregate, the greater the ultimate strength of the concrete as a whole. The aggregate forms the bulk of the finished concrete, and it is useless to get good cement and sand to bind together material which cannot in itself offer considerable resistance to a crushing load.

Gauging.—The correct proportions of the various classes of aggregate sand and cement vary according to the size and shape of the individual fragments. Theoretically, the intersticies or voids in the large stone should just be filled by the smaller stones, and the voids still remaining should be completely filled up by the mortar of sand and cement. In practice a considerably larger proportion of the smaller material must be used, in order to insure a compact concrete, owing to inequalities in mixing and stowing. The voids in the various grades of aggregate are easily determined by filling a box of known capacity level full with the stone to be tested, and adding a measured quantity of water until it is on the point of overflowing. With the aggregate adopted at Sneyd the following proportions by measure of the material give good results:—

1½ in. broken granite	36% or 9 parts
½ in. granite chippings	32% or 8 parts
Sand	20% or 5 parts
Cement	12% or 3 parts

The proportion of the neat cement to aggregate, including sand, is thus 1 to 7⅓. The aggregate, sand and cement are measured out accurately in the proportions stated above and then mixed well dry, after which a measured quantity of water is added and the whole thoroughly mixed wet.

Owing to the finished concrete forming a homogeneous whole without intersticies, the bulk is considerably reduced in mixing, and forms only 60 per cent. of that of the dry material. For making 1 cubic yard of concrete, therefore, the following table gives the quantity of each ingredient based on the proportions already stated:—

	Cu. ft.
1½ in. broken granite	16.2
½ in. granite chippings	14.4
Sand	9.0
Cement	5.4
	45.0

The mixing can be done by turning the material over with spades, but careful supervision is necessary, and it is difficult to ensure that the whole of the ingredients are thoroughly incorporated first in the dry state, and afterwards when the water is added. When much work is likely to be carried out, the writer strongly advises a machine, the cost of which is speedily recouped by the saving in labor, and absolute uniformity in the quality of the cement is secured.

Cost.—The cost of the application of concrete underground is dependent to a great extent on local conditions. The nature of the ground to be excavated and the facalities for the transport of the materials to the site are factors which it is necessary to take into consideration for each individual job. The following table gives the cost of the raw materials for 1 cubic yard of concrete as used at Sneyd Collieries, and will be some guide in working out an estimate:—

Material	Cubic feet	Weight in lbs. per cubic foot	Total weight in lbs.	Price per ton s. d.	Total s. d.
1½ ins. granite	16.2	84	1,360.8	9 6	5 9
½ in. chippings	14.4	84	12,906	7 6	4 0
Sand	9.0	80	720	6 6	2 1
Cement	5.4	95	513	36 0	8 3
Water	—	—	202.6	—	—
Total per cu. yard	—	—	—	—	20 1

The cost of stowing the concrete in position, including fixing the centering, is approximately 3s. per cubic yard, and mixing with the machine about 2d. per cubic yard. If girder rings are used, their cost has to be added, and as an example the cost per lineal yard of a barrel arch, 11 ft. in diameter, with rings spaced 3-ft. centres, is given:—

	£	s.	d.
1 girder ring 19 cwts. at £10	9	19	0
6.55 cubic yards concrete at £1	6	10	10
Stowing cement 6.55 cu. yds. at 3s		19	8
Fixing girder rings		7	6
	£17	8	0

This, of course, excludes the cost of excavation or of mixing the concrete and conveying it underground to the position required. Where the girder rings can be dis-

pensed with, it will be seen that the cost can be enormously reduced, the steel representing more than half of the total expenditure.

It is important that running water does not come in contact with the concrete until it has set, as the cement is liable to be washed out. When this has to be contended with, the general method adopted has been to put in temporary dams and pipe the water across the green concrete.

FUEL IN THE UNITED KINGDOM.

The industrial development of Great Britain is mainly due to the cheapness of fuel, raw material, labor and transport. The coal produced is anthracite and bituminous, and as the deposits to be found in Great Britain are being gradually exhausted, attention is being paid to the use of coal wastes, etc., which were formerly dumped over the tip as worthless. The cost of coal is low at the pit mouth, despite the enormous expenditure involved in the machinery, deep shafts and an increasing labor bill, yet the most inferior of slack and washery-refuse are now being consumed in considerable quantities for the development of cheap power. As one instance of the influence of cheap fuel and power the North-East Coast (England) Power system is referred to by R. O. Wynne-Roberts, M. Inst. C.E., in his report on the Coal and Power Resources of the Province of Saskatchewan. There are seventeen generating stations belonging to this company, of which six are coal-fired stations and the remainder waste heat stations, where steam for generating the electricity is obtained either from exhaust steam that has already done work in blowing, or other engines, or by steam raised by blast furnace gas, or from the waste heat and gas from coke-ovens; the total horse-power connected amounts to nearly 200,000. The engineer in his description of the work pointed out that cheap fuel is of paramount importance, and expressed his opinion that the future of electricity supply lies in the very large stations employing very big units of plants and established at the coal-fields. The above electrical installations have afforded facilities which have attracted several new industries to be located within the area of supply. The same remarks are applicable to the manufacture and distribution of gas, which is being adopted more generally each year.

The next International Geological Congress will be held in Belgium in 1917. "The Agricultural Resources of the World" will then be presented. Many geologists consider that the study of agricultural deposits of the world is the most important branch of geology, and by far the most important branch yet to be investigated. Owing to the fact that large territories of agricultural land have been discovered within the last ten years in Canada, South Africa and Australia, there is as yet no accurate compilation of the agricultural resources of the world. Another reason for the decision to investigate the world's agricultural resources is the attention at present being directed by political economists all over the world to the high cost of living. The geologists believe that if they can collect full details on the grain-growing land resources of the world, the march from the cities to the land will be strengthened and the price of food commodities will be moderated. Another topic that will be discussed in 1917 will be the nitrate, phosphate and soda deposits of the world. As these three chemical compounds form the basis of all fertilizers, the research to be conducted by the scientists will be of great importance to the subject of agriculture. Besides these topics the Belgium Council will be at liberty to consider two others which were suggested by the council. These are the world's copper deposits and petroleum resources.

BITUMINOUS CONCRETE PAVEMENTS.*

By Wm. B. Spencer,
President of the Continental Public Works Company, New York City, N.Y.

Up to the time of the advent of the automobile the question of modern highways was pretty well solved, except in the more highly trafficked streets of our great cities, by the discoveries of John Macadam, and the more recent improvements of the French engineers and the pioneers of this country. But in their system of road building the pioneers did not contemplate heavy vehicles carrying loads of from one thousand to twenty thousand pounds and passing over their prepared roadbed at the rate of from five to fifty miles an hour, sucking up the carefully placed filler or binder, and depositing it over our lawns, our farms and in our houses, permeating the entire atmosphere with a dust which was both objectionable and unhealthy. In response to the immediate cry of protest, engineers at once attempted to solve the puzzling problem. In the West temporary relief was found by taking the crude natural asphaltic or semi-asphaltic oils of California, Texas and Kansas and sprinkling them over the macadam roadways. This generally gave temporary relief from the dust nuisance, but it was found that these oils, which had not gone through the process of refining, contained many substances which were detrimental to the automobile tire. It was also found that they had a decidedly bad effect on the binding materials of the macadam roadways. A well-bound macadam roadway secures its cohesiveness by the hydration of its granular constituents, but when the surface coat is more or less thoroughly sealed by the application of a heavy oil, then the body of the mass is denied the water which prolongs its life, and shortly thereafter the road will commence to ravel.

Some time during the year 1903 an observer in the oil regions of California noted that a flock of sheep, which had been driven back and forth to pasture, over an oil-saturated piece of ground, gradually consolidated this soil to such a degree of hardness that it was not affected by vehicular traffic, and also produced a highway which was cheap and did not require the use of stone, which had always been deemed necessary for the construction of highways. A tamping roller, made as nearly as was mechanically possible to imitate the sheep's foot action on the soil, was designed, and the "Petrolithic" or tamped road was launched. In some sections of California it met with fair success, and is still in limited use in that section of the country.

In the summer of 1907 a road of the same type of construction was laid near New York City, and during the summer and fall season of that year it withstood traffic conditions remarkably well, but during the early winter frost penetrated the road and immediately thereafter a warm rainy period ensued, with the result that the road rapidly disintegrated and became a quagmire. The following spring it was found necessary to entirely remove the prepared roadway and substitute another form of road construction.

The Petrolithic specifications were substantially as follows:—

*Part of a paper read to the American Society of Engineering Contractors, and appearing in the Journal for June.

The earth roadway to be improved shall first be cleared of all vegetable and other foreign materials and shall then be crowned with a road grader, or by hand, to the proper line and grade, filling in all low places with suitable material. It shall then be plowed to a depth of not less than eight inches, after which a disc-harrow shall be run over the surface of the plowed roadway in order that all lumpy material shall be disintegrated. The road shall then be carefully graded to the required cross section, after which there shall be distributed one gallon of hot asphaltic oil to the square yard of pavement. The sheep's foot or tamping roller shall then be used until its teeth refuse to penetrate into the soil for a distance of more than one inch. The material shall then again be lightly harrowed and an application of hot asphaltic oil, at the rate of not more than one-half gallon to the square yard, shall be applied, and the surface shall then be lightly harrowed, after which the tamping roller shall be again used until the teeth refuse to penetrate. The surface shall then be covered with a coating of stone chips or sand and rolled with light circular roller.

Other experiments with the same or allied processes were made in the east during the ensuing year with no better results, and in so far as this type of construction is concerned, it has been virtually abandoned outside of California.

Various states and municipalities then attempted to improve on the water-bound macadam and its filler of stone chips by substituting heavy asphaltic or semi-asphaltic oil, by means of what is termed the penetration or grouting method. The initial process relating to the preparation of the base and first course of stone was substantially the same as in the preparation of the water-bound type of macadam. The second course, generally composed of what is known as inch and a half stone, was then spread upon the base course and rolled with a 10-ton roller to an average thickness of about four inches. An application of asphaltic oil, heated to a temperature of approximately 300° F., was applied, at the rate of one and one-half gallons per square yard, by means of pouring pots or sprinkling wagons and immediately thereafter a coating of stone chips was applied and the surface was then again carefully rolled with a steam roller. Immediately after this rolling another application of hot oil was made at the rate of approximately one-half gallon to the square yard, and another course of stone chips applied, after which the surface was again rolled, and after a short period of time, ranging from 3 to 24 hours, the road was opened to traffic.

The success of this type of pavement is somewhat problematical, and has been abandoned in many places. The States of New York and New Jersey spent many millions of dollars in this type of road construction during the seasons of 1910-1911, but during the season of 1912 the use of this type of construction was almost entirely abandoned. In order to make a success of this type of construction it has been found necessary to have almost ideal climatic conditions. A working temperature of over 55° F. has been found necessary because in a lower temperature the stone becomes so cold that it immediately chills the asphaltum when applied and prevents it from thoroughly penetrating the voids in the mass; an unstaple top surface coat is thus formed with an under strata which is poorly consolidated Traffic soon finds the weak spots in this pavement, with the result that ravelling soon begins and the complete disintegration of the pavement is only a matter of a short time. In order to secure even fair results from penetration work the following conditions are absolutely necessary: An asphaltic oil of approximately 18 Beaume gravity at 77° F. A flash point of not less than 400° F. A fixed carbon total of not more than 6%. A bitumen content of not less than 99%, and a paraffin scale residue of not more than 3%. This material should be heated and applied at a temperature of not less than 300, or more than 350° F. The temperature of the air should not be less than 60° F. The mineral aggregate should be bone dry and the asphaltic oil should be applied to the surface by means of sprinkling appliances containing an exact quantity of the material; templates, or other means of determining the exact quantity of oil to be applied per square yard of roadway should be laid on the prepared road surface, in order that an even distribution of the oil may be secured.

Power sprinkling devices employing compressed air as an atomizer have been used with fair results, but the continued decrease of this method of construction in favor of some method of the mechanical mixing of the cementing medium and the mineral aggregate, is proof evident that at its best the penetration system is only a step in the right direction from the water-bound macadam era to the present era of mixed bituminous surfaces.

Bituminous Macadam.—This type of pavement has been largely adopted for use on main highways and also on the principal streets of some smaller towns. A specification of this type of pavement as prepared by the State Highway Department of Pennsylvania is submitted herewith.

"After completion of the bottom course, telford or macadam, the bituminous macadam course is to be placed thereon. It shall consist of a mixture of bituminous material and good hard stone acceptable to the State Highway Department, trap rock preferred. When trap rock is used the stone shall be of such size as will pass through a two-inch ring and be rejected by a half-inch ring, and shall be entirely free from dust. When limestone is used it shall be of such size as shall pass through a three-inch ring and be rejected by a one-inch ring. When asphalt is used it shall contain not less than 90% bitumen and shall be heated to a temperature of 350 to 400° F. When tar is used it shall be heated to a temperature of 270 to 325° F. The bituminous material shall be mixed with the stone in a mechanical mixer and then spread on the telford foundation to a depth of five inches in the centre for a width of six feet, and to a depth of four inches on the sides, loose measurements, and thoroughly rolled and compacted. One and five-tenths gallons to two gallons of bituminous material per square yard of road surface will be required to make the mixture. The contractor shall, upon the direction of the engineer in charge, heat the stone to a temperature of 250 to 300° F. before mixing the compound. After the above-mentioned course has been thoroughly rolled in place and compacted with a ten-ton roller, to the satisfaction of the engineer or inspector in charge, and the surface swept clean, the surface shall be painted with the neat bituminous material, using five-tenths of a gallon per square yard of road surface, unless otherwise directed by the engineer. Immediately following the flush coat or painting there shall be applied a coating of clean rock screenings, ¼ to ¾ inch in diameter, of the same material as has been used in the four-inch course, to a depth of ½ inch and rolled into the voids in the surface. Should the bituminous binder appear on the surface after rolling, enough additional rock screenings must be applied to take up the surplus material."

This type of construction is one which leaves considerable to be wished for. Personal experience has led me to believe that the grading of the mineral aggregate is not done with sufficient care to give a minimum of voids in the mass, with the result that depressions and ravelling are apt to occur in a period of not more than three years after the pavement is laid.

Bituminous Concrete.—The specifications covering this type of construction are no doubt familiar. In a general way, however, a grading of mineral particles ranging from material which passed a 200-mesh sieve to a maximum amount of from 5% to 11%, to particles which passed in a 2-mesh sieve to a maximum amount of 10%, is used. Where this pavement has been laid with care and by experienced contractors it has met with extreme success, and is being specified in ever-increasing quantities in all parts of the country. During the season of 1912 the City of New York awarded contracts for the construction of over one million five hundred thousand square yards of this type of pavement in the Borough of Queens. The highways on which this pavement is laid are the main arteries of travel leading to and from Greater New York points on Long Island. Over eighty per cent. of this travel consists of pleasure automobiles and heavy auto trucks, and a majority of the remainder being heavy horse-drawn farm wagons. A traffic census taken on the Merrick Road this summer showed an average of over six thousand vehicles a day, with a daily total of approximately ten thousand vehicles passing over it on Saturdays, Sundays and holidays.

The pavements have been down for too short a time yet to be able to judge of their future wearing qualities, but what they have gone through the past season with excellent results is evidence of the fact that they will bear the heavy traffic imposed upon them for many years to come without the necessity of any large amount of repairs. The old roadbed consisted, in the majority of cases, of old macadam, which had been worn down to the base course of stones. This course was lightly scarified and sufficient 1½-inch stone was added to bring the road to the proper cross section and crown, and two inches below the finished grade. A layer of screenings or sand was then applied and worked into the voids by means of hand brooms and puddling with water, and the whole foundation was then thoroughly rolled with a 10-ton macadam roller. The bituminous concrete was then laid and raked by expert rakers and then thoroughly rolled with a 6-ton tandem roller until it had an ultimate thickness of two inches. The pavement was then dusted with a coat of Portland cement to fill any surface pores and was opened to traffic after a period of not less than 12 hours.

In order that the shoulders of the roadway should be protected, a layer of 3 rows of vitrified block were butted in against each side of the roadway and the joints were then poured with an asphaltic filler. In the outlying sections the wings of the roadway were carefully graded and suitable gutters were constructed leading to masonry seeping basins. In sections where storm water sewer systems prevailed the gutters were paved with either cobble or brick and the construction extended from curb to curb.

Among the other forms of modern bituminous pavements may be mentioned those which come either under the patents or control of the Warren Bros. Co., and consist of the well-known Bithulithic pavement, Warrenite and Amesite.

There is also another type of pavement which has recently come into vogue in the Middle West, and is also being used in some parts of the East. It bears the trade name of "Dolarway" pavement. This process consists of first laying a concrete base of suitable thickness of rather a rich mixture and providing suitable expansion joints. Immediately after the laying of the concrete and before the initial set has taken place, the top of the concrete is carefully trowelled, in order to have a uniform finish, and to bring the finer particles to the surface, after which the surface is broomed. Upon this foundation there is spread a layer of hot bitumen at the rate of about ⅓ gallon to the square yard, immediately after which a uniform layer of clean dry sand or stone screenings is spread in a sufficient quantity to cover the asphalt coat and leave a wearing coat not less than ¼ inch in thickness. This pavement is at the present time in its infancy and it is therefore impossible to form an opinion as to its permanent quality. One good feature of this type of pavement, however, is the fact that irrespective of the wear of the surface course there always remains the concrete foundation which can be used either for a new application of this same type of surface treatment, or it can be used for another type of pavement.

Sheet Asphalt.—This type of pavement has probably received more praise and at the same time more criticism than any other form of bituminous pavement, but in the writer's opinion there is no more substantial bituminous pavement laid than modern sheet asphalt pavement. In the early days, and even in more recent times, paving engineers have given too little attention to the details which go to make up a good modern pavement of this type. This lack of attention to details is slowly being eliminated, due greatly to the fact that intelligent bodies of engineers and contractors have been working together to standardize the specifications covering this type of pavement. A set of standard specifications covering the making and laying of sheet asphalt, which is the result of many years' study and labor, has recently been published by the American Society of Municipal Improvement. A digest of these specifications may be of interest:

Refined Asphalts.—The tests provide that all penetrations shall be made at 77° F., and are to be expressed in hundredths of a centimeter with a No. 2 needle acting for five seconds under a total weight of 100 grams. There is no distinction made between the so-called natural or lake asphalts and the oil asphalts; i.e., those derived by distillation from asphaltic oils, it being stated that all asphalts shall be prepared from a natural mineral bitumen, either solid or liquid, or a combination thereof, by suitable and approved methods of refining.

All shipments of refined asphalt shall be uniform in consistency, and shall not vary more than 15 points in penetration at 77° F. Ninety-eight and one-half per cent. of the total bitumen shall be soluble in carbon tetrachloride.

Flux.—The specifications covering the fluxes state in part that they shall be the residue obtained by the distillation of paraffin, asphaltic or semi-asphaltic petroleum, and shall be of such character that they will combine with the asphalt to be used to form an acceptable and approved asphalt cement.

Binder Stone.—The requirements are that the stone shall be clean, hard and free from any particles that have been weathered and are soft. It shall all pass a 1¼-inch screen, and from fifteen to thirty per cent. shall pass a ten-mesh screen. Particular attention is called to the latter requirement. Strict conformation with this phase of the specifications will produce a dense binder which

will have much to do with the ultimate life of the pavement.

Sand.—The careful grading of the sand particles has received more study in recent years, with the result that the modern specifications are as follows:

200 mesh, 0 to 5%				
100 mesh	and retained on	200	mesh,	10-25%
80	" "	100	"	6-20%
50	" "	80	"	15-40%
40	" "	50	"	10-30%
30	" "	40	"	8-25%
20	" "	30	"	5-15%
10	" "	20	"	2-10%
8	" "	10	"	0- 5%

Particular attention is called to the large percentage of particles which must pass the 80-mesh sieve and the small amount which pass a 20, 10 and 8-mesh sieve.

It is unusual to find a sand which can comply with both the fine and the coarse requirements of these specifications. The writer is at present engaged in the laying of a considerable amount of sheet asphalt pavement under these specifications in the city of Norfolk, Va., and it has been found necessary to secure two sands in order to produce a blend which meets the requirements of the specifications. The fine grain sand is secured in North Carolina, and the coarse sand is secured by dredging in the Chesapeake Bay. A blend of three parts of the former to one part of the latter produces a mixture which complies in every respect to the requirements of the standard specifications.

The exact quantities of materials used in making a nine-cubic-foot box of our Norfolk paving mixture are as follows:

Sand	880 lbs.
Carbonate of lime	170 lbs.
Asphalt cement	127 lbs.
	1,177 lbs.

A nine-foot box of this mixture lays approximately 5.28 square yards of finished pavement two inches thick after compression with a steam roller weighing not less than two hundred pounds per inch width of tread.

Asphalt Cement.—The requirements of asphalt cement are that it shall be composed of refined asphalt or asphalt and flux prepared in the proper proportions and melted in such a manner that they shall be blended into a homogeneous mixture complying with the following requirements:

(*a*) It shall be thoroughly homogeneous and shall not be oily to the touch.

(*b*) It shall have a penetration between 40 and 75 at 77° F., depending upon the sand and asphalt used and traffic upon the street on which the pavement is to be laid.

(*c*) It shall not flash below 300° F. when tested in a New York State closed oil tester.

(*d*) When heated in an open tin at a temperature of 325° F. for five hours in a hot air oven, it must not show a loss by volatilization of over 5% and the penetration at 77° F of the residue left after such heating must not be less than one-half of the penetration at 77° F. of the original sample before heating.

(*e*) When the pure bitumen of the asphalt cement is brought to a penetration of 77° F. of 50 and made into a briquette having a cross section of 1 sq. cm. it shall have a ductility of not less than 20 cm. at 77° F., the two ends of the briquette to be pulled apart at the uniform rate of 5 cm. per minute.

When the asphalt cement as used has a penetration greater than 50 at 77° F., an increased ductility of 2 cm. shall be required for every 5 points in penetration above 50 penetration.

Binder and Laying.—The binder mixture shall be heated to a temperature of between 200 and 325° and shall be mixed with from five to eight per cent. bitumen. On reaching the street it shall immediately be dumped on the concrete and at once spread with hot shovels and rakes to the required thickness, after which it shall be thoroughly rolled. No more binder shall be laid at any one time than can be covered by two days' run of the paving plant on surface mixture.

Wearing Surface.—The sand and the asphalt cement shall be heated separately to such a temperature as will give, after mixing, a surface mixture of the proper temperature for the materials employed. The sand when used must be at a temperature of between 250° F. and 375° F. The asphalt cement when used must be at a temperature between 250° F. and 350° F. The filler shall be added to the hot sand in the required proportions, and the two thoroughly mixed. The asphalt cement in the proper portion shall then be added and the mixing continued for at least one minute.

Laying.—The surface mixture shall be brought to the street in wagons at a temperature between 230° F. and 350° F., and shall be covered with canvas covers while in transit. It shall then be dumped on a spot outside of the space on which it is to be spread. It shall then be deposited roughly in place by means of hot shovels, after which it shall be uniformly spread by means of hot iron rakes in such a manner that after having received its final compression by rolling, the finished pavement shall conform to the established grade and have a thickness generally of not less than two inches.

The modern sheet asphalt specifications generally require a binder course from one to one and one-half inches in thickness, and a surface course from one to one and one-half inches to two inches in thickness. I have never been able to discover to my satisfaction why it has been found necessary to have such a thick wearing course, as of 2 inches. It is a well-known fact that generally after a surface course has worn much over one-half to three-quarters of an inch that the remainder of the course disintegrates very rapidly. Would it therefore not be better to reduce the thickness of the surface course to one inch, and increase the quality and thickness of the binder course by having a very dense mixture of sand and stone mixed with the proper percentage of asphalt cement, and of a thickness approximately two inches? A pavement of this type laid under my direction more than three years ago has given very good results, and especially in view of the fact that it was laid on a macadam foundation.

The St. Thomas-Windsor extension of the Hydro-Electric power line has been decided upon to pass through St. Thomas, Ridgetown, Rodney, Dutton, and a number of other points. The route selected will allow easy construction, and will be in proximity to the Michigan Central right-of-way. It will serve the largest area and the most thickly-populated district of any route under consideration. The entire line is 112 miles in length, and the construction of it is being commenced.

SOME PRACTICAL EXAMPLES OF PROVINCIAL LAND SURVEYING

TYPICAL INSTANCES IN THE RE-SURVEY OF OLD LINES, WHERE THE SURVEYOR MUST ARBITRATE — REMARKABLE ACCURACY OF OLD COMPASS LINES, THOUGH LITTLE USED FOR THAT PURPOSE IN PRESENT PRACTICE

By J. A. MACDONALD,
Ottawa, Ont.

NEARLY all of the lands in the older provinces of Canada have been surveyed by the magnetic needle or surveyor's compass; so that all lines, division and otherwise, roads, township lines, etc., are based on the magnetic meridian and not the astronomical or due north and south, east or west. These old lines, said to run north, are not due north, but ten to twenty degrees west of north, and the same proportion of error east and west. This does not matter much, but it would matter a good deal if all those compass-run lines were re-run by the astronomical meridian. It is only a few years ago that the land lines began to be run astronomically. The Dominion Government was the first to begin this innovation in dividing up the lands of the North-West Territories, where all lines are now run astronomically and where lines run with the surveyor's compass are not allowed. In the maritime provinces of Nova Scotia, New Brunswick and Prince Edward Island; in Quebec and old Ontario; all land lines were run by the magnetic meridian and any correction, retracement or resurrey work, in these provinces must be done with the compass. As all transits are provided with a compass the lines may of course be run with the transit. But the transit-compass is usually small, usually sluggish, and therefore not usually reliable; so that the regular surveyor's compass with 4½-inch needle is the proper instrument to use in this work.

Old Compass Surveys Wonderfully Accurate.—It is a matter of wonderment to engineers and surveyors, whose only experience is with the transit, how fairly accurate those old compass lines really are. These veteran surveyors are deserving of the greatest credit for the wonderful accuracy of their lines. No modern surveyor could duplicate such work with the magnetic needle. In fact, the modern surveyor has little respect for the compass as an instrument for running lines and courses. The minute accuracy of the modern transit, and the refinement of the courses, down to 30 seconds, causes men to marvel how correct bearings could possibly be run with the compass, when such refinement as seconds or even minutes are out of the question.

The compass, at best, especially in the hands of inexperienced instrument men, is not considered accurate up to 10 or 15 minutes. In fact, the old traverse tables used for calculating compass bearings, were only given to 15 minutes, that being considered the limit of compass accuracy. With the old compass surveyors, however, the limit of accuracy was by no means confined to 15 minutes or the quarter of a degree. With the sensitive needles and perfect order in which the compass was usually kept, and frequent tests made with a standard meridian, the accuracy was refined to 5 minutes and seldom more than 10 minutes. Old surveyors have told the writer—men who were familiar with the use of the modern transit—that they could, and usually did, run their lines within 5 minutes of the accurate direction given of the course. The state lines of the older states of the Union, and of the older provinces of Canada were run with the compass. The line between Pennsylvania and Maryland, run with the compass, is the marvel of modern surveyors for its wonderful accuracy.

Very Little New Work Now for the Compass.—There is practically no new work done now with the compass. By this I mean new work undertaken by the governments of the several provinces. For instance, in New Ontario all lands are now surveyed astronomically with the transit and the direction of the needle ignored, though the isogenic line is noted for reference. In railway surveys the compass is used throughout unless the country is full of mineral, as a check on the transit bearings. Were it not for the possibility of being able to run lines independent of the compass a good deal of territory could not be surveyed at all. In a large portion of northwestern Ontario the compass is of no use on account of the large amount of mineral in the ground beneath. The writer found, while railway surveying in Northern Ontario, between Winnipeg and Lake Abbitibi, that the compass was of no use as a check on the transit bearings on account of the prevalence of various minerals. The present prevalence of wire fences bounding farm and lot lines is a great stumbling block to using the compass on those lines. The proximity of railway tracks is another. In fact, wire of any form in close proximity to the compass makes its readings negligible.

The professional surveyor in the older provinces of Canada must, therefore, use great discretion in the pursuit of his work.

The Professional Land Surveyor Must be a Diplomat.—Of all professions, not excepting that of the doctor, the land surveyor must be a diplomat. In doing correction work, as resurveys and retracements, for the public, the greatest delicacy must sometimes, if not generally, be used in dealing with the interested parties. For instance, in re-surveying a division line between two owners on either side of the line, the task is a most difficult one to adjust fairly and satisfactory to both parties. All traces probably of the old line have been obliterated by time, fires, etc., the existing lines are far from being in correct position, and this incorrect position of the division line may be long-standing, through one and two generations, it may be. The father recognized these old lines during his life time, possibly aware that the division line was not in the right place. But the son who inherits the property will not stand for the crooked, sidling division line, and gets a surveyor to run the line correctly. Then trouble commences, as the man on the other side of the line, when he sees himself losing slices of his land, attempts to stop the survey.

Here is where the diplomatic ability of the surveyor comes in. If he is not diplomatic at this point, and knows the proper initiative, if he is brusque, obstinate and lacking in the great art of reconciliation and diplomacy, a law suit probably ensues.

It is said that it is the province of a doctor to prevent people from getting sick—at least very sick, and that of a lawyer to prevent law suits, so it is the province of a professional land surveyor, dealing with the public, to prevent litigation.

A Case in Point.—The writer was called on to resurvey a division line. The line had been run many years before, but fires and the clearing of the land from woods obliterated the original monuments. The line in places was very zig-zag, and apparently far out.

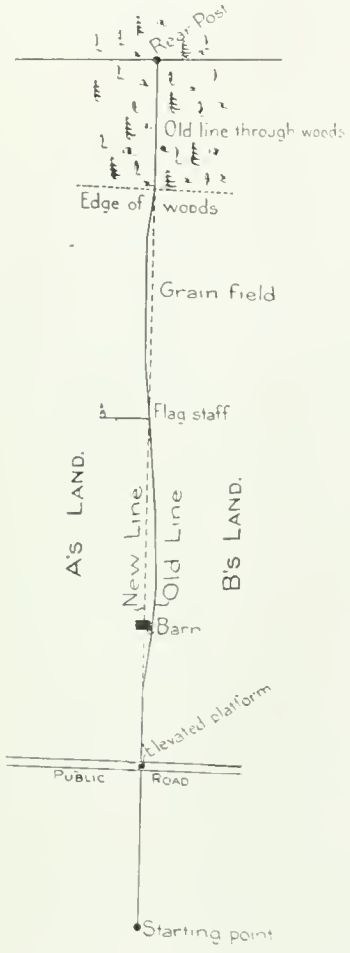

Fig. 1.

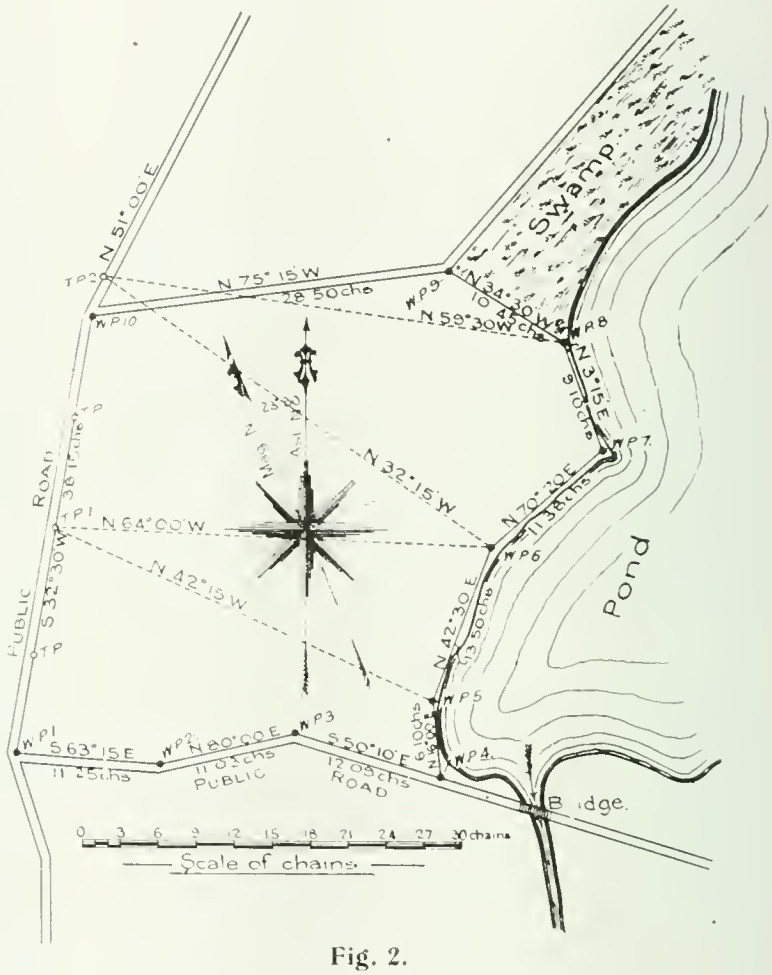

Fig. 2.

Fig. 1 gives a fairly good outline plan of the property. The full lines show the zig-zag position of the division fence line.

In making those correction surveys it is necessary for the surveyor to have a copy of the original deed showing the magnetic direction of the line in the year the land was surveyed. As the magnetic declination changes with years, it becomes a difficult matter to get the correct magnetic course's bearing. In some of the provinces, probably in all of them, there is a standard magnetic meridian laid out by the government under the direction of the Surveyor-General or the Minister of Public Lands, and of this meridian, usually the year the township outlines of the province were surveyed, all compass of magnetic bearings are referred. For example, in one Canadian province the survey of the township outlines was begun in 1776, when the magnetic declination was 15½ degrees. This, then, is the standard magnetic meridian for that province, and all lands transferred and deeded from the government are based or referred to this meridian. Property surveyed, say, 90 years later, in 1866, when the magnetic needle varied since some 8 degrees, would be shown by the surveyor to be this number of degrees west of the meridian, and lands surveyed fifty years before would be 3 to 4½ degrees west, as the case might be, at the particular date of the survey. This simplifies the work of the present-day surveyor, and he knows what he is at, once he determines the magnetic bearing of the original survey which can in most cases be readily obtained, if not of that particular lot, then of a neighboring bound surveyed approximately at the same time.

In Fig. 1 the magnetic bearing of the division line was, in this way, readily obtained, a reliable starting point is also obtainable, and this starting point is of the greatest importance in all surveys, as without a permanent monument to start from it will be almost impossible to make a correct survey.

In the survey in question the old post or starting point was admitted to be in correct position. Here the compass was set with the proper declination of the needle made to reconcile with the original survey, and it was found that the line on the ground, north to the public road, was approximately as it should be. At the road the compass was again set up to get a view of the existing line. The road was on high ground and a good view back and front could be taken. From the back sight and from the reading of the needle, the line for a portion north

of the road was also fairly accurately in correct line, but a few chains farther north the line zig-zagged most outrageously, and looking through the compass sights it was found that the barn of one of the property owners was directly in the line. Here was a "contretemps." The line to the rear from starting point might not be right, and, again, it very possibly was. The barn prevented seeing how the line fared farther on, and without having to offset the line at the barn, and the fact that the line at the road was on the highest ground, it was decided to erect a scaffolding or elevated view-point. This was constructed and the transit (not the compass here) was set up after. Back-sights being taken, it was an easy matter to see how the old line proceeded towards the north. It was found, after zig-zagging on B's property it deflected into A's. At about three-fourths of the distance the line went into thick woods. It was thought, and rightly so, that here the old line would be found; a flag-staff was therefore set at the edge of the wood, and the reading of the needle determined it was found that the original line came out as expected. Where the line of sight crossed the old line, as shown in Fig. 1, a fence pole, about 15 feet long with a small flag fastened to its top, was set up in exact range with the correct line of sight entering the wood. Pickets were set, and the line run straight, sometimes on one side of the old line fence and sometimes on the other, until the wood was reached, when it was found approximately directly in continuation, and followed to the front where old bearings were easily discernible.

The owner who found he was losing a big slice of his land and one-half of his barn was finally consoled by his gain of ground farther ahead and permitted the line to proceed. By the plan it will be seen that the true line went into the other man's grain field, taking off quite a slice of ground. He developed the idea that he would lose in this way all along the line farther on, but when the woods were reached, approximately striking the old line, and were proceeding along it, he was satisfied the new line was correct. Had it not been made plain to the man who lost part of his barn that he would gain farther on, he certainly would not allow the line to be run, and, as he had been 21 years in peaceable possession of the property under fence, he could hold the land in any law court, and have the old line remain as the true line. This is an example of a case where the surveyor must use great delicacy and discretion.

Another Case in Point.—Here an enclosed lot was to be surveyed by compass bearings, as done originally, the various bearings and distances obtained and a correct area of the property determined.

As will be seen in Fig. 2, this land has many sides, and affords some difficulties in the conducting of the survey. There were no division lines, however, which made the survey a less delicate matter, starting at the southwest corner of the lot, marked (1) along the public highway; the course by the compass is S. 63° 15′ E., and a distance of 11.25 chains to station (2). From station (2) the course is N. 80° 00′ E., distance to (3) 11.03 chains. From (3) to (4) the course is S. 50° 10′ E., distance 12.09 chains, at (4) a pond is reached. Here some offsets have to be taken to the banks of the pond, to arrive at the area of the land to the east of station (4). From station (4), the course is N. 16° 00′ E., distance 6.10 chains, and so on. From (4) to (9) the lines skirt the banks of the pond or lake. Offsets are taken to its banks, where necessary, in order to be able to plot the ground correctly, a row of telegraph posts are shown along the public road and marked on the plan T.P. Two of these posts are used for intersecting, in order to determine the degree of correctness of the courses and chainages of distances between monuments. These are a necessary check to the survey where the bounds are deeply angled. At station (5) the compass was sighted to T.P. (1), the course being N. 42° 15′ W.; at station (6) the course sighted to the same T.P. was N. 64° 00′ W. At this station an intersection was further taken to another telegraph post, marked T.P. (2) on the plan. Here the course was N. 32° 15′ W. Proceeding to (8) another intersection was taken to T.P. (2), the course being N. 59° 30′ W.

At station (8) we come to the edge of a marsh and to the delimitation of the pond. At (9) we strike a public highway, one of the bounds of the lot, the course from here to (10) being N. 75° 15′ W., and distance, 28.50 chains. At (10) is the main public roadway or street leading out of the city. This road runs N. 57° 00′ E., but turns at station (10) and runs S. 32° 30′ W. to station (1).

In calculating the area of this lot, resort is best made to Double Meridonal Distances, where there are so many courses and angles, as in this lot, this is the only proper method of calculation, and ensures the accuracy of the survey. As to the manner of computing by this method, the reader can refer to any book on surveying.

A lot of this kind and shape, plotted on a fairly large scale, say, 5 or 10 chains to an inch, can easily be calculated for area by means of triangles, the area of each being obtained by multiplying the length of the base by half the altitude.

Points About Plans to Remember.—All the bearings of a plan must be referred to a single meridian. It matters not whether the meridian is astronomical or magnetic. In nearly all of the land divisions of the older provinces the meridian is magnetic. The angle of any two lines may be given by the difference in their bearings.

The date of a survey is the date on which measurement was completed on the ground. The dates of commencement and ending of the survey which are entered on the title page of the field notes should include all traverse or other surveys within the field book.

The surveyor must not lose sight of the fact that the main object of his plan is to identify the boundaries of the parcels laid out; the plan must not be obscured by irrelevant details. Only the main topographical features are to be represented, and in so far only as they may assist in locating the boundaries. Traverse lines of rivers or lakes, generally are of doubtful utility; they are not boundaries, and as the feature which they define is liable to change, any measurements required may, if the transverse has been accurately plotted, be scaled off the plan with sufficient accuracy. Plans must be plotted carefully and accurately, and must be fair specimens of draughtsmanship.

The title of the plan of a group lot must state the number of the lot, the number of the group, a concise designation of the locality, the district, province or territory, the name of the surveyor, the date of survey and the scale. The designation of the locality must be that one which is in general use among the public in referring to the place.

The plan of a town site must show the whole of the section or lot in which the site is situated, the connections with the corners, and every section, quarter section or lot line passing through or bounding the site. It must exhibit the bearings and lengths of all boundary lines, the posts, the numbers of the blocks, town lots, avenues and

streets, the width and depth of the town lots, the width of the streets and avenues, and the houses and improvements. Only the essential topographical features are indicated.

The title of the plan of a town site must state the name of the town site, the number of the section, or lot in which the town site is situated, the province, district, or territory, the name of the surveyor, the date of survey and the scale.

Plans of highways must show the bearings and lengths of the courses, the monuments, their description, and the bearings and lengths thereto, the main topographical features and the area of the highway, computed to the nearest hundredth of an acre, in every separate parcel crossed by it.

Monuments.—In private or custom surveying wooden posts are used. In Dominion land surveys no wooden posts are now used, excepting in deep swamps. The corner posts of a survey are usually bigger and deeper in the ground than posts used elsewhere.

A wooden post for a corner of farm or settlement lot is 36 inches in length, to be one-half in the ground. It is squared 12 inches from the top, and the faces are about 3 inches wide. The top is bevelled to shed rain. Such a post, when perpetuated by a mound in the northwest, is not placed in the centre of the mound, but in the same position that an iron post would occupy. Mounds and pits are seldom used in provincial work of a correction or jobbing nature. In new government work I believe they are used by some of the provinces.

In the Dominion lands surveys pits and mounds are used throughout, as corner monuments, and also witness monuments, and a square-topped post is only used for settlement lots, group lots, etc. Stone mounds are also employed, whenever stones can be readily procured, and make good monuments for any kind of survey work. These two classes represent the style of boundary monuments largely used by Dominion land surveyors, in work in the western provinces.

MANITOBA'S FOREST WEALTH.

Manitoba has not been looked on as a forest country, but it has always had a considerable area of forest, and, since the boundaries have recently been extended, a large territory has been added which is almost entirely forest land. The forest flora of this province is varied. At the south-eastern corner the red pine of Ontario intrudes, intermingled with spruce, jackpine, tamarack, birch and poplar. Along the valley of the Red and Assiniboine Rivers was a mixed forest of elm, ash, oak, basswood, and ash-leaved maple, where trees were found ranging to 24 inches in diameter. Rising like islands from the agricultural plains, tracts like the Turtle, Riding, Duck and Porcupine Mountains, bore forests of oak, ash and poplar in the Turtle Mountains, and of spruce, jackpine, oak, elm, ash, poplar and ash-leaved maple in the others. The character of the virgin forest may be seen from the following extract from a report of explorations made by Professor Hind on the 8th November, 1858: "I beg to subjoin the circumference, five feet from the ground, of a few trees within 50 yards of our camp on the Riding Mountain: Aspen, 4 ft. 6 ins.: 4 ft. 6 ins.; 4 ft. 1 in.; 5 ft.: white spruce, 7 ft. 3 ins.; 5 ft. 6 ins.; 6 ft. 6 ins.; 6 ft.; birch, 3 ft. 6 ins.; 3 ft.; poplar, 4 ft. 9 ins.; 4 ft. 6 ins. These trees represent, as far as observations permitted, the general character of the forest on the summit plateau of the Riding Mountain."

OXY-ACETYLENE TORCH.

Some tests have been undertaken recently to determine the mechanism of cutting the practical consumption of oxygen and the effect of variations in the different heating flames produced by the oxy-acetylene blowpipe when cutting metal. The metal on which the researches were carried out was a sheet of Martin boiler-plate of a thickness of 10 mm. and a sheet of Martin extra hard steel from 28 to 30 mm. thick. This latter was similar to that used for locomotive girders. It was found that, contrary to the general impression, the act of cutting did not consist of a simple combustion of the iron. In fact, with small or medium thicknesses only a small percentage of the metal removed by the influence of the jet of oxygen was actually burned. It was also found that a heating flame could be too powerful, and so retard the cutting and give an irregular surface. With equal cutting surfaces it was also found that less oxygen was consumed by those blowpipes with a central jet than by those which had separate burners.

It is interesting to note that particular attention is being given in Germany to cutting and welding metals by the oxy-acetylene flame, and, according to an authority, an advanced course in the subject is being given to the students in one largest technical industrial schools in the country. Writing in "Indian Engineering," he points out that the method of application to the various trades is taught, including boilermaking, the work of the blacksmiths, copper smiths, machinists, shipbuilders, pipe-workers, electricians, aluminium-workers, etc. The method is also taught in twenty-one other technical schools, and at Nuremberg a special school is being built to be devoted exclusively to practical and theoretical teaching in this branch. Already oxy-acetylene cutting has begun to displace cutting by tools to a large extent. One direction in which a revolution is being effected is in piping. Instead of having short lengths with screwed joints, which necessitated a certain minimum thickness of m al to allow for the screw threads, the method now being commonly adopted is to use thin plates of steel or iron run through rolling machines to the required diameter and then butt-welded by the oxy-acetylene flame in an automatic machine. Jointless pipes of any length are thus obtained at less cost than formerly, the work proceeding on the spot where the pipes are being used, exactly according to requirements. There is a successful example of a repair to a large cast-iron cylinder which cracked and would have taken a month to re-cast. To prevent the chances of the cylinder developing cracks near the joint, owing to unequal contraction when cooling, it was covered with asbestos on the outside, while a wood fire was kindled inside, which maintained it at a dull red heat while the oxy-acetylene flame was being applied. After completion of the weld the cylinder was covered with insulation and allowed to cool very slowly. The insulation was removed after two days, when the joint was found to be perfect, without the trace of a shrinkage crack. The convenience of repairing by this method the machinery and boilers of ships at sea has only to be mentioned to be appreciated. It can also be realized how great is the saving in time in repairing and putting on the road again locomotives which otherwise might lie for weeks in the shops.

LARGEST DRYDOCK.

The drydock which is to be built at Quebec for the Dominion Government by a Montreal firm will, when completed, be the largest structure of its kind in the world. It is to be 1,150 ft. long and 137 ft. wide, or 100 ft. longer and 17 ft. wider than the Gladstone Dock, which was opened by King George at Liverpool.

POINTS IN CHOOSING A PAVEMENT.

The information which *The Canadian Engineer* has accumulated, respecting the various types of pavements that have been laid in Canadian cities, forms the basis of an article appearing in another part of this issue. The data show a marked tendency toward greater uniformity in the use of pavements for special grades of traffic, and they also show that the question of traffic has been receiving more attention and scientific investigation during the past several years than had hitherto been given it, in the selection of pavements.

The opinions which our city engineers have expressed are of great value in that they are based upon constant personal observation. Where these opinions differ materially from the general conclusions at which highway officials in other countries, and even in other cities of our own country, have arrived are instances which are sources for information of particular value, and which bear out well the old-established belief in experience as the best teacher, though in many cases the most expensive.

That these general conclusions respecting paving practice at home and abroad are subject to modification for any city's particular requirements, does not entirely explain the wide diversity of opinion which still exists throughout the country concerning the pavements that are being used. Although Canada's expansive territory is subject to a considerable range of climatic conditions; to a varying quality in materials, and to a changing and varied collection of vehicular traffic, these factors are not sufficient in themselves to prevent the crystallation and adoption of a more uniform and a more scientific pavement selection than the actual results indicate from practice in the past.

Not that absolute uniformity is desired. *The Canadian Engineer* is not an advocate of hard-and-fast rules in the matter of street paving. Newer methods and materials are being continually introduced, and the trying-out process is slow. But there are many pavements that are well-established and do not belong to the novice class, and the evidence that among them there are pavements that have not been properly chosen in some cases points to towns and smaller cities the wisdom of careful selection. The durability of a pavement has one unredeeming feature, in that it does not furnish an early opportunity for the laying of a more appropriate pavement if a desire for such may develop.

Other characteristics besides durability enter most paving projects. Quietness is desired in residence sections, and on streets lined with office buildings. Sanitariness is desirable on all streets, and the street cleaning department of a city should be shown consideration where possible in the selection of pavements. The quality of unslipperiness is often at variance with the nature of the surface which assures other desired characteristics. Especially in cases of intersections busy with light and speedy traffic, and on ungraded streets, slipperiness is a most undesirable feature. Qualities such as the radiation of heat, reflection of light, emission of unpleasant odors and other factors which concern the pedestrian and the adjoining residents, are also worthy of some consideration.

Further, some pavements, though quite satisfactory when new, may be subject to a wear of such a nature as to render them wholly undesirable, long before they are in such an advanced state of wear as to warrant their being torn up and replaced.

These and other factors influence the choice of a pavement, some lightly, some considerably, depending

on local conditions; and, while one good quality may be obtained at times only at the expense of another, the search for the ideal pavement requires a judicious consideration of them all. The proper time to think of these items is before the pavement has been laid. There will be fewer discrepancies to overlook afterwards, as a result.

STEEL FOR CANADIAN SHIPBUILDING.

The old saw about the ill wind is given another chance in the case of the new Government regulation respecting materials that go into the making of Canadian vessels. The shipbuilding industry receives its share of the good in the clause which states that all vessels built for the Dominion Government must be built in Canada. The steel industry of Canada also should receive a healthful incentive from the fact that all material for the construction of these vessels must henceforth be British product, thus putting an end to the use of steel from the United States for this purpose. Whatever material Canada is not at present able to supply, for a yearly output, may be of such magnitude as to act as a last straw in the breaking down of indecision toward the establishment or the extension of other industries.

But the shipbuilding industry is not jubilant over the necessity of having to look in another direction, than has been the custom, for steel plate. There are items of cost and speed in getting actual construction under way, that are somewhat handicapped by the new rule. The length of time necessary for the delivery from England, of steel and other materials which Canada may not yet be in a position to supply, is going to hold up the fulfilling of contracts. Concerning cost, Canada has been purchasing United States steel for her shipbuilding at a better rate than it is claimed she can get it from Great Britain, the quality being practically the same. Or, she might buy from Belgium at a lower figure than that obtainable in either of the other sources of supply.

So that the Canadian shipbuilding industry is affected by the new regulation to the extent of an increased cost in the materials of construction, and of a longer period necessary for the completion of a vessel.

A CENTRALIZED ROAD BOARD ADVOCATED FOR CANADA.

Returning to Canada, after a study of the evidences of road engineering, as displayed in Great Britain and on the Continent, Mr. A. T. Laing, lecturer in highway engineering, University of Toronto, pronounces as the vital point in Canada's road situation to-day, the lack of organization.

"It is hopeless to expect a satisfactory treatment of the question so long as each municipality continues an independent policy of experimentation with one pet scheme or another at the caprice of a council. What is needed more than anything else at the present time is centralized authority, which, of course, must be accomplished by legislation. The establishment of a board modeled after the British Road Board and modified to meet the conditions here would greatly aid the movement and place it on a substantial basis."

The suggestion is not new to readers of *The Canadian Engineer*, and it is regrettable that engineers, who have a better knowledge than anyone else of the necessity of a comprehensive Dominion-wide road policy on a sound financial basis, do not bring the idea into more prominent publicity, now that the road problem is being so widely discussed in some of the provinces.

Of course, conditions in the two countries are vastly different, and Great Britain with her densely inhabited areas and her comparatively short roads is not a model for Canada to copy. But the principle is the same, and should work out as well in Canada as it has done in England.

BIG PAVING FIRM TO BE WOUND UP?

Application was made last week at Osgoode Hall, Toronto, to wind up the Canadian Mineral Rubber Company, Limited. J. S. Lovell, who was the petitioner, is a creditor for $2,500. It was suggested that this year's business will increase the company's liability by $200,000.

The company was incorporated in 1909, under Canadian laws. It owns a Gilsonite property near Price, Utah; a bituminous limestone property near Tucker, Utah, and also the entire $500,000 capital stock and $500,000 bonds of the American Asphaltum and Rubber Company, of Chicago.

The company manufactures "Pioneer" mineral rubber asphalt, insulating and waterproofing compounds, pipe coatings, paints, etc. The registered office in Canada is in Toronto, but the Toronto office is very small compared with the large staff at the Chicago headquarters of the American Asphaltum and Rubber Company, which handles a large volume of business throughout the United States.

The officers are: D. B. Hanna, Toronto, president; A. J. Mitchell, Toronto, secretary. The directors are the foregoing and Sir H. M. Pellatt and A. D. Davidson, Toronto; H. Sutherland, Winnipeg; J. M. Greata, J. J. Hill and D. Northall-Laurie, Chicago.

The outstanding capital stock of the company is $200,000 preferred and $800,000 common. The bonded debt is $825,000, most of which, it is understood, was issued in England, with the British Empire Trust Company, Limited, of London, as trustee.

It is generally thought that the application for winding up the company is probably the direct result of the suit against the American Asphaltum and Rubber Company, which was won recently in the Illinois courts by a competing company, the Standard Asphalt and Rubber Company, of Chicago. The latter company, which makes practically the same products as are made by the American Asphaltum and Rubber Company, claims to own the basic patents covering the methods of manufacture of many of the American Asphaltum and Rubber Company's products, and their contention was apparently upheld by the courts.

This suit and the subsequent application for the winding up of the Canadian Mineral Rubber Company are of immense importance to paving interests, both in Canada and the United States, because the Standard Asphalt and Rubber Company claim that their patents are basic patents covering every commercial method now known for producing asphalt products.

Toronto has 42.76 miles of macadam roads; Winnipeg follows with 33.75 miles.

The Canadian Pacific Railway Company's tunnel under the Selkirk Mountains is regarded as one of the most important enterprises which has ever been undertaken in the Canadian west. It will be five miles long, and will be built for a double track. The time prescribed for the execution of the works is forty-two months

THE EXTENT AND WEAR OF PAVEMENTS IN CANADIAN CITIES.

CLASSIFICATION OF DATA AND OPINIONS FROM CITY ENGINEERS ON THE VARIOUS TYPES IN EXTENSIVE USE AND THEIR GENERAL SUITABILITY FOR DIFFERENT KINDS OF TRAFFIC — STATISTICS COMPILED BY *THE CANADIAN ENGINEER*

IT is very difficult to fix, with any degree of accuracy, a definite period for the life of a pavement or a definite conclusion as to its serviceability, especially as conditions vary so greatly in different cities and on different streets of a city. No two highway engineers may be expected to agree in their estimates concerning the value of different pavements for this reason. Considering, for instance, the question of durability, although there are many streets on which an ordinary pavement might be considered to be efficient for fifteen or twenty years, or even longer, there are many instances where the same pavement has been carefully laid and has not exceeded ten years in life-time. Again, a stone pavement may withstand heavy traffic for fifteen years, while, under a lighter traffic, and provided it is not opened too frequently, it should last thirty or forty years, if well laid. Such a great deal depends upon the nature of the traffic to which a pavement is to be subjected, that the problem of pavement selection is mainly one of acquiring a composite knowledge of the many present and future conditions to influence its wear. An investigation of traffic is manifestly an important preliminary upon which the success of a proposed pavement depends.

The Canadian Engineer has set about to ascertain an analysis of the pavement situation in Canada—the service which the more extensively laid pavements have given, and the opinions of the engineers as to their suitability for the traffic over them.

The information contained in this article shows conclusively that while the paving of city streets has not entirely passed the experimental stage, there is a marked tendency toward uniformity of opinion among city engineers in the matter of selection. (The pavements that have been laid during the past several seasons, especially, bear this out.) And, where their opinions are shown to differ from the generally adopted conclusions respecting certain pavements, it is to be remembered that many of these types in Canada have served but a short portion of their lifetime, and also that every city has its own peculiar conditions of traffic.

The observations contained herein tend to show that the most suitable pavement has not always been the one selected; and that in many cases, the selection rather than the pavement, is within the range of criticism. Thus, while it is necessary for those who have paving to do to acquaint themselves with the characteristics of the different materials, as they may do by observation, and from the volumes that have been written about them, it is also necessary to study carefully the trend of local civic expansion and traffic.

It is not to be expected, therefore, that the city or town engineer who is in a quandry as to the best pavement to lay on his next street will find solution in the opinions expressed herein; but, the choices which other engineers have made, and the manner in which their pavements are answering, will go a long way toward a satisfactory selection, after he has equipped himself with a well-defined knowledge of his requirements.

From Table I. an idea may be obtained of the extent of Canadian pavements. A grand total is not indicated as a few cities are not represented, while some have included the present season's development and others have not. Mileages of macadam and gravel roads, and of some of the lightly used pavements have also been omitted from this analysis, in order that the more largely used pavements might be more simply described.

Table II. comprises the deductions from present opinions of city engineers in the matter of comparative suitability for different traffic conditions. Here, again, one must bear in mind that these opinions are derived from experience with whatever pavements were first laid, and may not, therefore, conform entirely to what the engineer might advise had he the laying of the pavements to do again.

Opinions as to the nature of wear of pavements and its effect upon the general condition of streets are summarized in Table III. As each type has been used in various grades of traffic in different cities, as indicated in Table II., the conclusions respecting wear are also varied. Where, in one city, a pavement wears evenly, and in another develops holes, the assumption that the nature of the traffic is different is borne out by the data submitted, and in every instance the table expresses the nature of deterioration under the traffic to which it has been more widely subjected, rather than under the traffic for which it might be termed the ideal pavement.

The question of durability of any individual type is far from being satisfactorily answered in the approximate comparison given in Table IV. Traffic does not lend itself to strict classification, nor does it confine itself to the streets best suited for it. As the life of a pavement advances residential streets may become business streets or may develop into channels of dense traffic between business sections. Again, "small" repairs may be occasioned from foreign causes, while the stage where "complete reconstruction" is necessary frequently depends upon the number of times the pavement has been torn up for the laying of mains, etc. At any rate, engineers are not of one mind in the matter of durability of the various pavements in use, nor are the methods and materials of construction so uniform throughout the Dominion that all pavements enter the test for longevity on an equal basis.

Opinions Respecting Pavements in Use.

Asphalt Block.—The earliest report of this pavement being laid in Canada dates 1904. It is generally conceded to be a good pavement for residence streets, and for light traffic streets without car tracks, although several western cities report its favored use for heavy traffic, it is not so recommended by eastern city engineers. It

is a too recently accepted material for authoritative opinions as to durability. It has not always worn well wherever laid, having developed a tendency toward holes and cobbling, and there are instances where disintegration of the lower part of the block has caused trouble. It is likely to endure ten years of service without extensive repair, a few engineers making a more conservative estimate. Many cities mention cost as a prohibitive feature against more general use. When the block commences to wear at the edges, and the surface becomes roughened, it is hard to keep clean.

Asphaltic Concrete.—This is one of the youngest of the pavement family and engineers do not commit themselves as to its wearing qualities. We find no record of asphaltic concrete having been laid in Canada prior to 1909. It is suitable for light to heavy traffic with a tendency to wear into holes. Mr. A. F. Macallum, city engineer of Hamilton, reports its use on grades of from 3% to 7%—too steep for the use of sheet asphalt. On the steepest grades transverse grooves were cut across the pavement every nine inches to eliminate undue slipping in unfavorable weather.

Bitulithic.—This pavement dates from 1902 in Canada, in which year it was laid in London, where it has proved satisfactory, although Mr. W. N. Asphlant, the city engineer, recommends a concrete base for the best results with it. Chatham has had it in use for ten years and reports an even wear with a tendency to holes. Bitulithic is not so liable to markings in hot weather, as asphaltic concrete. Mr. W. A. Adams, assistant city engineer, Lethbridge, endorses the advantages of using a stretcher on streets with car tracks, both inside and outside the rails. Concrete with wire mesh reinforcement has been satisfactorily used for this purpose. Bitulithic appears to answer for all ordinary traffic. It has the advantage of being comparatively noiseless and easily cleaned, although a squeegee coat, frequently applied, makes cleaning a little difficult, and requires the pavement to have a slightly higher crown.

Fifteen years is claimed to be its approximate lifetime before extensive repairs are necessary, although several place this limit at ten years, and in each of these latter cases the pavement has already been down for nine years.

Brick.—Toronto laid brick pavement in 1895, and Chatham in 1896. "Good under all conditions," including steep grades, heaviest traffic and streets with car lines, expresses its efficiency in so far as durability is concerned. Its tendency to edge-wear produces cobbles and holes. On streets with car tracks it will last eight years or more before any repairs are necessary, if carefully laid. On streets with heavy traffic and without car lines this period is extended to fifteen years, while twenty-five years is a conservative estimate for light residential traffic. But no engineer recommends its use for quiet streets.

Mr. L. W. Rundlett, of Moose Jaw, reports laying this summer a vitrified brick pavement in a subway under a railway track. The brick is laid on five inches of concrete, with a sand cushion and grouted with a 1 to 1 Portland cement grout. He regards it as an exceedingly satisfactory pavement for this location.

Brick worn to any extent is not easy to keep clean when revolving brooms are used, but cleans thoroughly if flushing is resorted to.

Sheet Asphalt.—In 1887 Toronto laid its first sheet asphalt and its 157.03 miles now in use indicate that it has been found generally satisfactory. Approximately 350 miles of it are now in use in Canadian cities. It appears to withstand all kinds of traffic well, wearing fairly evenly, with a tendency toward ruts and holes under heavy traffic. It is generally conceded to be a slippery pavement in wet and frosty weather, and requires frequent cleaning for best service. Mr. Arch. Currie, city engineer, Ottawa, states that for his city's requirements this pavement, properly constructed, is the best that can be used. Several cities report a little cracking, not serious, in their asphalt pavements.

No repairs are necessary during the first four or five years. If good sand is used in its construction sheet asphalt will last from ten years under fairly heavy traffic, to 16 or 20 years on residential streets, before reconstruction is necessary.

There is such a tendency to tear up streets for the installation of sewer mains, water and gas services, etc., with an uneven and unsightly patching as a result that quite a number make mention of it in commenting upon the durability of this pavement.

Wood Block.—This type of pavement is considered satisfactory on both residential and business streets. It it well adapted for the heaviest kind of traffic, and has the advantage of being comparatively noiseless. Its tendency, however, toward slipperiness in wet and frosty weather is quite marked.

Untreated wood blocks were laid in Toronto as early as the seventies. St. John, N.B., reports their use since 1880, and Winnipeg had wood block pavements in 1885. Untreated blocks decay rapidly and require replacement after four or six years of wear. Some cities have run traffic of all kinds over them for a slightly longer period, but on the other hand, several report the necessity of repairs after three years of use. Walkerville, Ont., used cedar block very extensively some years ago, but found them to last only five or six years before extensive repairs were necessary, in spite of careful attention to little defects, and of the fact that they were laid on concrete base.

Creosoted wood block pavement goes back about ten years only, in America, with native woods. Some pavements have thrived in New York and Boston for that length of time, and upon them there have been no repairs to date. Treated wood block has not been in use sufficiently long in Canada, however, for engineers to acquire an opinion of its durability. Several hazard a suggestion of fifteen years under heavy traffic, and twenty years under ordinary wear before any extensive repairs are necessary.

Most of Moose Jaw's pavement is creosoted wood block, three inches in depth and laid on a sand cushion. They receive a 16-pound per cubic foot treatment. They have answered well up to the present, except where water and frost has got beneath them. This occurs particularly along the street car tracks, but Mr. Rundlett advises laying the blocks in a cement grout to obviate this difficulty.

The more scientific methods of laying wood block pavement is bringing it into favor for Canadian city streets. Vancouver, Saskatoon, and other western cities appear to be giving this type of pavement a good deal of attention and preference. The Forestry Branch of the Department of the Interior recently issued a bulletin containing the following:—

"Best results are obtained from rectangular-shaped blocks cut from Southern or Norway pine which are thoroughly seasoned and creosoted. This latter process not only lengthens the life of the wood but reduces its absorptive capacity for water, thus preventing the weakening of the wood-fibres and reducing its tendency to buckle. The most approved method of laying this pavement used in London, New York and other large cities, is to first make a concrete foundation four or six inches thick on which is laid a thin layer of sand, or, better still, of moist Portland cement, into which the blocks are closely set.

"The blocks are from five to nine inches in depth and must be free from defects. Care must be taken to place them with the grain perpendicular to the road-bed. If laid with the long edges at right angles to the curb the joints are apt to become worn by the calks on the horses' shoes, so, to prevent this and to best provide for possible expansion, the paving is laid at an angle of about sixty-seven degrees with the curb. The joints are usually filled with ground cement and the surface of the paving is then covered with a thin dressing of coarse sand, which beds into the pores of the blocks and roughens them.

"Such a pavement has the smoothness of asphalt and will last almost without repair for fifteen years under

Comparative Value of Different Pavements.

Pavement.	Per-centage.	Granite.	Sand-stone.	Asphalt (sheet).	Asphalt (block).	Brick.	Macadam.	Creosoted wood.
Cheapness (first cost)	14	4.0	4.0	6.5	6.5	7.0	14.0	4.5
Durability	20	20.0	17.5	10.0	14.0	12.5	6.0	14.0
Ease of maintenance	10	9.5	10.0	7.5	8.0	8.5	4.5	9.5
Ease of cleaning	14	10.0	11.0	14.0	14.0	12.5	6.0	14.0
Low traction resistance	14	8.5	9.5	14.0	13.5	12.5	8.0	14.0
Freedom from slipperiness (average of conditions)	7	5.5	7.0	3.5	4.5	5.5	6.5	4.0
(A) Favorableness to travel	4	2.5	3.5	4.0	3.5	3.0	3.0	3.5
(B) Acceptability	4	2.0	2.5	3.5	3.5	2.5	2.5	4.0
Sanitary quality	13	9.0	8.5	13.0	12.0	10.5	4.5	12.5
Total No. points	100	71.0	73.5	76.0	79.5	74.5	55.0	80.0

A.—Favorableness to travel is dependent chiefly upon smoothness and freedom from dust and mud; secondarily upon the qualities composing "Acceptability."

B.—Acceptability includes noise, reflection of light, radiation of heat, emission of unpleasant odors, etc. It chiefly concerns the pedestrian and the adjoining resident.

ordinary conditions. It is sanitary, noiseless, easily kept clean and has a certain springiness lacking in asphalt, and is much easier on horses' feet. Expert labor is not required in its laying and the cost of maintenance is practically nil, so that from the standpoint of cost as well, it compares favorably with the asphalt, macadam and brick now being used in Canadian towns and cities."

It is interesting to note that Minneapolis is laying approximately 215,000 sq. yds. of pavement this summer, over 82% of which is creosoted wood block.

Scoria Block.—This type of pavement is wearing lightly and evenly in Toronto, and is satisfactory for most kinds of traffic. Hamilton paved some street intersections in 1899 with this block, but replaced them later with wood block. Ottawa's scoria block pavements is wearing into holes, but Mr. Currie attributes this to a possible use of poor concrete on soft sub-grade, when the pavement was put in place. Scoria block appears to possess disadvantages due to slipperiness in unseasonable weather, and noise at all times.

Toronto has stone pavements in use since 1881. They are cobbling but are indicative of indefinite wear.

Concrete.—Concrete pavement is of comparatively recent date, no report indicating its use in Canada prior to about five years ago. One feature of the opinions concerning it is its durability. Many cities have begun its use but no repairs have been necessary, especially if carefully laid. The general expression of engineers upon this pavement is one of favor and satisfaction for residential streets and moderately heavy traffic. Mr. Owen McKay, town engineer, Walkerville, Ont., advises the use of reinforcing at the expansion joints, and several suggest continuous reinforcing throughout with steel plates at the joints. The pavement is very easily cleaned with broom or flusher. Chatham reports that a pavement put down in 1908 has cracked longitudinally with the street, and is wearing at the juncture of the crack with the expansion joints. No repairs have yet been made, but it is the intention to fill these cracks with asphalt at an early date.

The durability of concrete pavements is illustrated by a recent press reference to a road from Detroit to Dearborn, ten miles in length, constructed of macadam, asphalt macadam, and concrete. Here it was found that the concrete pavement which had been in use for about four years was greatly superior in surface to the others, which had not been in service for more than half that period. In another instant a piece of macadam laid less than a year ago at a cost considerably exceeding that of concrete, was in a much inferior condition to a strip over the same territory constructed of small stone and concrete some four years ago, and it is claimed that no road in Michigan excels this particular piece of concrete pavement. Concrete roads have proved so successful in Wayne county, Michigan, that hardly any other kind is now being laid.

Some Opinions From United States.

We quote the following from a number of letters which have furnished us with information concerning the use of various pavements in cities of the United States.

Capt. Mark Brooke, U.S. Corps of Engineers, and assistant to the Engineer Commissioner of the District of Columbia, expresses his belief that sheet asphalt should be expected, under ordinary conditions, to attain a life of approximately twenty to twenty-two years, although in some instances in Washington it runs over thirty years. He believes that asphalt block, if well laid, should approximate the same life. They have more sheet asphalt in that city than any other type, and on the whole it is as satisfactory as any.

Mr. Wm. H. Connell, chief of the Bureau of Highways and Street Cleaning, of Philadelphia, considers asphalt as a very desirable pavement on ordinary medium traffic streets where grades are not too heavy. He is putting in wood block pavements on streets with very heavy traffic, especially where it is desirable to have a quiet pavement and where a finely dressed granite block pavement would be too noisy, and is finding it very satisfactory under such conditions. Sheet asphalt is being used very largely in Philadelphia, as is shown by the following statement of mileage and yardage of the various types in use:—

Character.	Miles.	Sq. yds.
Granite block	352.99	6,653,532
Asphalt (sheet)	472.35	6,959,656
Asphalt (block)	7.49	72,532
Vitrified brick	163.63	2,376,224
Cobble	14.02	162,775
Rubble	6.69	93,182
Slag block	8.13	78,071
Cement and granolithic	11.03	54,242
Wood block	4.06	121,505
Totals of improved pavements	1,040.39	16,571,719

Mr. John B. Hittell, chief engineer of streets, Chicago, estimates the life of the various pavements principally used there to be as follows:—

Asphalt	12 to 15 years
Brick	12 to 15 years
Creosoted block	15 to 18 years
Granite blocks	30 to 40 years

Chicago has laid, up to the present time, more asphalt pavement than any other type. Under normal conditions granite block is considered the most durable for heavy traffic and asphalt for light traffic.

Mr. Nelson P. Lewis, chief engineer to the Board of Estimate and Apportionment, of New York City, states that the average life of an ordinary sheet asphalt pavement in the borough of Manhattan may be considered to be fifteen years, and about eighteen years in other boroughs. Asphalt is very extensively used, probably more than all other types of pavements combined. It is found most suitable for resident streets and where it is difficult to maintain good sanitary conditions.

Next to this comes stone block which, if well laid, should withstand very heavy traffic for at least twenty years, and under lighter traffic, unless frequently torn up for the laying of mains, etc., it should last thirty years or more. If laid on a concrete foundation it is found to be most suitable for very heavy traffic, although wood block has been found to be the satisfactory pavement on light grades. Of this type he does not express an estimate of its life as it has not been in use sufficiently long. There is every indication, however, that if well laid and not disturbed it will be as durable as stone block.

The United States Bureau of Agriculture issued a bulletin this summer containing, as a result of an enquiry as to the opinions of a number of city engineers in the United States, the following table, in which under the percentage column the various qualities desired in a pavement are assigned proportionate values, the total being 100 points. The pavement ranking first under any given quality is given the full quality percentage, the rest grading down from this value in proper proportion.

Returning to our Canadian cities, Mr. A. F. Macallum, city engineer of Hamilton, Ont., states that the standard pavements used there are wood block, asphalt, and a form of asphalt-macadam. Brick is used only in alley-ways. Sheet asphalt exceeds other types in quantity and is considered the best under normal conditions. It is used on light traffic streets, except on grades exceeding two per cent., where asphalt-macadam is laid instead. For very heavy traffic wood block is used.

Concerning the life of the asphalt pavement, Mr. Macallum states that it is very difficult to arrive at an estimate unless the conditions specified in its construction are very carefully followed. Some pavements of this type have been down for fifteen years and are in excellent condition, while others, down for only three years, are not in good condition, due principally to a poor mixture of sand used. The principal difficulty experienced there has been in securing a good, clean combination sand that will give a sufficiently dense pavement. Mr. Macallum holds this to be a most important thing in asphalt pavement work, as at present the asphalt itself is made to such a standard that, if the proper penetration is used, there is no danger in that proportion of the pavement.

He cites an experiment on one pavement of using no binder, but described it as unsuccessful, as the pavement moved and formed an undulating surface under traffic.

Judging from the manner in which treated wood block pavement, which has such a comparatively recent history, has stood the test of the heaviest traffic in that city for the past four years, Mr. Macallum places its life at what he considers to be a very conservative estimate, 10 years.

He adds that asphalt-macadam and other pavements of that nature depend for their lives altogether upon the hardness and toughness of the stone, which will vary a great deal according to the vicinity from which the stone is secured, the limestone from their own quarries being too soft for such a purpose.

Table II.

Opinions of Canadian city engineers concerning the suitability of various pavements as they have been used for different conditions of traffic. (Arranged in descending order of present popularity):—

Light Residential to Semi-Business:
Sheet asphalt, bitulithic, asphalt concrete, asphalt block, wood block, concrete.

Semi-Business to Medium Heavy Traffic:
Bitulithic, sheet asphalt, asphaltic concrete, wood block, asphalt block, concrete.

Heavy Traffic:
Brick, wood block, stone, and scoria block.

Along Street Railway Tracks:
Wood block, brick.

Quiet Streets:
Wood block, bitulithic, sheet asphalt, asphaltic concrete.

Graded Streets:
Brick.

The city of Winnipeg has more sheet asphalt pavements than all others combined, and it is considered the best pavement for the city's use from all points of view. The first asphalt pavements were laid in 1897, one upon a residential strees, and one in the heart of the wholesale district. Both are still in perfect condition. In 1911, pavements consisting of two inches of asphaltic concrete on a 4½-inch cement concrete base were laid. Mr. H. N. Ruttan, city engineer, states that no pavement will withstand heavy traffic in Winnipeg without concrete foundations. Cedar block has been used principally in lanes, where it is standing seven to ten years' wear.

Table III.—Opinions as to Nature of Deterioration.

Asphalt Block:
Edge-wear forming holes and cobbles; worn pavement noisy and hard to keep clean; disintegration of bottom of blocks.

Asphaltic Concrete:
Wears into holes; susceptible to marking in hot, sunny weather.

Bitulithic:
Wears evenly, with a tendency to holes under heavier traffic; susceptible to surface marks in hot weather.

Brick:
Edge-wear and cobbling under heavy traffic; increased noise and unsanitariness as wear increases; when worn badly it slows down traffic.

Sheet Asphalt:
Wears slowly into large holes or patches; heavy traffic causes ruts; cracks hasten deterioration.

Wood Block:
Rots rapidly if untreated, retarding traffic; treated block wears slowly and evenly; frost intrusion causes buckling.

Stone and Scoria Block:
Wears gradually into holes and cobbles; unsanitary when roughened.

Concrete:
Wear is slow and even if well placed; cracking and chipping develop otherwise.

The Bonding of Pavements.

There is a wide diversity among Canadian municipal authorities as to the number of years that each type of pavement should be bonded, asphalt block, for instance, being subject to bond requirements extending from five to twenty years although, generally speaking, its lifetime is not expected to exceed more than twelve or fifteen years. In the majority of instances a five-year bond is the policy followed for all types of pavement; some of the larger cities, however, requiring a ten-year bond on most of them. Regina, previously ten years, has reduced its requirement to five; St. Boniface, Man., on the other hand, requires a bond extending twenty years. In the case of London the majority of bonds has been for ten years, but as the Guarantee Companies now decline to bond contractors beyond five years one is taken for that length of time for sixty per cent. of the amount of the contract, the contractor still requiring to guarantee his pavement for ten years, the city retaining six per cent. of the contract price for that period and paying annually the contractors' interest on the guarantee, providing the terms thereof are complied with.

In Ottawa ten per cent. of the contract price is held as guarantee for ten years, the average lifetime of asphalt and wood block pavements being considered fifteen years and Nepean stone and Scoria block pavements twenty years. In Toronto, fifteen per cent. is withheld for ten years.

Table IV.—Consensus of Opinion as to Durability.

Pavement.	Small repair. Years.	Extensive repair. Years.	Complete reconstruction. Years
Asphalt block	5 to 10	10 to 12	12 to 15
Asphalt concrete	4 to 6	6 to 8*	8 to 10*
Bitulithic	5 to 8	10 to 15	15 to 20
Brick	8 to 10	10 to 15	15 to 18
Concrete	5 to 8	10 to 12	15 to 18*
Scoria block and stone	10 to 15	15 to 20	20 to 30
Sheet asphalt	4 to 8	10 to 15	15 to 18
Untreated wood block	3 to 5	6 to 10	10 to 12
Treated wood block	8 to 10	12 to 15	15 to 18*

*These pavements have not attained an age in Canada sufficient to place the figures beyond conjecture.

Financing of Pavements.

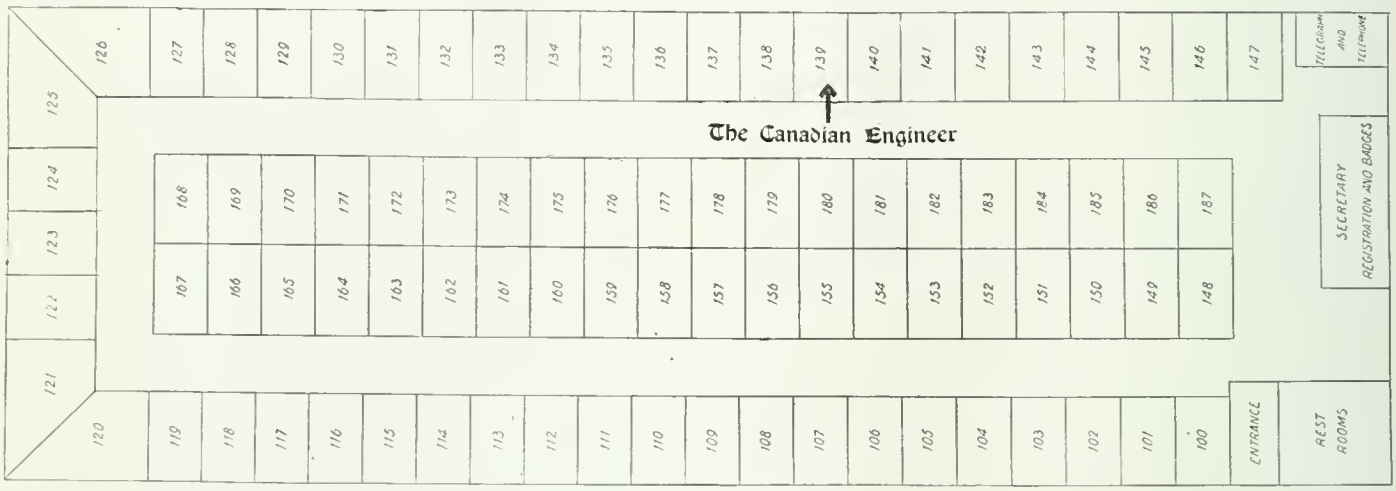
Hamilton does all its paving by day labor and, estimating the life of a pavement at ten years, bonds are issued against them for that length of time. In Toronto ten years is also considered as a fair estimate, and ten-year debentures are issued to finance them. In Winnipeg practically all paving is done by day labor. The money for paving is secured in all cases by the sale of thirty to fifty-year stock, i.e., the city may redeem any time after thirty years to fifty years. The term of assessment on sheet asphalt pavements is fifteen years, on asphaltic concrete, ten years; on cedar block pavement, seven years.

It is interesting to note that the city of New York has assessed the entire cost of the first pavement upon the abutting property and has paid from city funds the cost of all subsequent renewals, raising money for this purpose by the issue of fifty-year bonds. This policy is discussed at considerable length in the report of the Board of Estimate and Apportionment for 1912. Since then, however, the city has decided to limit to ten years the bonds issued to meet the costs of re-paving.

Washington's pavements are paid for in cash under appropriations made by Congress, the funds being derived from revenues of the District of Columbia, and a contribution on the part of the General Government on the basis of its ownership of property.

Philadelphia and Chicago issue five-year bonds against their pavements of various types.

THE CANADIAN ENGINEER AT THE DETROIT ROAD CONGRESS.



Plan of Exhibition Building.

The Canadian Engineer will exhibit at the Third American Road Congress at Detroit. Canadian visitors to the Congress are invited to make Booth No. 139, *The Canadian Engineer* headquarters, their headquarters also, during the week. Mail, telegrams, packages, etc., may be addressed care of *The Canadian Engineer*, Booth 139, American Road Congress, Wayne Gardens, Detroit.

NEW YORK'S PROBLEM OF SEWAGE DISPOSAL.

The pollution of New York harbor by the sewage from the metropolitan district has been gradually increasing, and it is recognized that steps must soon be taken to correct the conditions. In 1906 the New York State Legislature passed a bill requiring the city of New York to appoint the Metropolitan Sewerage Commission to study the pollution of the harbor and devise a proper method of correcting the conditions. The magnitude of the work of this commission may be realized when it is understood that the area studied is some 700 square miles, with a present population of about 6,000,000, and a future population of about twice this figure. Within the metropolitan district there are over 100 cities and towns, and the sewage produced is about 765,000,000 gallons per twenty-four hours. It is assumed that within thirty years the daily volume of sewage flow will be increased to 1,500,000,000 gallons. Of course, the volume of water in the harbor will not increase to furnish available dilution, and unless proper provisions is made for treatment of the sewage, a general intense pollution of the harbor is inevitable. The scope of the work of the Metropolitan Sewerage Commission includes a study of the facts and the formulation of a remedy for the existing and future conditions. As the work has progressed it has been found that the problem is of much greater magnitude than was at first anticipated, and several years' further study may be required before a final decision is reached.

BOOK REVIEWS.

The Elements of Specification Writing.—By Richard Shelton Kirby, C.E., Professor of Civil Engineering, Pennsylvania College. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Limited. Publishers' agents for Canada, Renouf Publishing Company, Montreal. Cloth, 6 x 9 ins.; pp. vii. + 125. Price, $1.25 net.

Reviewed by C. R. Young, B.A.Sc.

Although a number of excellent works on the subject of engineering contracts and specifications have been issued within the past few years, Professor Kirby's book easily surpasses any of them as a text for students or beginners in the art of specification writing. The ground covered in it is only such as should receive attention in an engineering college, and the manner of presentation leaves little to be desired. This excellence of treatment is no doubt largely due to the fact that the work is the outcome of a series of lectures delivered by the author annually for the past six years.

An outline of the matters treated will indicate the comprehensive character of this compact little treatise. As an introduction to the subject, construction work is classified according to the character of the financial arrangement between the Owner and the Contractor, and the documents incident to a contract are enumerated and described in brief. The author then proceeds to discuss the legal essentials and the composition of a contract, the surety bond, the notice to contractors, information for bidders, and the proposal. Since the specifications are, to the engineer, the most important part of the contract, the author very properly devotes the major portion of his book to the consideration of their composition and subject-matter. General clauses are treated fully, a proceeding rendered possible by the fact that their character has been the cause of a strong movement towards uniformity during recent years. Specific clauses covering all manner of construction, materials and apparatus cannot be treated in anything but a general manner in a short text, and for this reason the author has contented himself with a few pages of general directions and the outlines of specific clauses required in specifications for sewers, roads and pavements, pipe lines, bridges and similar typical undertakings. The work is concluded by a useful list of references in periodical literature to the subject of contracts and specifications.

The value of Professor Kirby's book lies chiefly in its being a concise, well-ordered presentation of the principles underlying the preparation of specifications. It is not a collection of specifications, nor a legal treatise, but such a book as might be placed in the hands of an engineering student to give him an idea of what is really meant by specification writing. Sufficient examples are given to illustrate the principles and to serve as models, except in the case of the specific clauses, where, for considerations of space, this is not done. Reference to the pages of high-class technical journals, for these in reality introduce another educative factor commensurate with the knowledge of the particular subject obtained. The manifest fitness of this little book as a text for engineering colleges will no doubt result in its extensive adoption for that purpose.

Simplified Formulas and Tables for Floors, Joists and Beams; Roofs, Rafters and Purlins.—By N. Clifford Ricker, Professor of Architecture, University of Illinois. Publishers—New York: John Wiley & Sons, Inc. London: Chapman & Hall, Limited. Publishers' agents for Canada, Renouf Publishing Company, Montreal. Cloth; 6 x 9 ins.; pp. vi. + 77. Price, $1.50 net.

Reviewed by C. R. Young, B.A.Sc.

Like his larger work on roofs, this book of formulas and tables was evidently intended by the author for the use of architectural students and beginners in structural design. The structural engineer will find in it little which he has not already in one form or another. In some instances the methods of computation are much less expeditious than those in common use by structural designers.

The work which the author undertakes is to present simplified formulas for the computation of the section moduli, moments of inertia, total safe loads and limiting spans of beams in various materials and subject to various end conditions. Simplification is brought about by expressing lengths and distances in feet, loads in tons, constants for the material in tons per square foot and bending moments in foot-tons. The numerical coefficients are thus reduced to comparatively small quantities, rendering slide-rule computations easy and short. The resulting formulas are then arranged in tables extending across both pages, and covering the use of steel, cast-iron, Washington fir, hemlock, white oak, long-leaf pine, short-leaf pine, white pine and spruce. Preceding these tables are thirty pages of explanatory matter, and following them are tables or properties of cast-iron lintels and a table of four-place logarithms for those who do not use the slide rule. The application of the formulas to the design of floor joists, flooring, sheathing, rafters, purlins and lintels is made plain by examples.

Although the subject-matter is well presented in the main, certain indications of lack of care in preparation exist. On page 1, l is defined as the *clear* span in inches of the beam, while on page 4, L, which is obviously $l \div 12$, becomes

the "length of beam in feet, or distance between *centres* of beams." In the example on page 3, the required moment of inertia on the basis of limiting deflection is computed without stating for the guidance of the student what the maximum permissible deflection is in this case. The following beginning to a sentence is not particularly auspicious: "Also, that if these formulas can be materially simplified, much time and labor can be saved, and it may become . . ."

Apart from the cases which can be solved much more simply by reference to tables in existing handbooks, the matter presented in Professor Ricker's book will be found useful for the architectural draughtsman and junior structural designer, provided no building regulations prevent the adoption of the working stresses on which the simplified formulas are based. Where this does occur, some assistance may be obtained by deriving new simplified formulas from the general formulas which the author gives.

The Improvement of Rivers: A Treatise on the Methods Employed for Improving Streams for Open Navigation, and for Navigation by Means of Locks and Dams.—By B. F. Thomas and D. A. Watt, United States Assistant Engineers. Published by John Wiley & Sons, Inc., New York. Publishers' agents for Canada, Renouf Publishing Company, Montreal. Second edition, two volumes; 713 pages of text, 346 illustrations and 84 appended plates; cloth; 9 x 12 ins. Price, $7.50 net.

There are eighteen chapters in all having the following titles:—

Part I.—Characteristics of Rivers—Regulation—Dredging and Snagging—Dikes—Protection of Banks—Levees—Storage Reservoirs—Improvement of the Outlets of Rivers.

Part II.—General Design and Construction of Locks and Dams—Locks—Lock-gates and Valves—Fixed Dams— Movable Dams—Chanoine Wicket Dams—Gate and Curtain Dams; Bridge and Shutter Dams—Drum Wickets, Bear Traps, Rolling Dams—Accidents to Structures.

Both volumes are models of typographical excellence, and the editing and arrangement of subject-matter is admirable. One pleasing feature is an unusually complete system of cross-referencing, which enables the reader to find expeditiously all that the work contains with reference to any particular subject.

This book is remarkable in that it epitomizes world-wide engineering practice in river regulation and improvement. The method of treatment is distinctly practical throughout, and the chief merit of the books lies in the multitude of practical ideas which the encyclopedic scope of the work makes accessible to the reader. While there is much in both volumes of interest to hydraulic engineers generally, the nature of the subject dealt with makes them particularly valuable and interesting to engineers engaged on governmental and other public works. To them the book is confidently recommended.

The first volume consists of eight chapters, devoted principally to the discussion of river improvement for open navigation, "Improvement by Regulation" being the subtitle of this portion of the work. Chapters I. and II. are of an introductory nature, containing a more or less academic discussion of river characteristics, and a brief description of various schemes of regulation in use on the larger rivers of Europe and America. The remaining chapters, as their titles indicate, are devoted to the discussion of the various methods now in use for providing and maintaining open navigation on navigable streams. In Chapter X. the principles which govern the economic use of storage as an aid to navigation are covered in a general way.

As related to navigation alone, there is nothing in the first volume of vital interest to Canadian engineers, as it deals almost exclusively with navigation on silt-bearing streams, notably the Mississippi, and problems of this nature are rare north of the international boundary. The value of the first volume lies rather in the fact that the various metrods outlined for the improvement of open navigation can be effectively and economically applied to the prevention of flood damage on non-navigable rivers.

Volume II. consists of ten chapters covering river improvement by means of locks and dams, "Improvement by Canalization" being the sub-title. Chapter I. is devoted to general discussion of the principles of design. The succeeding chapters, entitled as above, cover the subjects dealt with more or less in detail. Most of the chapters furnish cost data, and also a considerable amount of mathematical discussion.

The chapter on fixed dams is too brief to be of much value, the intention of the authors being doubtless to indicate, in a general way only, the functions of fixed dams in connection with canalization, rather than enter into the details of a wide subject already well covered by Wegmann Schuyler et al.

The chapters on movable dams constitute the most interesting and important feature of the second volume, the various types now in use in Europe and America being described at length and amply illustrated.

The possibility of using this type of dam in Canada for the development of mill powers on torrential rivers is worthy of very serious consideration, and it is safe to say that no single publication extant contains more information bearing on this question than the work under consideration.

Engineering as a Profession: Scope, Training, and Opportunities for Advancement.— A. P. M. Fleming, M.I.E.E., and R. W. Bailey, Wh. Sc., Principal of the Technical Institute, Crewe, England. Published by John Long, Limited, London. 288 pp.; 4½ x 7½ ins.; cloth. Price, 75 cents, post paid.

"While much has been written as to the manner in which the technical and practical portions of an engineer's training should be co-related so as to ensure the best results, very little has previously been written setting forth the facilities that actually exist for obtaining the most satisfactory training and employment."

The book sets about to supply this deficiency by giving a broad, general outline of the fields of engineering activity, by discussing modern methods and facilities for obtaining a thorough training, and by enumerating suitable apprenticeship courses and scholarships for those who are and those who are not in possession of sufficient means for a university training.

It must be admitted that the major portion of the book deals exclusively with conditions and facilities for training in the British Isles, thus rendering its value to young men elsewhere as that for general information only. But its clear-cut classification of the various channels which a young engineer may follow up makes it a most acceptable addition to his library. The chapters concern: The Engineering Profession; The Training of the Engineer; Facilities for Obtaining Education and Training for a Minimum Financial Outlay; Engineering Appointments; Foreign Methods of Training Engineers; and Modern Developments in Engineering Training and Employment.

The curriculums of English technical institutions, the enumeration of Government and professional appointments, and the summary of apprenticeship courses for various branches of the profession, contained in this book, make it a useful one for university and professional men in any country.

CATALOGUES RECEIVED.

The Valve World.—Illustrated bulletin for the month of August. Issued by the Crane Company, Chicago.

Duntley Electric Grinders.—Illustrated bulletin. Issued by the Chicago Pneumatic Tool Company, 1010 Fisher Building, Chicago, Ill.

Foos Junior.—Illustrated catalogue dealing with gas and gasoline engines. Issued by the Foos Gas Engine Company, Springfield, Ohio.

Q. E. F. Runway.—Illustrated catalogue describing runway. Issued by the Herbert Morris Crane and Hoist Company, Limited, Toronto.

American Vanadium Facts.—Illustrated bulletin describing different uses of vanadium. Issued by the American Vanadium Company, Pittsburg, Pa.

Abram Cement Tools.—25-page catalogue describing the company's sidewalk finishing tools. Issued by the Abram Cement Tool Company, Windsor, Ont.

Universal Bulletin.—Describing pouring of concrete for the Ford Motor Service Building, Chicago. Issued by the Universal Portland Cement Company, Chicago, Ill.

Adjustable Speed Direct Current Motors.—Technical bulletin describing company's adjustable speed direct current motors. Issued by the General Electric Company, Schenectady, N.Y.

Chicago Pneumatic Power-driven Compressors.—Illustrated bulletin describing the different kinds of compressors. Issued by the Chicago Pneumatic Tool Company, 50 Church Street, New York.

Curtis Steam Turbines.—15-page illustrated catalogue describing the Curtis steam turbines, from 100 k.w. to 2,500 k.w. capacity for driving 60-cycle generators at 3,600 revolutions per minute, special features of construction and steam extraction. Issued by the General Electric Company, Schenectady, N.Y.

Continuous Current Dynamos and Motors.—A pamphlet, No. 18 B, of Bruce, Peebles & Company, Limited, Edinburgh, dealing exclusively with machines of the open type, including a full detailed specification and supplemented by tables of weights and dimensions for different frame sizes, list of ratings, etc. The publication is well illustrated and contains interesting technical data. Bruce, Peebles & Company, Limited, engineers, Edinburgh, Scotland.

The Heenan Refuse Destructor.—A 32-page catalogue dealing with the disposal of garbage, rubbish, etc., by the H. & F. Destructor. The catalogue is well illustrated with photographs of many installations in Canada, United States and Great Britain, some of them having the capacity of several hundred tons. Reading matter is instructive respecting modern methods of refuse collection and disposal, and illustrated uses to which clinkers produced by the H. & F. destructor may be put in building operations, etc. Published by Heenan & Froude, of Canada, Limited. Laurie & Lamb, managers, Board of Trade Building, Montreal.

PUBLICATIONS RECEIVED.

Fur Farming in Canada.—By J. Walter Jones, B.S.A. Published by the Commission of Conservation, Canada. Committee on Fisheries.

Ontario Railway and Municipal Board.—Seventh annual report to December 31st, 1912. Issued by the Ontario Railway and Municipal Board, Toronto, Ont.

Employers' Welfare Work.—Bulletin No. 123. Issued by the United States Department of Labor Bureau of Labor Statistics, Washington, D.C.

Fourscore Years.—Illustrated publication, containing a record of the company's contribution to industrial engineering. Issued by Lockwood, Greene & Company, 60 Federal Street, Boston, Mass.

Fifth Census of Canada, 1911.—Volume III., pertaining to manufacturers for all the industrial establishments having five employees or over. 432 pages, 6 x 9 ins.

Ontario Land Surveyors.—Annual report of the Association and proceedings of the twenty-first annual meeting, held in Toronto, February last. Published by the Association of Ontario Land Surveyors.

Tar and Wood Journal.—Special by-product number, which may be obtained by any reader interested in the wood, tar and allied trades on application to the Swedish Chamber of Commerce, 5 Lloyd's Avenue, London, E.C.

Union Scale of Wages and Hours of Labor.—120-page bulletin on scale of wages and hours of labor from 1907 to 1912. Issued by the United States Department of Labor Bureau of Labor Statistics, Washington, D.C.

Electricity on the New York Central.—Descriptive booklet, which illustrates and describes the important features of electricity as used by the New York Central system. Issued by the General Electric Company, Schenectady, N.Y.

Mining Operations in Quebec Province.—Report for 1912 of the Mines Branch, Department of Colonization, Mines and Fisheries, Province of Quebec, reviewing the entire industry for the past year. Supplemented with illustrations, maps and appendix.

Mines and Mining.—Bulletin No. 61, containing abstracts of current decisions on mines and mining from October, 1912, to March, 1913, by J. W. Thompson. Issued by the Department of the Interior, Bureau of Mines, Washington, D.C.

Game and Fur-bearing Animals.—A 166-page book, 6 x 9 ins. in size, and fully illustrated with photographs and maps, descriptive of fur-farming in Canada, and containing sections devoted to preparation of skins for manufacture, commerce in raw furs, Canadian legislation, and statistics of fur production.

Mining Operations in Quebec.—Report for the year ending December 31st, 1912, by Theo. C. Denis, Superintendent of Mines. Contains statistical tables and a review of the mining industry in the Province of Quebec. Issued by the Mines Branch, Department of Colonization, Mines and Fisheries, Ottawa.

Waterworks of Canada.—Compiled by L. G. Dennis, B.Sc., Hydro-Electric engineer of the Commission of Conservation. Published by the Commission, Committee on Waters and Water Powers. Presenting in suitable form for reference principal physical data respecting all waterworks systems in existence in the Dominion, and classified according to Provinces. The report is illustrated, and occupies 108 pages, 6 x 9 ins.

CANADIAN FIRM BUYS AMERICAN FACTORY

By adding to their factory, at one stroke, the entire equipment of another telephone cable-making factory, the Eugene Phillips Electrical Works, of Montreal, have greatly increased their capacity. The Phillips company completed recently the building of a quarter of a million dollar extension to their Montreal plant, and then equipped it by installing all of the machinery that had been previously used by the Stromberg-Carlson Telephone Manufacturing Company, of Rochester, New York, in their telephone cable-making branch. This branch of the Stromberg-Carlson business was purchased outright by the Montreal firm.

The Eugene Phillips Electrical Works have been making telephone cable for about twenty-five years, but the addition of the Stromberg-Carlson machinery gives them sufficient output to handle very large contracts.

COAST TO COAST.

Winnipeg, Man.—A resolution introduced by H. D. Picket, Moose Jaw, at the recent convention of the Associated Boards of Trade of Western Canada, asking that the Dominion Governments of Ontario, Manitoba, Saskatchewan and Alberta provide for the construction and maintenance of a good vehicular highway between the Great Lakes and the Pacific Coast was passed unanimously, it being considered that such a road was needed, and would help the commercial and general interests of the country.

Kenora, Ont.—The engineers of the International Joint Commission, Arthur V. Arthur, Toronto, and A. F. Myers, Minneapolis, accompanied by Douglas N. McLean, of the Manitoba Hydrographic Survey, have examined the evidences relating to water levels here, and have inspected the new gauges which have been established. Arrangements were also made to start some survey parties from Kenora to examine places bordering on the shore of the lake, which might be affected by holding the water of the lake at various stages. Survey parties will begin operations at once.

Ottawa, Ont.—The whole question of the pollution of lakes, rivers and all navigable streams will be considered by an interprovincial conference, to be held in Ottawa in October. The Bradbury committee on the pollution of streams, which heard considerable evidence from experts and others on the matter last session, recommended a conference to discuss all phases of the question, at which all the provinces would be represented, and Hon. J. D. Hazen, Minister of Marine and Fisheries, has sent out an invitation to the various provincial governments asking that this be done. It is expected that the conference can be got together in October.

Vancouver, B.C.—That the Canadian Northern Railway engineers had puzzled over every possible entrance to False Creek, and that all plans were being forwarded to headquarters in Montreal were the statements made by Mr. T. G. Holt, executive agent of the company, to the civic bridges and railways committee. Whatever plan was thought most feasible would be submitted to the Railway Commission, and, with other obstacles out of the way, work could be started in a few weeks. Mr. Holt explained that getting over the Great Northern tracks was the problem they had been up against. To use an overhead crossing or a subway raised difficulties of grade, and the Railway Commission would hardly likely consent to a level crossing, although, Mr. Holt said, that would facilitate matters considerably. As to the filling in of the bed of the creek, Mr. Holt said it would be necessary to know the plans of the Sewerage Commission for the route of the China Creek extension. Ald. Crowe, Vancouver's member of the Sewerage Commission, however, informed him that the Commission was taking up that question now and would have details worked out at an early date. It is the Commission's intention to run the sewer down Clark Drive instead of through the creek. Mr. Holt wished to have a coffer dam built across the creek to keep the silt in, and this will be looked into. A report of Mr. C. A. P. Turner, engineer for the Georgia-Harris bridge, stated that hard footings had been found five feet higher than expected, and that a saving of $1,200 could be effected. Plans of the ground are being got out, however, before the committee agrees to change.

Toronto, Ont.—The Provincial Highways Commission will begin its peregrinations at once in the interest of good roadways in Ontario. New York State will form the basis of study, although the first observations will be made in Quebec. Mr. W. A. Maclean will meet Commissioners McGrath and Rankin in Montreal, and the party will go over the King Edward Highway, which runs south of Montreal to the international boundary at Rouse's Point. This road is some forty miles in length. It is being constructed by the Quebec Government and will be completed this fall. Quebec has a Provincial highway system, under which the Government supplies the township organizations with machinery, equipment and instruction, but with slight financial assistance. When the Commission arrives at Albany an extended conference will be held with Mr. John N. Carlisle, Chief Superintendent of State Highways. The New York system follows the French method of maintaining a central highway department, which extends assistance to the municipalities. The main arteries of traffic are built by the State with small contributions from the counties.

Edmonton, Alta.—Most important of the legislation to be taken up at the coming session of the Alberta Legislature probably will be the building by the Provincial Government of the Alberta and Great Waterways Railroad from Edmonton to Fort McMurray, 230 miles, from which point the Athabasca, the Great Slave and the Mackenzie Rivers are navigable to Fort McPherson, 2,100 miles. The primary purpose of the railway is to afford adequate transportation facilities to settlers, prospectors and trappers in the north country and provide an easy outlet for their products, including grain, minerals and fur. The estimated value of the raw fur trade of the north alone is a matter of between $6,000,000 and $6,500,000, of which about 50 per cent. has come out by way of Edmonton this year, the rest going to the United States through traders from Seattle and San Francisco, who send ships into the Behring Sea and to Herschell Island. "There are many reasons why the railroad should be built to Fort McMurray at once," said a prominent supporter of the Government recently. "From what I can gather I should say that work may be started this fall and rushed to completion. The chief survey has been made, and it is only a matter of assembling men and materials. Every man who has ever been in the north country must be in favor of the plan, as it will ultimately mean a railroad from Edmonton to Dawson, connecting the Yukon country with the outside world."

Quebec, Que.—In view of the increasing attention which is being directed to the adoption of oil as fuel in the British Navy, it is interesting to know that oil lands in different parts of the Empire are being sedulously developed. The decision of the Government to secure supplies as far as possible within the Empire has given a new impetus to the search for large oil deposits in different parts of the dominions, and it would be fitting that the premier dominion, Canada, should be reckoned among the fuel-oil sources of supply. In this connection Viscount Selby, who is chairman of the Eastern Canada Company, and who has just returned from the Canadian fields, supplies interesting details. In the course of a conversation Lord Selby remarked that he was greatly impressed with what he saw and heard during the visit. The most favorably situated oil fields in Canada, from a geographical and strategical point of view, he states, are those of Gaspe, which extend from the seacoast on the Bay of Gaspe, on the Gulf of St. Lawrence, for several miles in a north-westerly direction. It was in the Larocque district, in the North-West, that a considerable number of wells were put down, and good supplies of oil of a high quality obtained. What is known as an anticlinal formation extends from this district in a south and easterly direction down to the coast. The opinions of experienced drilling men and geologists in that country are to the effect that oil will be found there in large quantities. Should this be the case, the importance of the field from the points of view of supply for the British Navy and for marine and industrial purposes cannot be overestimated.

Winnipeg, Man.—The condition of the road to Selkirk at the present time is not conducive to the best feeling on the part of the users of this particular stretch of highway.

The work of putting the road in first-class shape was well commenced by the Government engineers, and just when the road-users were congratulating themselves that at last a piece of road work was to be done in a sensible manner, they were disappointed to find that a number of cross culverts were put in all at one time and the trail almost rendered impassable for want of a little trouble on the part of those in charge of the construction. There is one portion of the road where a deep gully has to be traversed in order to get by the new bridgework, and in the event of rain it simply means that a vehicle is stuck on whichever side of the gully it happens to be, and it is necessary to secure the aid of three or four teams to get through. Another cause for dissatisfaction is the method of laying gravel. It is piled on the centre of the road to a depth of about four inches, and has some stone mixed with it big enough to make it dangerous for a car when the wheels strike them and they roll on the hard surface of the road underneath. This sort of work is not what might be expected of engineers who are in the service of the Government, and unless some radical steps are taken to alter the method of procedure, the work might just as well have been done by the old system of jobbing. It is a waste of the taxpayers' money to put up a road in such a shape that the expense of after maintenance is almost as heavy as the original cost of construction.

The Pas, Man.—The plans for the Hudson Bay Railway terminals at this point have been approved. P. Gordon, resident engineer, is understood to be on his way back from Winnipeg, and is bringing with him the plans of the terminals, showing the layout of yards, freight-handling plant, roundhouse, shops and other details. It is stated that the Government has acquired half a section of the Finger mill property and a considerable area to the north and east of The Pas annex. The shops, freight sheds and depot will be immediately adjoining the original townsite, and the receiving and sorting yards at the other end of the new property. It was originally proposed to acquire a portion of the Indian reserve property, a part of which was purchased for the townsite, to be used for terminal purposes. The Indians, however, asked such an inordinate price for their land that the Government went to the other side of the annex for a site. It is expected that connection will be made with the terminal site and the present terminal of the line through the original townsite.

Nelson, B.C.—Rich in minerals, timber and agricultural resources, Duncan River and Howser Lake districts, the development of which has been retarded for many years by lack of cheap and expeditious means of transportation, may in the not distant future be opened up by improvements to Duncan River which would make that stream navigable. R. F. Green, M.P. for Kootenay, is interesting himself in the project, and J. P. Forde, resident federal works public engineer for Kootenay, will visit the district for the purpose of reporting upon the advisability of making the waterway navigable from main Kootenay Lake to Howser Lake.

Vancouver, B.C.—Work on the boring of the "pioneer" Rogers Pass tunnel through Mount Donald, at Glacier, on the main line of the Canadian Pacific Railway, is being actively prosecuted, stated Mr. J. G. Sullivan, chief engineer of western lines for the company, who arrived in Vancouver recently. He remarked that 125 feet of the drift has already been scooped out. The Canadian Pacific Railway is piercing the mountain with a 22 feet by 30 feet tunnel, five miles long. The contractors are adopting a new method, which is being eagerly watched by engineering experts. The "pioneer" tunnel will run parallel to the main bore, and work will be pressed by means of cross-cut borings. A large force of men are engaged at the scene of the operations, and camps have been established on each side of the mountain. Steam shovels are being used to grade the approach to the western portal below Glacier Station. Mr. Sullivan will conduct a general inspection of the work being carried on in connection with the Vancouver terminal improvement schemes at Port Coquitlam, and also on the lines of the British Columbia division.

South Vancouver, B.C.—"That in the opinion of this council the establishment of a municipal electric plant is a pressing necessity, and would prove of great advantage to the interests of the municipality." This resolution was unanimously passed by the South Vancouver Municipal Council on the motion of Councillor Campbell, seconded by Councillor Third, after thoroughly dicussing a report brought in by Municipal Electrician Rawden to the effect that at an initial cost of $600,000 an electric light and power plant could be established in the municipality capable of providing for the needs of the district for the next five years, and stating that electric light could be supplied at seven cents per kilowatt hour, and at two cents per kilowatt on the day load for power purposes. Mr. Rawden recommends a two-unit steam generating plant of the turbo-generator units type, with a nominal rating of 2,000 kilowatts, and a maximum rating of 2,500 kilowatts, which, he estimates, would meet the needs of the municipality for the next five years. The cost of the plant, Mr. Rawden estimates, would be approximately $400,000 for the first unit, and $200,000 for the second unit. This would not include the cost of a building, which, Mr. Rawden suggests, could be either temporary or permanent, and should be situated near the Fraser River. Provision was made in the estimates for an adequate system of street lighting, including 300 arc lamps and standard lamps for Main Street, Cedar Cottage, Fraser Avenue and Collingwood. Mr. Rawden points out that there are over 8,000 connections using electric light and power in South Vancouver, and a large number of dwelling houses not at present using electric light.

Ottawa, Ont.—The report on the water supply will be ready for either the first or the second meeting of the city council in October. The British engineers, Messrs. Binnie and Tickell, are still here, but they are making such progress in their work that there is a good possibility of the report being ready early in October. The mayor has stated that the reports which will be presented to the city council will be most comprehensive, taking in Lake Deschenes and other proposals which have been made from time to time. There will also be a report as to what the Government is prepared to do, though it is understood that as yet the Cabinet has not discussed figures. When special legislation was secured for raising five million dollars for the work, the stipulation was that a two-thirds vote of the city council or endorsation by the people would be necessary. It is generally understood that the five million will not be sufficient, but it is also believed that there would be no difficulty in getting special legislation to expend a couple of millions more on the same condition. If the estimated cost is not too far over the five million mark, there seems quite a probability of the council by a two-thirds vote settling the matter for good. It is believed that most people would be glad of the water question not figuring as an issue in the coming municipal elections.

Sault Ste. Marie, Ont.—Continuing his official tour of inspection, Hon. Frank Cochrane, accompanied by Hon. W. H. Hearst, met the members of the Sault Ste. Marie City Council and the Board of Trade recently and discussed matters of importance regarding the future development of the Soo. The subject of an ice-breaker for the Soo for the purpose of assisting in keeping navigation open for a longer period in the early part of the winter, to facilitate the handling of the grain shipments from the West, was brought up, and the hearty support of the Minister of Railways and Canals was promised in the prolongation of the navigation season. In answer to an enquiry as to the proposed new ship

canal here, the Minister replied that the matter was as yet only in its initial stages, but there would be no use of the Government deepening the Welland Canal without also taking care of the shipping interests at the Soo. To a question as to the location of the proposed new lock, Mr. Cochrane thought it would be to the south of the present one, as the Government has expropriated all the land in anticipation of this. The influence of the Minister of Railways and Canals was solicited in preventing the narrowing of St. Mary's River by means of docks being built out past the deep-water line, as it is contended that all the space available is needed at present for the handling of the large vessels plying up and down the river.

PERSONAL

T. AIRD MURRAY, consulting engineer, Toronto, has been engaged by the town of Whitby, Ont., as engineer in connection with the proposed establishment of a sewer system.

STEPHEN MORRISON, mining engineer, Scotland, has opened an office in Victoria, B.C. Mr. Morrison is interested in British Columbia development, and believes in the development of Pacific commerce to relieve the congestion of shipping in the Atlantic.

J. KEELE, of the Department of Mines, Geological Survey, has returned from the West, where, in company with Dr. Heinrich Ries, professor of geology at Cornell University, investigation into the clay resources of Canada has been continued this summer.

ARTHUR H. BLANCHARD, M. Can. Soc. C.E., consulting highway engineer and professor in charge of the graduate course in highway engineering at Columbia University, and PREVOST HUBBARD, Assoc. Am. Soc. C.E., consulting chemist, in charge of the division of roads and pavements, the Institute of Industrial Research of Washington, and lecturer in highway engineering chemistry in Columbia University, have formed a partnership under the firm name of Blanchard & Hubbard, highway efficiency experts, with offices at Broadway and 117th Street, New York City. At present Messrs. Blanchard & Hubbard are retained by Commissioner John H. Delaney as the advisory board on highways for the New York State Department of Efficiency and Economy, and a few days ago the announcement was also made that they had been delegated to serve as members of the United States Committee on "Standardization of Nomenclature of Road Materials," which committee is to co-operate with the Engineering Standards Committee of Great Britain.

OBITUARY.

D. A. McCAW, of Welland, Ont., a third year student in civil engineering at the University of Toronto, died on September 15th after an illness of only several days' duration.

DONALD MATHESON, a young engineering student connected with a survey party in Northern Ontario for the Canadian Pacific Railway Company, died on September 20th as a result of blood poisoning from the bites of black flies.

JAMES ROSS, well known in engineering and financial circles, died at his home in Montreal on September 20th, 1913, after a short illness. Death was due to acute heart trouble.

Mr. Ross was born in Scotland in 1848, and, after completing his education there, spent a few years in railway, harbor and waterworks in England. He came to America in 1870, and became resident engineer of the Ulster and Delaware Railway, and subsequently was chief engineer. Mr. Ross was in turn connected with the Wisconsin Central Railway and the Lake Ontario Railway. He moved to Canada, and was appointed chief engineer and then elected general manager of the Victoria Railway. In 1878-1879 he built the Credit Valley Railway, and was its general manager. He was consulting engineer for the Ontario and Quebec Railway. Mr. Ross took control of the construction of the Canadian Pacific Railway west of Winnipeg in 1883, and in 1885 completed that line over the Rocky Mountains. He took up his residence in Montreal in 1888. Mr. Ross assisted in building many of the leading railways in Canada and in electrifying her street railways, such as those of Toronto, Montreal, Winnipeg, St. John, etc. He carried out work of a similar character in England and Jamaica, and was the first president of the Mexican Power Company, which developed an immense water power at Necaxa and controls the electric business of the city of Mexico. Subsequently he became president and active head of the Dominion Coal Company.

From among his numerous business connections it might be mentioned here that he was vice-president and managing director of the Montreal Street Railway; vice-president of the Toronto Street Railway, president of the Winnipeg and St. John Street Railways, president of the Dominion Bridge Company, vice-president of the Montreal Light, Heat and Power Company.

Although Mr. Ross had withdrawn from most of his business activities, he retained the presidency of the Dominion Bridge Company and St. John Railway until his death.

Mr. Ross was a member of the Canadian Society of Civil Engineers and also of the American Society of Civil Engineers.

ROYAL ARCHITECTURAL INSTITUTE

The Royal Architectural Institute of Canada closed its Sixth Annual Convention, held in Calgary, September 15th and 16th, with the following election of executive officers: J. H. G. Russell, Winnipeg, Manitoba, retains his office as president, and Alchide Chausse, of Montreal, is honorary secretary. The vice-presidents are Roland W. Lines, Edmonton, Alta., and J. P. Ouellette, Quebec. J. W. H. Watts, of Ottawa, is honorary treasurer.

Quebec was chosen as the next place of meeting, the date to be September, 1914.

COMING MEETINGS.

AMERICAN ROAD CONGRESS.—Annual Session will be held in Detroit, Michigan, from September 29th to October 4th. Secretary, J. E. Pennybacker, Colorado Building, Washington.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—Twentieth Annual Meeting to be held in Wilmington, Del., October 7th to 10th. Secretary, A. Prescott Folwell, 15 Union Square, New York.

UNITED STATES GOOD ROADS ASSOCIATION.—Convention will be held at St. Louis, Mo., November 10th to 15th. Secretary, J. A. Rountree, L021 Brown-Marx Building, Birmingham, Ala.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found sommaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

20252—September 5—Authorizing Lake Erie and Northern Railway Co. to construct across three (3) highways in Tp. Brantford.

20253—September 3—Amending Order No. 20134, dated August 16th, 1913, by inserting figures "65, 66, 67" before figures "68" in seventh line of paragraph 6 of said Order.

20254—September 5—Granting leave to Hydro-Electric Power Commission of Ont. to erect and maintain its 40,000 volt line across wires and across track of C.P.R., on Arthur Street, Elmira, Ont.

20255—September 4—Authorizing Edmonton, Dunvegan and B.C. Ry. Co. to construct across twenty-six (26) highways in Prov. of Alta.

20256—September 4—Approving plans and specifications of Morrison Drain to be constructed under Michigan Central R.R., Tp. Harwick, Ontario.

20257—September 5—Recommending to the Governor-in-Council for sanction Book of Rules of London and Lake Erie Ry. Co.

20258—September 3—Authorizing C.N. Alta. Ry. Co. to construct proposed spur to Wellman Gravel and Supply Co. across public road between Secs. 30 and 29, Tp. 54-1, W. 5 M., Alta.

20259—September 4—Authorizing C.N.R. to construct across Coteau St., City of Moose Jaw, Sask., by means of structure carrying highway over railway.

20260—September 3—Authorizing C.N.R. to construct spur for A. MacDonald Co., Ltd., from Loop Line on which Fort William Station is situated, across Vickers St., to serve Lots 417 and 418, Wiley Addition, Fort William, Ont.

20261—September 5—Authorizing C. N. Western Ry. to construct across C.P.R. main line in Sec. 2-13-6, W. 4 M., Alta., by means of overhead structure.

20262—September 4—Authorizing C.P.R. to construct additional track (double track) across Que., Montreal and Southern Ry. at mileage 18.81 from Farnham, on C.P.R. main line, Farnham, to St, Johns, Que.

20263—September 4—Authorizing C.P.R. to open for traffic portion of Weyburn Westerly Branch from Assiniboia, mileage 112, to Woodrow, mileage 145.7, Sask.; trains be limited to a speed not exceeding 18 miles an hour.

20264—September 4—Authorizing the C.P.R. to construct additional track (double track) of its main line, by means of a bridge, across C.N.O.R., at mileage 92.84 of C.P.R. main line, Toronto Subdivision, Ont. Division, in Lot 4, Tp. York.

20265—September 5—Approving location C.P.R. station at Dand, Man., on its Boissevain to Lauder Branch.

20266—September 4—Authorizing the C.P.R. to construct Bridge No. 19.00, near Mitigan, B.C., Shuswap Subdivision, B.C. Division and Bridge No. 97.2 over Vermillion River, near Larchwood, Ont., Lake Superior Division, Cartier Subdivision.

20267—September 4—Extending, until November 1st, 1913, time within which C.P.R. be required to complete work of diverting Nine Mile Road, in Lots 5 and 7, Con. 9, Tp. South Gower, Ont.

20268—September 3—Authorizing C.P.R. to open for traffic portion of double track, Farnham Subdivision from mileage 6.7 at Farnham, to mileage 18.7, at Iberville Jct., distance of 12 miles.

20269—September 3—Authorizing C.P.R. to construct Bridge No. 88.29, near Glacier, B.C., on Mountain Subdivision, B.C. Division.

20270—September 6—Authorizing C.P.R. to construct additional track (double track) of main line across Fifty-six (56) highways, mileages 55.39 to 110.5, Swift Current Subdivision; and Medicine Hat Subdivision, mileages 0 to 6.

20271—September 4—Authorizing G.T.P.Ry. to construct two spurs for Northern Lumber Company, in Block 12, Eastwood Addition, Edmonton, Alberta.

20272—September 4—Authorizing G.T.P. Branch Lines Company to construct and operate a wye, turning out from its Cutknife Branch at mileage 47, in N.W. ¼ Sec 10-45-23, W. 3 M., Dist. West Sask.

20273—September 5—Authorizing G.T.P. Branch Lines Company to carry traffic over portion of Regina-Boundary Branch, Sask., between Talmage, mileage 66.5 and Boundary line, mileage 155; trains operated over said line to be limited to speed not exceeding 25 miles an hour.

20274—September 3—Amending Order No. 19643, dated June 16th, 1913, by striking out words "Branch Lines Company," where they occur in recital to said Order, and substituting therefor words "Railway Company."

20275—September 3—Approving location G.T.P.Ry. stations, in Province of B.C.—namely, Mount Robson, mileage 1078.8 west of Winnipeg, Rge. 3, Albreda, mileage 1088.5 west of Winnipeg, Rge. 3, and Eddy, mileage 1127.6 west of Winnipeg, Lot 7236; and rescinding Order No. 19010, dated April 8th, 1913, in so far as it approves of said stations at Mount Robson and Albreda.

20276—September 3—Authorizing G.T.P.Ry. to construct its Lake Superior branch across highway between Lots 20 and 21, Con. 3, and Arthur Street, Tp. Neeping, Ont.

20277—September 4—Authorizing G.T.R. to construct siding to and into premises of Goodyear Rubber Company, town of Bowmanville, Ont.

20278—September 2—Authorizing G.T.R. to construct siding into premises of John Heney and Son, Limited, Ottawa, Ont.

20279—September 5—Authorizing G.T.R. to reconstruct bridge No. 113 over Coaticook River, at Mile Post 164.98, 2nd Dist., Que.

20280—September 3—Authorizing G.T.R. to reconstruct Bridge No. 241, at mileage 52.29, over Portage Creek, Parish of Dewittville, Co. Godmanchester, Que.

20281—September 3—Authorizing G.T.R. to construct siding commencing at a point on Middle Div. of its railway, and on Lot 23, in Tp. Raleigh, now in City of Chatham, Ont., thence extending in a westerly direction and connecting with C.P.R. spur line on said Lot No. 23, said branch line to be constructed within three (3) months from date of this Order.

20282—September 5—Authorizing G.T.R. to construct siding and spur therefrom, commencing at a point on its railway south of Main Street, town of Welland, extending in south-westerly and southeriy direction to an into premises of Canada Forge Company, Limited, on Lot 24, Con. 5, Tp. Crowland, Co. Welland.

20283—September 5—Approving and authorizing clearances of tramway at the Grand Trunk Railway Company's siding at Lindsay, Ont.

20284—September 5—Authorizing G.T.R. to construct siding into premises of MacDonald Thresher Company, Limited, Stratford, Ont.

20285—September 3—Authorizing Que., Montreal and Southern Ry. to use and operate bridge over St. Francois River, between St. Francois du Lac and Pierreville, Que.; provided trains operated over said bridge be limited to a speed not exceeding 5 miles an hour.

20286—September 4—Authorizing Q.M. and S. Ry. to construct branch line across St. Thomas St., town of Longueuil, to and into premises of D. Brisette and Company.

20287—September 3—Authorizing C.P.R. to construct spur for Dwyer Elevator Company, Limited, Fort William, across and along Sixth St. and across Third Ave., said City of Fort William, Ont., together with two sub-spurs on said Elevator's Company's lands.

20288—September 8—Authorizing G.T.R. to construct siding commencing at a point on that portion of its railway

known as "Ashbridge's Bay Spur," east of Cherry St., Toronto, Ont.; thence extending in a south-westerly and southerly direction along and across what is known as "The 150-foot Roadway," and across Keating's Channel, for a distance of 133 ft.; thence in a southerly and south-easterly direction a distance of 2,415 ft. in Toronto Harbor Industrial District, subject to certain conditions.

20289—September 5—Authorizing C.N. Western Ry. Co. to construct across C.P.R. main line in Sec. 18-13-6, W. 4. M., Alta, subject to certain conditions.

20290—September 5—Authorizing C.N. Western Ry. Co. to construct across C.P.R.Co.'s spur line at Redcliff, Alta, subject to and upon certain conditions.

20291—September 8—Authorizing C.P.R. to construct highway crossing over its railway opposite Ninth Ave., town of Blairmore, Alta; and rescinding Order No. 18368, authorizing Applicant Company to open up, at its own expense, original road allowance known as Twelth St., across its tracks.

20292—September 8—Authorizing Q.M. and S.Ry. to construct, subject to terms of consent of village of Montreal South, spur track for Messrs. Lapointe and Maillonx in said village of Montreal South.

20293—August 18—Approving revised location Edmonton, Dunvegan and B.C.Ry. from mileage 120.7 to mileage 122.88, through Tp. 70, Rge. 1, W. 5. M., Alta.

20294—September 8—Approving location Alberta Central Ry., from mileage 10 to mileage 20, Red Deer to Sounding Creek, being from Sec. 22-37-26, W. 4 M., southerly and easterly to Sec. 5-37-25, W. 4 M., Alta; and authorizing construction of said railway across eleven (11) highways.

20295—September 8—Rescinding last paragraph of Order No. 19532, dated June 9th, 1913, that free delivery area therein set out be replaced by following extended free delivery area: "Steelton: In the triangular portion bounded by Wellington St., John St. and Cathcart St., and on botb sides of Wellington St., from John St. to Hudson St."

20296—September 2—Directing that C.N.R. construct standard portable station and loading platform at Eriksdale, Man., work to be completed within 30 days from date of this Order.

20297—September 6—Authorizing C.P.R. to construct industrial spur and two sub-spurs for Manitoba Rolling Mills Company, Limited, being from mileage 20 of Winnipeg Beach Subdivision; thence in a south-easterly direction through river Lots 26 and 27 of parish of St. Clements, Manitoba.

20298—September 9—Extending, for a period of three months from date of this Order, time within which G.T.R. complete branch line into premises of Dominion Canners, Limited, Simcoe, Ont.

20299—September 9—Extending, until September 30th, 1913, time within which C.P.R. and G.T.R. install electric bells at crossing of Perth Road, one mile north of city of Kingston.

20300—September 9—Extending, until November 30th, 1913, time within which C.P.R. complete spur for Thomas Jackson and Son, Winnipeg, Manitoba, authorized under Order No. 19450.

20301—September 10—Authorizing C.P.R. to construct Bridge No. 24.20 over Crazy Creek, Shuswap, Subdivision, B.C. Division.

20302—September 9—Authorizing C.P.R. to construct, by means of a grade crossing, additional track (double track) of main line, Sask., Division, Swift Current, Subdivision, across highway between Sec 14-18 and Sec. 33-17-6, W. 3 M., at mileage 50.69.

20303—September 9—Authorizing C.P.R. to construct, by means of grade crossing, additional track (double track) of main line, Sask. Division, Swift Current Subdivision, across highway between Secs. 16 and 17, 17-9, W. 3. M., at mileage 80.97.

20304—September 9—Amending Order No. 19842, dated July 19th, 1913, subject to terms and conditions set out in letters of Mr. C. W. P. Ramsay, Engr. of Construction for C.L.O. and W.Ry., and Mr. E. W. Oliver, Ass't. to Chief Engineer of C.N.O.R., of date June 9th and 18th respectively, by striking out clause 2 of operative part of Order.

20305—September 10—Authorizing C.N.O.R. to construct bridge across Petawawa River (Middle Crossing), mileage 150.15 from Ottawa, Montreal-Port Arthur Line, Tp. Fitzgerald.

20306—September 10—Authorizing C.N.O.R. to construct bridge across Petawawa River (East Crossing), Tp. White, Ont., mileage 142.5, from Ottawa, on Ottawa-Capreol Line.

20307—September 11—Authorizing the C.L.O. and W.Ry. to swing a scaffold, temporarily, for thirty days from date of this Order, under the structure carrying its railway over the tracks of the G.T.R., at mileage 69.25, in Lot 3, Con.1, Tp. Tyendinaga, with a height of not less than 18 ft.

20308—September 9—Authorizing the C.L.O. and W.Ry. to swing a scaffold, temporarily, for thirty days from date of this Order, under structure carrying its railway over the tracks of the G.T.R., at mileage 121.52, Lot 23, Con. A, Tp. Hamilton, with a beight of not less than 18 ft.

20309—September 10—Authorizing the C.P.R. to open for the carriage of traffic that portion of the Suffield West Branch of its railway from mileage 00 to Terrace, a distance of 26.4 miles.

20310—September 9—Authorizing the C.P.R. to construct, maintain and operate a branch line of railway, or spur, to and into the premises of R. Graham and Sons (Shale Products, Limited), Lot 1, 2nd Con., west of Tp. of Caledon, Co. Peel, at mileage 19.6, Orangeville Subdivision, near Inglewood Jct., Ont.

20311—September 9—Extending the time within which the C.P.R. shall comply with the requirements of General Order No. 108, until January 1st, 1914.

20312—September 9—Authorizing the Quebec, Montreal and Southern Ry. to construct, maintain and operate branch line of railway or spur, for the Sir W. G. Armstrong-Whitworth Company, Limited, at Longueuil, Que.

20313—September 11—Authorizing the Cor. of the Tp of Brantford to construct at its own expense, a public highway to be known as "Linden Avenue," over the railway of the Brantford and Hamilton Electric Railway Company, within the limits of the Tp. of Brantford.

20314—September 11—Authorizing the Essex Terminal Ry. to construct its railway across Lloyd Ave., town of Ojibway, Ont., at rail level.

20315—September 10—Approving, subject to the conditions contained in the agreement between the G.T.P. and Isaac Greenizen, dated December 11th, 1912, the revised location of the G.T.P. station at mileage 422, Prince Rupert East, Lot 33, B.C.

20316—September 11—Authorizing the G.T.P. Branch Lines Company to carry traffic over that portion of its Tofield-Calgary Branch, Alta., between Beiseker, mileage 163, to mileage 197.7.

20317—September 11—Authorizing C.P.R. to construct, by means of a grade crossing, its Manitoba Division, Napinka Subdivision, across road allowance between S.W. ¼ Sec. 4, and S.E. ¼ Sec. 5-2-14, W.P.M.

20318—September 12—Granting leave to C.P.R. to terminate agreement, entered into between the company and Daniel Silver, dated December 1st, 1910, in pursuance of Sec. 12 of said agreement, under which siding was constructed to premises of Daniel Silver in S.W. ¼ Sec. 26-21-20, E.P.M. Manitoba.

20319—September 12—Authorizing the C.P.R. to change present grade crossing in road allowance between Lots 30 and 31, Con. 2, Tp. of Scarboro, and construct additional track (double track), by means of grade crossing, across said road allowance between Lots 30 and 31, at mileage 89.7 on main line, Toronto Subdivision.

20320—September 12—Approving standard 20-foot concrete arch of C.P.R., as shown on plan No. B-14-29, on file No. 23072.

20321—September 9—Approving location Edmonton, Dunvegan and B.C. Ry., station grounds in S.W. ¼, Sec. 34-55-25, W. 4 M., Alta; station to be located at a point 400 east of Rue Champlain, on north side of track, town of Morinville.

20322—September 11—Authorizing Essex Terminal Ry. Co., to construct, at rail level, across Weaver Ave. and Elliott Road, town of Ojibway, Ont.

20323—September 12—Authorizing C.N.R. to construct across public road between Secs. 22 and 27, Tp. 36, Rge. 10, W. 2 M., Thunderhill Branch.

Tarvia

Preserves Roads
Prevents Dust~

Overcomes Washing on a Heavy Grade

The above cut shows Russell Hill Road in Toronto, a water-bound macadam road with a heavy grade. Formerly great damage was done to the surface of this roadway by washing, and incessant repairs were required to keep it in satisfactory condition.

In June, 1912, a coat of "Tarvia B", at the rate of one-third gallon per yard, was applied. The Tarvia penetrated into the road surface and hardened, thus reinforcing the natural binder, cementing the surface together and making the surface shed water like the proverbial duck's back. The torrents which formerly had destroyed the surface now ran off harmlessly, and the road showed no further signs of washing. In addition, the surface remained practically dustless and gave superior resistance to automobile traffic.

Water torn roads are as unnecessary in these days as dusty roads. The up-to-date engineer knows how to prevent water damage and dust by the use of a bituminous binder. The best and most economical binder is Tarvia, a coal tar product especially prepared for road work.

There are three kinds of Tarvia:—"Tarvia X," very dense, for the large voids of new construction; "Tarvia A," for thorough resurfacing work; "Tarvia B," which was used in the above contract, for dust prevention.

In all cases the function of Tarvia is the same —to seal the surface against water, to give it an element of plasticity enabling it to resist automobile traffic, and to bind the stone together to prevent internal movement and attrition by traffic. Booklets on request. Address our nearest office.

RAILWAYS—STEAM AND ELECTRIC.

Fredericton, N.B.—Tenders will be received up till the 25th of September, 1913, for the erection of freight sheds and platforms. Plans and specifications may be obtained from the Department of Railways and Canals, Ottawa. L. K. Jones, secretary.

+—Montreal, Que.—The Canadian Pacific Railway has awarded GEO. A. FULLER CO. the contract for the erection of a station. The contract price is $150,000.

Montreal, Que.—The request of the Southern Counties Railway to extend its car line across McGill Street, east on Youville to St. Peter, and north on St. Peter to Youville Square, and thence west on the square to McGill Street, has been favored by the special committee of aldermen given its consideration.

Moose Jaw, Sask.—There is reason for believing that the Canadian Northern Railway will build another line through Humboldt, running from Regina, via Craven and Humboldt, to Prince Albert.

New Westminster, B.C.—The members of the council have under consideration plans submitted them by the C.N.R. for an entrance to and passage through the city.

St. John, N.B.—The St. John Railway Company will have its extension to Kane's Corner, near East St. John, in operation this month. A further agreement has been made between the company and the city council to extend the line from Kane's Corner along the Marsh Road, so as to complete the circuit for which the people lately petitioned. The entire circuit will be completed within sixty days.

Vancouver, B.C.—The excavation work on the Great Northern Railway cutting in Grandview will soon be completed. Ballasting for a double set of tracks has been practically finished. However, when the work in the cutting is complete, four lines will have been laid.

Victoria, B.C.—An important agreement, which will require parliamentary approval, has been signed on behalf of the New South Wales Government, and of Messrs. Norton, Griffiths & Company, for the construction of railways on the North Coast, including one which will shorten the route to Queensland, and another from Condobolin to Broken Hill, the latter place being an important mining centre which at present is only served by a railway from South Australia. The total cost of the railway scheme, it is estimated, will be $15,000,000. The lines are to be completed within two and a half years.

BRIDGES, ROADS AND PAVEMENTS.

Assiniboia, Sask.—Tenders will be received up till the 30th of September, 1913, for the construction of cement piers for a bridge over Sturgeon Creek. Plans and specifications may be obtained from Frank Ness, Clerk of the Municipality.

+—Chambly Canal, Ont.—The Dominion Government has awarded the HAMILTON BRIDGE COMPANY the contract for the construction of a steel bridge. The contract price is $2,450.

+—Dundas, Ont.—The town council has awarded the HYLAND CONSTRUCTION CO., Belleville, the contract for the construction of a bridge. The contract price is $5,000.

Halifax, N.S.—Tenders will be received up till the 30th of September, 1913, for the construction of a number of bridges and culverts in the County of Halifax. Plans and specifications may be obtained from Department of Public Works and Mines, Halifax. E. H. Armstrong, Commissioner Public Works.

London, Ont.—Judging from the tenders for the steel superstructure of the Wharncliffe road bridge, received by the board of works, the construction for the connecting link between West and South London will exceed the $25,000 appropriation voted to the work by the citizens. The lowest tender was that of the Hamilton Bridge Company, for $18,751.50. This, with the contract for the concrete work let some time ago, will bring the cost to $25,192, or $92 above the appropriation without providing for any extras. These extras will likely run the bridge cost up another $1,000.

▲—Ottawa, Ont.—Tenders will be received up till the 2nd of October, 1913, for the construction of asphalt pavements. Plans and specifications may be obtained from Arch. Currie, city engineer.

South Vancouver, B.C.—Construction is being carried on night and day on the pavement being laid on Kingsway Road, a stretch of miles of asphalt, bitulithic, and granitoid highway which will link the cities of Vancouver and New Westminster, for which formal opening ceremonies are being considered. When completed South Vancouver and Burnaby will have a road equal in magnificence to any highway in America.

Sturgeon Creek, Sask.—Tenders will be received up till September 30th, 1913, for the construction of two cement piers for a bridge over Sturgeon Creek on Saskatchewan Avenue, and also for a steel bridge at said point. Plans and specifications may be obtained from the engineer's office, municipal office, St. Charles. Frank Ness, clerk rural municipality Assiniboia.

70 % saving in joints

can be effected by using MANNESMANN TUBES, as they can be supplied in lengths up to forty feet. This means a reduction of from sixty to seventy per cent. in number of joints, jointing material and labor. Not only is actual money saved but safety is increased as there are proportionately fewer possible points of leakage. The total net cost of Mannesmann Tubes, when laid, is very low on account of the saving in joints and the speed with which the mains can be laid.

ASK FOR OUR BOOKLETS

Mannesmann Tube Co.

51 Victoria Square **Montreal** Limited

+—**St. Francis De Sales, Que.**—The town council has awarded M. J. STACK & CO. the contract for the construction of macadam pavements.

+—**St. John, N.B.**—The city council has awarded MR. MICHAEL GEORGE the contract for the construction pavement of concrete base with bitulithic surface on Owen Street, between Germain and Charlotte Streets. The contract price is $5,703.

Toronto, Ont.—The Works Commissioner has recommended that a treated wood block pavement be laid down on Teraulay Street, from Queen to Agnes Streets, at a cost of $30,000.

Toronto, Ont.—The Board of Railway Commissioners have approved of the plans of the Bloor Street viaduct with the alteration of one arch.

LIGHT, HEAT AND POWER.

Fort William, Ont.—One outcome of the official discovery that Fort William is paying more than Port Arthur for her supply of electrical energy from the Kaministiquia Power Company is that the mayor, City Manager McCulloch and Utilities Manager A. L. Farquharson have been empowered to take the matter up with the Kaministiquia Power Company at once, and at the same time to request the Hydro-Electric Commission of Ontario to submit estimates on the price at which they will be prepared to deliver one block of one thousand horsepower for one year and another block of one thousand horsepower for four years—making five thousand horsepower in all.

Kingston, Ont.—Mr. MacRow, manager of the Montreal Street quarry, has found the service of the thirty horsepower 550 volt alternating current motor which is used to operate one of the crushers, so much to his satisfaction, that he is negotiating with the Utilities' Department for the installation of a forty horsepower motor to operate another crusher, and also of an air-compressor to run the drills and hoisting apparatus. Mr. MacRow has also the intention of placing another motor in another quarry, a short distance to the north of the one mentioned.

Kingston, Ont.—The utilities committee of the City Council has been charged to take up again the matter of securing cheap power from the Hydro-Electric Commission.

Medicine Hat, Alta.—The city council are planning the expenditure of $250,000 to build another large addition to the present power plant and install electrical generating machinery to furnish 2,500 kilowatts of power. The old plant is at present furnishing about 450 kilowatts, and the new plant, which will be running within a few weeks, has a capacity of another 1,500 kilowatts. Practically all the power that can be turned out by the new and the old plants has been spoken for, and it will not be very long before the demand will be in excess of the supply. It is this realization that is causing the city fathers to turn their attention towards caring for the ensuing years.

Moose Jaw, Sask.—The date of installation of the 1,500 K.W. generator, the contract for which was let to Williams & Robinson, Rugby, Eng., in April last, to be in place and in operation by October 15th, has been projected to November 15th at the earliest.

+—**Ottawa, Ont.**—The contract has been let to the CANADIAN CRACKER WHEELER CO., of St. Catharines, Ont., for motors and electric apparatus for the Grand Trunk Pacific shops, Transcona, at the estimate of $26,500.

Portage la Prairie, Man.—Mr. E. J. Chamberlain, representing the Great Falls Company, has made a proposition to bring power to Portage upon the same conditions as the offer of three years ago, which at that time was futile. Recently Portage la Prairie has been endeavouring to come to an agreement with the city of Winnipeg officials concerning the bringing to Portage of power from Winnipeg.

▲—**Regina, Sask.**—Tenders will be received up till the 25th of October, 1913, for supplying equipment for powerhouse. Specifications may be obtained from E. W. Bull, Superintendent of Light, Heat and Power Department.

Regina, Sask.—Tenders will be received up till September 25, for plumbing, heating, and ventilation of the new wing, Regina General Hospital, and also for the Isolation Hospital. Plans and specifications may be obtained from N. R. Darrach, architect, Regina.

+—**Toronto, Ont.**—An agreement has been closed between Sir William Mackenzie and the Baltimore Utilities Company, to furnish the latter with 46,000 horsepower of Canadian electricity, the power to be delivered at the international line by the Electrical Development Company of Ontario, which has its plant at the Falls, to the Canadian-American Power Corporation. By that company it will be distributed. The contract is held by MESSRS. BERTRAM, GRISCOM & CO., of New York, who propose to capitalize at $3,000,000.

Toronto, Ont.—Sir William Mackenzie has just closed an important agreement with the Baltimore Utilities, by which he will sell them 46,000 horsepower of Canadian electricity. The power is to be delivered at the International line by the Electrical Development Company of Ontario, which has its plant at the Falls, to the Canadian-American Power Corporation, by which company it will be distributed. Some idea of the importance of the contract effected by Sir William may be gathered from the fact that the Toronto Street Railway uses only 40,000 horsepower.

Windsor, Ont.—At a recent meeting of the Detroit Common Council a communication was presented by Mayor Marx from Mayor Clay, of this city, inquiring as to whether Detroit was prepared to enter into a contract to purchase hydro-electric power from the city of Windsor, providing a rate was quoted lower than the current is now being produced in Detroit. The Common Council discussed the matter at considerable length and will send a definite report to Mayor Clay shortly.

GARBAGE, SEWAGE AND WATER.

+—**Fort William, Ont.**—The city council has awarded the CANADA IRON CORPORATION the contract for supplying the sixteen inch and special pipe. The contract price was $35 per ton for the 16-inch and $60 a ton for the special.

+—**Fort William, Ont.**—MR. RAY R. KNIGHT, city engineer, will lay the pipe on Island Two and across the Mission River. The lowest tender from a contractor for laying sixteen inch pipe was 59 cents, while the city engineer's tender was for 55 cents; the lowest contractor's tender for laying eighteen inch pipe was 68 cents, the city engineer's, 65 cents. The lowest contractor's tender for laying the pipe across the Mission was $5,753 and they ran as high as $14,000, while the city engineer's tender was for $5,753.

+—**Fort William, Ont.**—The contract for supplying the 6-inch iron pipe in the last-mentioned item was let to the CANADA IRON CORPORATION at $35 per ton, and for the supply of special pipe at $60 per ton. The cleaning and grading of streets on the island is to be done by W. T. RANKIN for $1,735.

Hamilton, Ont.—During a recent discussion at the meeting of the Board of Control over the removal of sand from the vicinity of the filtering basins, Mayor Allan stated that he thought the basins should be done away with altogether. He considers them a detriment to the waterworks system rather than a benefit, as he contends that the water merely passes through them, and that by reason of the fact that decayed vegetable matter grows in them, there is some danger of contamination from this.

+—**Moncton, N.B.**—The City Council has awarded Messrs. GOVANG & LE BLANC the contract for extension to sewers. The contract prices are: 10-inch pipe sewer $1.06 per foot; 12-inch pipe $1.15 per foot. Daniel Gotro was the only other tenderer his prices being $1.15 per foot for 10-inch and $1.22 for 12-inch pipe.

Montreal, Que.—That Montreal's new $3,000,000 filtration plant regarding which there has been so much discussion this summer, is not large enough, and that within twelve months at the latest another $1,000,000 or more will have to be spent on the work in order that it may meet the requirements of the city, is a situation which officials of the city aqueduct department disclosed at the City Hall recently. That the matter is a serious one, and one which will have to be taken up without loss of time, is evident from the statement made public regarding the city's consumption of water, and the steps which are about to be taken to increase the pumping capacity.

OTTAWA, ONT.

Please let us have full particulars regarding STEEL PIPE advertised in The Canadian Engineer.

NAME.....

ADDRESS.....

New Glasgow, N.S.—The town council in New Glasgow is asking for bids up to September 30th for the construction of 2,050 lineal feet of 24-inch sewer, and 550 feet of 20-inch sewer. Included in this, there is about six thousand cubic yards of excavation in trenches from 3-feet to 26-feet in depth. Pipe may be of reinforced concrete instead of vitrified clay. D. F. McLeod, town engineer.

Ottawa, Ont.—City Engineer Currie has presented his report to the city with regard to a temporary water supply, and outlined three plans. The first scheme, of an all-land route, would cost $283,000 and would take sixteen or eighteen months to install. The second scheme would have cost about $190,000, and would take about ten months. In this scheme the present pumps at the sedimentation basin would be used to create a greater head and thus make it possible to have the pipe near the surface, thus effecting a saving in pipe and excavation. A surface line, with new pumps at the mouth of the intake, would cost about $163,000 and take about eight months to carry through, was the third scheme.

Ottawa, Ont.—Tenders will be received up till September 27th, for supplies in connection with 40-inch steel intake pipe. Plans and specifications may be obtained from Arch. Currie, City Engineer.

+—Port Arthur, Ont.—The city council has awarded the THUNDER BAY CONTRACTING COMPANY the contract for the erection of a pumping station. The contract price is $12,500.

+—Sarnia, Ont.—The Imperial Oil Company has awarded the SMART TURNER MACHINE CO., LIMITED, Hamilton, the contract for supplying a power rotary force pump.

▲—Toronto, Ont.—Tenders will be received up till October 4th, 1913, for the construction of a sewer on Wychwood Avenue, in the Township of York. Plans and specifications may be obtained from office of Frank Barber, C.E., 57 Adelaide Street East, Toronto. Frank Barber, Township Engineer.

+—Victoria, B.C.—Water Commissioner Rust made the following recommendations relative to the awarding of the contracts for the concrete and steel pipe line, steel trestles and telephone line. The bid of the GRAFF CONSTRUCTION COMPANY for the concrete pipe line at $308,160 was recommended; that of the MACDONALD, GODSON COMPANY for steel pipe at $444,998, and the bid of F. H. FOLSOM for $8,625 for the telephone line. In connection with the steel trestles the bid of the CANADIAN NORTHWEST STEEL COMPANY at $24,808 was the lowest, but this price does not include erection. The GRAFF CONSTRUCTION COMPANY submitted a proposal to erect concrete structures in the place of steel for $40,000, but made this offer conditional upon their being awarded the contract for the concrete pipe line, and the city's consulting engineer, Mr. Wynn Meredith, recommended that the offer be accepted, provided the company's bid for the concrete pipe line is accepted. In connection with the steel pipe line the bid of MESSRS. JONES & RANT was lowest at $398,263, but it was based upon a percentage basis—that is, the city was to pay the cost and the company would supervise the work for a certain percentage cost. The bid was deemed irregular, and Mr. Meredith recommended the next lowest, that of the MACDONALD, GODSON COMPANY.

Victoria, B.C.—The City Council have decided to submit a by-law to the ratepayers to authorize the expenditure of an additional $1,500,000 to complete the Sooke Lake Waterworks scheme.

Winnipeg, Man.—The city has recently had a report on a new system of waterworks by Rudolph Hering and Jas H. Furetes, of New York, and Frederick P. Stearns, of Boston, who have reported favorably on bringing water 95 miles from a lake by gravity in a concrete pipe to carry 85 million Imperial gallons per 24 hours, at a cost of $13,045,600. Legislation authorizing this work to be carried on has been obtained and the city council at its meeting on the 8th instant, unanimously passed the appropriation and sent it to the people for ratification by election of the taxpayers, and it is to be voted on on October first. There is practically no doubt but that it will be ratified and the work of completing the surveys and plans will at once go on and contracts will probably be let during the coming winter. The months of September, October and November are the best months of the year in which to examine the country along the line of the pipe, and it would be better for contractors intending to tender to make an examination of the ground during these months, as it is somewhat difficult of access in the winter and early spring. Advertisements for bids will appear in the leading papers of America and Europe after the appropriation has been authorized by the people. The above statement is made now so that parties wishing to examine the ground may know the present standing of the matter. There is practically no doubt that this work will go on and the contracts be let during the coming winter.

Winnipeg, Man.—The Trades and Labor Council have passed a resolution unanimously adopting and endorsing the Shoal Lake waterworks scheme, and recommending all labor men entitled to vote on money by-laws to exercise their franchises for the furthering of the proposition.

INDUSTRIAL WORKS.

Athabasca, Alta.—A delegation from the local board of trade has waited upon the Premier at Edmonton requesting that the Alberta and Great Waterways be constructed from Athabasca, and that work be started as early as possible.

Brantford, Ont.—Instructions have been given to City Engineer Jones by the Waterworks Commissioners, to provide plans for the construction of a dyke across the waterworks property near the foot of West Mill Street, the low-lying lands between the canal and the river in the direction of Wilke's dam. The dyke will be about one-half mile wide.

+—Caledonia, Ont.—Messrs. McGregor and Co., have awarded to THE SMART-TURNER MACHINE CO., Hamilton, Ont., the contract for one of their duplex pumps.

Fisher River, Man.—Tenders will be received up till noon of the 15th of October next, for the construction of a residence on the Agency ground in the Peguis Indian Reserve at Fisher River, Man., in Section 17, Tp. 17, R. 1, west of the 1st Meridian. Plans and specifications may be seen at the Indian Offices at Winnipeg, Selkirk, and Portage la Prairie, and at the post-offices at Teulon, Arborg, and Stonewall, or may be obtained upon application to the Department at Ottawa. J. D. McLean, Assistant Deputy and Secretary.

Fort William, Ont.—Senator N. Curry, president of the Canadian Car and Foundry Company, has stated construction on the plant at West Fort William is progressing favorably, and that the company's expectation is to commence business about the end of the year.

▲—Galt, Ont.—Tenders will be received up till the 27th of September, 1913, for the construction of river walls. Plans and specifications may be seen at the office of the town clerk, Galt, Ont.

▲—Halifax, N.S.—Tenders will be received up till the 15th of October, 1913, for the construction of about 6,500 lineal feet of quay wall, foundations for buildings, sewers, dredging of harbor, and filling reclaimed areas. Plans and specifications may be obtained from Department of Railways and Canals, Ottawa. L. K. Jones, Assistant Deputy-Minister and Seretary.

+—Island River, B.C.—The Dominion Government has awarded W. J. PENPORE CO., LIMITED, the contract for dredging required here.

Little Dipper Harbor, N.B.—Tenders will be received up till the 15th of October, 1913, for the construction of a breakwater. Plans and specifications may be obtained from Mr. E. F. Goodspeed, District Engineer, St. John, and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Mace's Bay, N.B.—Tenders will be received up till the 14th of October, 1913, for the construction of a breakwater. Plans and specifications may be obtained from Mr. F. G. Goodspeed, District Engineer, St. John and the Department of Public Works, Ottawa. R. C. Desrochers, Secretary.

McAuley's Shore, P.E.I.—Tenders will be received up till the 7th of October, 1913, for the construction of a wharf. Plans and specifications may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Newcastle, Ont.—Tenders will be received up till the 15th of October, 1913, for the repairs to eastern pier here. Plans and specifications may be obtained from J. G. Sing, District Engineer, Toronto, and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

▲—**Ottawa, Ont.**—Tenders will be received up till the 15th of October, 1913, for section No. 2 of the Welland ship Canal. Plans and specifications may be obtained from the Department of Railways and Canals, Ottawa. L. K. Jones, Secretary.

+—**Quebec, Que.**—The Transcontinental Railway Commission has awarded Contractor GOSSELIN, of Levis, the contract for the construction of the workshops of the railway at St. Malo. The contract price is $1,500,000.

Roy's Beach, B.C.—Tenders will be received up till the 9th of October, 1913, for the construction of a wharf. Plans and specifications may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

+—**Rustico, P.E.I.**—The Dominion Government has awarded MR. V. T. BERTRAM, Toronto, the contract for the dredging required here.

+—**St. John, N.B.**—The city council has awarded R. ROBERT & SONS the contract for the construction of a ferry wharf. The contract price is $9,800.

St. John, N.B.—A powerful new dredge, the "Don Frederico," has arrived at Halifax. She is a big ladder dredge from Scotland, and when completely equipped, will be used at the harbor mouth on the work formerly carried on by the NORTON-GRIFFITHS DREDGING CO.

+—**St. Vital, Man.**—The Provincial Government has awarded the WINNIPEG ENGINEERING CO. the contract for the construction of an underground feeder system. The contract price is $40,000.

Vancouver, B.C.—Tenders will be received up till the 27th of September, 1913, for oil burning installation in dredge "Ajax." Plans and specifications may be obtained from C. C. Warsfield, Esq., New Westminster, and the Department of Public Works, Vancouver. J. L. Nelson, Superintendent of Dredges.

Vancouver, B.C.—The steel-work upon the warehouses for the new Great Northern dock on Burrard Inlet, a short distance west of the British Columbia Sugar Refinery, are now well advanced, and the filling-in of the section of the dock between the two piers is almost complete.

+—**Windsor, Ont.**—The Cleveland Foundry Company, Cleveland, will locate a plant in this city. It will cost $200,000.

MISCELLANEOUS.

Bassano, Alta.—In spite of the desire of the town to delay the closing of the dam on account of the waterworks intake not yet being completed, the C.P.R. have announced that the gates for the $6,000,000 irrigation dam at Bassano will be tested not later than October 1st.

Berlin, Ont.—Berlin has disposed of all the debentures issued by the city council this year, amounting to $281,000, a portion bearing 5½ per cent. interest, and some 6 per cent. Of the debentures, $60,000 was raised for extensions to the electric and gas plants, $30,700 for double-tracking the street railway, $50,000 for extensions to the waterworks plant, $87,500 for new trunk sewer, $11,000 for new park lands, and the balance for local improvements constructed last year.

Bogota, Colombia.—The control of a petroleum field of over 1,200 square miles in extent, in Colombia, has been secured by the Colombian Syndicate, Limited, of Canada.

+—**Calgary, Alta.**—The Ranchmen's Club has awarded MESSRS THOMAS, JAMIESON & McKENZIE, the contract for the erection of a club building. The contract price is $20,000.

Fort William, Ont.—Tenders will be received up till the 14th of October, 1913, for the erection of an examining warehouse. Plans and specifications may be obtained from Mr. H. E. Mathews, Winnipeg; W. P. Merrick, District Engineer, Fort William, and the Department of Public Works, Ottawa. R. C. Desrochers, secretary.

Fredericton, N.B.—The plans of the new freight sheds to be erected by the Intercolonial Railway, and for which tenders are being invited up to September 25th, have been received in Fredericton.

Guelph, Ont.—The students, ex-students, and friends of the Ontario Agricultural College intend erecting a hockey rink on the college grounds this season, and every effort will be made to have it completed for use this winter.

+—**Hamilton, Ont.**—The Canadian Westinghouse Company has awarded MESSRS. H. G. CHRISTMAN & SON the contract for the erection of a new foundry. The contract price is $150,000.

Harriston, Ont.—The board of trade and town council have been successful to such an extent in their negotiations with manufacturing houses for the establishment of plants in Harriston that building operations may soon be under way on the Livingstone property.

London, Ont.—The Colonial Commerce Exchange will establish a business institute, club, and hotel for the centralization of the trade coming overseas at London. Should the Earl Grey scheme fail, the company propose securing the Aldwych site for their construction.

+—**Montreal, Que.**—The city council has awarded MR. JOS. MONETTE the contract for the erection of a fire station. The contract price is $65,100.

+—**Montreal, Que.**—The Harbor Commission has awarded the RAYMOND CONCRETE PILE COMPANY, Montreal, the contract for driving approximately 1,010 Raymond concrete piles.

+—**Moose Jaw, Sask.**—The International Linseed Oil Co. has awarded the CLARK CONSTRUCTION COMPANY of Chicago the contract for the erection of their plant.

+—**New Westminster, B.C.**—MR. JOHN CALBICK has been awarded the contract for building the additions to the Provincial Exhibition buildings. The contract price is $17,500.

North Vancouver, B.C.—A largely signed petition has been put before the city council of Vancouver, asking that Sutherland Avenue, from Lynn Valley Road, north to Twenty-Fifth Street, and thence west along that boulevard to Lonsdale Avenue, be graded and macadamized with a view to forming a highway of good roads between Lynn Valley and North Lonsdale as well as to providing a circular driveway within the city.

+—**Ottawa, Ont.**—MR. T. C. JAMES has been awarded the contract for the erection of a business block. The contract price is $100,000.

+—**Ottawa, Ont.**—The contract has been awarded to the firm of CROCKETT AND SHARLE, Fort William, Ont., for the construction of the Customs building to be erected on Mackenzie Avenue, Ottawa, the tender price being $993,000.

Ottawa, Ont.—It is expected that tenders will be called for shortly for the construction of Vancouver drill hall and immigration building.

+—**Port Arthur, Ont.**—The Great Lakes Dredging Company have awarded THE SMART-TURNER MACHINE CO., of Hamilton, Ont., the contract for one of their duplex pumps.

+—**Regina, Sask.**—The Grand Trunk Railway has awarded the RAYMOND CONCRETE PILE COMPANY, Montreal, the contract for driving approximately 1,000 Raymond concrete piles for the Qu'Appelle Hotel.

St. John, N.B.—Hon. John E. Wilson is agitating in the Provincial Government the need of a provincial building in this city, suitable for various needs of the province, such as the Equity Court, the Immigration Office, the Government's own rooms, etc.

St. Thomas, Ont.—The Union Label Stores Co. plan to erect a branch store in St. Thomas for the sale of their goods. Their plan and principles of the company have been endorsed by Union Labor representatives of the city.

+—**Trenton, Ont.**—The contract has been awarded ROGER-MILLER & SONS, CO., for putting in forty pairs of gates between Trenton and Rice Lake on the Trenton Canals, a work which will require one and half-years for its completion.

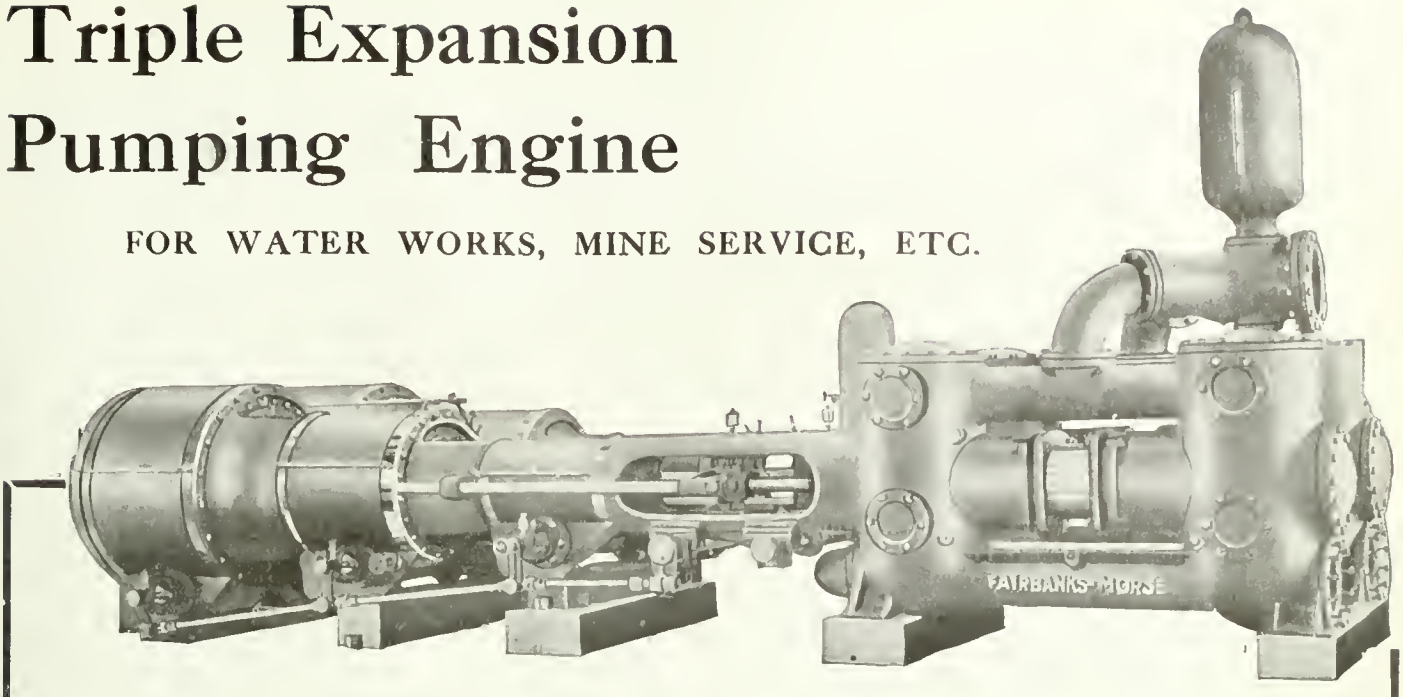
Vancouver, B.C.—The announcement was made by A. B. Godfrey, district superintendent of the British Columbia Telephone Company, that the work of replacing the old style telephone wires on the down-town streets of Trail with modern lead cable will soon be completed.

Vancouver, B.C.—Tenders will be received up till the 29th of September, 1913, for the erection of North Vancouver school. Plans and specifications may be obtained from the Department of Public Works, Victoria. J. E. Griffith, Public Works Engineer.

Vancouver, B.C.—The board of works committee have decided not to retract from its request to the British Colum-

Triple Expansion Pumping Engine

FOR WATER WORKS, MINE SERVICE, ETC.



The Fairbanks-Morse Triple Expansion Duplex Outside Centre Packed Plunger Pumping Engine shown here is very economical in the consumption of steam. The economy of operation makes this Pump preferable to all others in many situations.

The steam end is fitted with semi-rotative valves. The plungers being externally packed are always in sight and any leakage can be at once detected. All parts are easy of access. The stuffing boxes are large and deep, so that ample allowance of packing may be used.

This type of pump is heavily proportioned throughout in order to meet the demands of heavy service. It is designed to give long and satisfactory service at a minimum cost. It has a 24-inch stroke and a capacity of 2,500,000 gallons per 24 hours.

Departmentalising a Great Business

The marketing of one article is a very simple problem. As the number and variety of the products you sell increase, the complexity of your merchandising problem grows.

Our business has grown in the last dozen years from a comparatively few products into an enormous number of lines. This tremendous growth has necessitated the organizing of our business along departmental lines with able, efficient men at the heads of the various departments.

As organized now we can serve the mechanical field better than any house in Canada. In addition to being manufacturers, we are literally a large "departmental house for machinery and mechanical goods." This bringing together of a vast number of lines and classifying them according to departments is the kind of combination in industry that makes for efficiency, economy and better service.

It is just as great a convenience to Engineers, Contractors and Builders to be able to get their supplies from one House as it is to the general public to shop in a large, modern department store. In dealing with us you can get what you want "under one roof." Write, phone or call.

bia Electric Railway to lay permanent tracks on Hastings Street from Nanaimo to Renfrew Street, and have recommended that the company be required to proceed with the work this year.

Vancouver, B.C.—The Coca Cola Co. contemplate the erection of a plant in this city for the manufacture of their product. At present its location in either Winnipeg or Vancouver is still under consideration.

Vancouver, B.C.—Information has been received that the Union Steamship Company, of New Zealand, propose to build another steamer for service on the Pacific similar to the Palace Niagara.

+—Victoria, B.C.—Mr. C. E. Watkins has awarded MESSRS. FULTON BROS. the contract for the erection of his apartment block. The contract price is $45,000.

Victoria, B.C.—It is said that plans for a new east wing to the courthouse corresponding to the west wing, are being prepared by the provincial architects of Victoria, the cost of which will amount to several hundred thousand dollars.

+—West Toronto, Ont.—The Swift Canadian Co. have awarded THE SMART-TURNER MACHINE CO., Hamilton, Ont., the contract for a duplex pump.

Winnipeg, Man.—Tenders will be received up till the 30th of September, 1913, for out-buildings Portage la Prairie boarding school. Plans and specifications may be obtained from the Department of Indian Affairs, Ottawa. J. D. McLean, secretary.

CURRENT NEWS.

Berlin, Germany.—The first congress of the German Society organized to deal with the question of the efficacy of the divining rod and its scientific value in discovering and locating deposits of potash, coal, subterranean caves and water streams, met at Halle on September 19th, and was attended by delegates from foreign countries. The members of the congress include the President of the Province of Saxony and other provincial, municipal, and university officials.

Fort William, Ont.—Engineers of the Lighthouse Bureau, Washington, have finished installing a new apparatus at Whitefish Point, Lake Superior, and now mariners will be guided by one of the largest lights in the world. It has 3,000,000 candle-power. The increased intensity was obtained by changing from oil to incandescent oil vapor. The new light is the largest on the Great Lakes. Up to this time the Split Rock and White Shoal lights have been the most powerful, 1,200,000 candle-power. They can be seen 25 to 50 miles, but the new light can be seen 75 miles, except during storms.

Hamilton, Ont.—The Hon. Robert Rogers, minister of public works, has inspected the local harbor in order to ascertain what the local harbor commissioners desire to have accomplished; mainly the necessity of developing Stipe's inlet for wharf and harbor purposes for the benefit of east end manufacturers.

Lethbridge, Alta.—The Richardson Automatic Scale Co., of Passaic, N.J., have found it desirable to establish a Canadian branch of their firm at Lethbridge. Orders from the Ellison Milling Company of Lethbridge, Alberta Farmers' Co-operative Elevator Company and the Ogilvie Milling Company, of Medicine Hat, are awaiting manufacture at Lethbridge.

New Westminster, B.C.—Another unit in the equipment being installed by the city for the work in connection with harbor improvements in nearing completion. Carpenters are now engaged in housing in the machinery on the big Lidgerwood derrick, which will be used in unloading the barges of sand and silt and depositing it behind the quay walls along Front Street. This machinery will be operated by electricity, 6 360-kilowatt transformers having been installed and connected with the power cables of the British Columbia Electric Railway. The dredge John A. Lee is now receiving the finishing touches, all the machinery being in place, and oil burners are being placed under the boilers. The dredge will be ready in about a week. The city tug "Haro" has passed inspection, and is ready for active service. Work is progressing rapidly on the dock and already eight bents of poles are in place, capped and ready for sheet piling.

Ottawa, Ont.—A commission of citizens who have given special attention to city planning, has been selected by the Dominion Government to draw up a plan for the systematic development of the capital district.

TRADE ENQUIRIES.

The following inquiries relating to Canadian trade have been received. 993.—A French concern would like to get in communication with Canadian manufacturers or agents willing to undertake the construction of a new patent mechanic pump in Canada. 1002.—A French concern exporting Portland cement would like to open relations with Canadian buyers. 1003.—A firm in Berlin, Germany, largely interested in calcium carbide and its products, desires to hear from producers in Canada able to undertake supplies to Germany. 1004.—A well-established firm in Frankfurt-on-Main, Germany, is open to represent Canadian works manufacturing the above articles. Highest references given. 1006.—A prominent firm in Vienna, Austria, is open to represent Canadian mining companies producing asbestos, talc, etc., for which there is a large market in Austria. The firm is well recommended. 1030.—A German company desires the addresses of Canadian firms who would be interested in purchasing pumps for waste and refuse water, etc. 1033.—A gentleman in Marseilles, interested in the import and export trade with various countries, desires to represent Canadian exporters, as an agent or on commission, in all commodities; machinery, foodstuffs, manufactures, provisions, grain, etc. He also has business relations in Algeria, Tunis, Morocco, Spain, Italy and Egypt. 1038.—An Austrian merchant is seeking supplies of corundum and desires to get in touch with Canadian producers and shippers. 1043.—A very important French concern manufacturing all kinds of motor vehicles would like to appoint several agents for the different provinces of Canada. The names of the firms making these inquiries with their addresses may be obtained upon application to:—The Inquiries Branch, the Department of Trade and Commerce, Ottawa, or the Secretary of the Canadian Manufacturers' Association, Toronto, or the Secretary of the Board of Trade at London, Toronto, Brandon, Halifax, Montreal, St. John, Sherbrooke, Vancouver, Victoria, Winnipeg, Calgary, and Chambre de Commerce du District du Montreal.

Sewers last indefinitely—or rather they should do so. They will last indefinitely if laid with MIMICO PIPE.

Round Pipe and Square D lings

To be permanent a sewer should be built of a good material that can be handled and inspected simply and surely MIMICO PIPE is finished completely and perfectly at the factory and when delivered can be easily tested. It is far preferable to any material made of several ingredients any one of which may cause failure by being defective, and the mixing of which requires most careful, skilled attention.

NOW READY

Text-Book on Highway Engineering

By Arthur H. Blanchard, C.E., A.M., Professor of Highway Engineering in Columbia University, New York City, and Henry B. Drowne, C. E., Instructor in Highway Engineering in Columbia University, New York City. 8vo, xiii+762 pages, 234 figures and 4 charts. Cloth, $4.50 net.

This book has been made mainly from the standpoint of the instructor and the student; giving, first, the logical order and arrangement of the subject-matter, and second, sufficient detail to thoroughly acquaint the student with the principles and practice of modern highway engineering.

FOURTH EDITION, Revised and Enlarged

Text-Book on Roads and Pavements

By Frederick P. Spalding, Professor of Civil Engineering, University of Missouri. 12mo, xii+408 pages, 51 figures. Cloth, $2.00 net.

In this edition the author has practically rewritten the entire book, new chapters being added on Bituminous, Macadam and Concrete Pavements, and modifications being made of the chapters on brick, asphalt and wood pavements.

SECOND EDITION, Revised and Enlarged

Street Pavements and Paving Materials

By George W. Tillson, C.E. 8vo, xii+651 pages, 97 figures. Cloth, $4.00 net.

A manual for city pavements; the methods and materials of their construction. For the use of students, engineers, and city officials.

SECOND EDITION, Enlarged

A Treatise on Roads and Pavements

By Ira Osborn Baker, C. E., D.Eng'g., Professor of Civil Engineering, University of Illinois. 8vo, xi+698 pages, 171 figures, 72 tables. Cloth, $5.00.

The purpose of the new edition of this volume was to add a chapter on Automobile Roads and Concrete Pavements. This is due to the remarkable increase in the number and power of automobiles in the past decade, which has led to the development of new forms of road surfaces designed specially to resist motor traffic.

TENDERS CALLED FOR

NOTICE TO CONTRACTORS.

ASPHALT PAVEMENTS.

Sealed tenders addressed to the Chairman and Members of the Board of Control, City Hall, Ottawa, will be received by the Secretary of the Board of Control, up to 4 p.m. Thursday afternoon, October 2nd, 1913, for the construction of asphalt pavements on:—

Clarence Street, from King Edward Avenue to Chapel Street.

O'Connor Street, from Queen Street to Laurier Avenue.

Any tender received after the above stated time will be declared informal.

Specifications and full particulars may be obtained on application at the City Engineer's office, City Hall, Ottawa.

The Corporation does not bind itself to accept the lowest or any tender.

ARCH. CURRIE,
City Engineer.

Ottawa, September 23rd, 1913.

TOWN OF GALT.

TENDERS FOR RIVER WALLS.

Sealed alternative tenders addressed to the Town Clerk, Galt, Ontario, and endorsed, "Tenders for River Walls," will be received until noon of **Saturday, September 27th, 1913,** for the construction of:—

(1) A concrete retaining wall, reinforced, 680 feet in length, approximately, along the westerly bank of the Grand River, from Main Street to Blair Road.

(2) A gravity retaining wall, reinforced, 680 feet in length, approximately, along the westerly bank of the Grand River, from Main Street to Blair Road.

Plans and specifications may be seen at the office of the Town Clerk, Galt, Ontario, after Friday, September 19th, 1913.

Each tender must be accompanied by a marked cheque, payable to the order of the Town of Galt for 5 per cent. of the amount of the tender. The corporation of Galt does not bind itself to accept any or the lowest tender.

CHAS. D. CAMPBELL,
Galt, Ont., September 17th, 1913. Town Clerk.

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

CANADIAN GOVERNMENT RAILWAYS.

Halifax Ocean Terminals Railway, Halifax, N.S.

Sealed tenders addressed to the undersigned and endorsed "Tender for docks, First Unit, Contract No. 3, Halifax Ocean Terminal," will be received at this office until twelve o'clock noon, Wednesday, the fifteenth day of October, 1913, for the construction of about 6,500 lineal feet of quay wall, foundations for buildings, sewers, dredging of harbor to a depth of 45 feet at low water, and filling reclaimed areas.

Plans and specifications and form of tender may be seen and full information obtained at the office of the General Manager, Moncton, N.B., at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Superintending Engineer, Halifax, N.S.

The right is reserved to reject any or all tenders.

By order, L. K. JONES,
Assistant Deputy-Minister and Secretary.
Department of Railways and Canals,
Ottawa, September 2nd, 1913.

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

WELLAND SHIP CANAL.

SECTION No. 2.

NOTICE TO CONTRACTORS.

Sealed Tenders, addressed to the undersigned and marked "Tender for Section No. 2, Welland Ship Canal," will be received at this office until 12 o'clock noon on **Wednesday, October 15th, 1913.**

Plans, specifications and form of contract to be entered into can be seen on or after this date at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Engineer in Charge, St. Catharines, Ontario.

Copies of plans and specifications may be obtained from the Department on the payment of the sum of fifty dollars. To bona fide tenderers this amount will be refunded upon the return of the above in good condition.

Parties tendering will be required to accept the fair wages schedule prepared or to be prepared by the Department of Labor, which schedule will form part of the contract.

Contractors are requested to bear in mind that tenders will not be considered unless made strictly in accordance with the printed forms, and in the case of firms, unless there are attached the actual signature, the nature of the occupation, and place of residence of each member of the firm.

An accepted bank cheque on a chartered bank of Canada for the sum of $150,000.00 made payable to the order of the Minister of Railways and Canals, must accompany each tender, which sum will be forfeited if the party tendering declines entering into contract for the work, at the rates stated in the offer submitted.

The cheque thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque of the successful tenderer will be held as security, or part security, for the due fulfilment of the contract to be entered into.

The lowest or any tender not necessarily accepted.

By order,
L. K. JONES,
Asst. Deputy Minister and Secretary.
Department of Railways and Canals,
Ottawa, 22nd September, 1913.

Newspapers inserting this advertisement without authority from the Department will not be paid for it.—48056.

TENDERS FOR CONSTRUCTION OF SEWER.

Sealed tenders plainly marked as to contents will be received at the office of the undersigned up to noon on Saturday, October 4th, 1913, for the construction of a sewer on Wychwood Avenue, in the Township of York.

Plans and specifications and all information may be obtained at the office of Frank Barber, C.E., 57 Adelaide Street East, Toronto. The lowest or any tender not necessarily accepted.

FRANK BARBER,
Township Engineer.

Toronto, September 24th, 1913.

MEXICAN EAGLE ASPHALT

TRADE MARK

East Main Street, Hamilton, Ont., paved with Mexican Eagle Asphalt.

Mexican Eagle Asphalt is the purest asphalt on the market. It is also a favorite among city engineers for its high cementing value and ductility. That means that sheet asphalt pavements constructed with Mexican Eagle Asphalt take first place among permanent pavements. Because there is no doubt but that sheet asphalt is in general the most satisfactory pavement. Read the experiences of a few Canadian cities:

OTTAWA, ONT.

Five-sixths of the thirty miles of permanent pavement in Ottawa is sheet asphalt. The principal business and residential streets are paved with it. The city engineer's department says that, if properly constructed, asphalt has been found to be about the best pavement they can have. Ottawa has a great many streets constructed with Mexican Eagle Asphalt.

WINNIPEG, MAN.

Winnipeg has laid eighty-one miles of sheet asphalt since 897, for all kinds of traffic. City Engineer Ruttan installed the first municipal asphalt paving plant in Canada. In their experience the asphalt has worn uniformly and has been extremely satisfactory, particularly the pavements constructed with Mexican Eagle Asphalt.

VICTORIA, B.C.

Sheet asphalt is pr ctically the only kind of pavement laid in Victoria, only four out of the forty-eight miles of permanent paving being of any other type. It has been Victoria's experience that no repairs at all are necessary in the first five years, and extensive repairs are necessary only after ten years' wear.

TORONTO, ONT.

As in most cities, asphalt predominates in Toronto, over 157 miles of sheet asphalt pavement having been laid since 1887. The average cost of maintenance per square yard during ten years has been only slightly over five cents a year. For both residential and business streets it is the principal pavement. One of the many Toronto streets that are laid with Mexican Eagle Asphalt was illustrated in the Sept. 11th issue of The Canadian Engineer.

LONDON, ONT.

The city engineer of London says that asphalt pavements in London that have been down nine years are in good shape and will likely be so for another four or five years. Of less than nine miles of pavement in London, over five miles are sheet asphalt.

HAMILTON, ONT.

Thousands of tons of Mexican Eagle Asphalt have been sed in Hamilton during the past five years. Asphalt greatly predominates there, two-thirds of the thirty miles of permanent paving being sheet asphalt. The principal business streets are paved with it. The average cost of maintenance per square yard for the first five years has been two cents a year.

Tenders Called For

DEPARTMENT OF MILITIA AND DEFENCE.

Extension to Stables, Tete-de-Pont Barracks, Kingston, Ont.

NOTICE TO CONTRACTORS.

Sealed tenders, marked on the envelope, "Tender for Construction of extension to stables, Tete-de-Pont Barracks, Kingston," and addressed to the Director of Contracts, Department of Militia and Defence, Ottawa, will be received until noon, September 30 instant, for the construction of an extension to the stables at Tete-de-Pont Barracks, Kingston, Ont.

Specifications may be seen and full particulars obtained at the offices of the Officer Commanding the 3rd Division, Kingston, Ont., and the Director General of Engineer Services, Headquarters, Ottawa.

Tenders must be made on the form supplied by the Department of Militia and Defence, and accompanied by an accepted cheque on a Canadian Chartered Bank, for ten per cent. (10%) of the amount of the tender, payable to the order of the Honorable the Minister of Militia and Defence, which amount will be forfeited if the party tendering declines to enter into or fails to complete the contract in accordance with his tender.

The Department does not bind itself to accept the lowest or any tender.

EUGENE FISET, Deputy-Minister.

Ottawa, September 2, 1913.

GAS AND GASOLINE ENGINE, ten horsepower, Fairbanks-Morse; excellent condition; bargain. Can be seen in operation. Review Company, Bridgeburg, Ont.

COAST TO COAST.

Brandon, Man.—What with street paving, car-barns, rocmac, trips to the east to sell debentures and the resulting disputes in the city council chamber, a project for the real good of the city and the welfare of its inhabitants is, according to Alderman Shillinglaw, being ignored. This is the building of a large and up-to-date incinerator. A short time ago Alderman Shillinglaw outlined a proposition to the city fathers whereby the dangers of typhoid and other epidemic diseases would be very much lessened, if not entirely eliminated, and the question of the proper disposal of garbage and offal from the slaughter houses satisfactorily answered. This can only be done, in Mr. Shillinglaw's opinion, by means of a large incinerator, in which all refuse, garbage and germ-producing matter could be in a few minutes reduced to a harmless ash. The incinerator that the alderman would like to see in operation would cost about $40,000, and it would serve the requirements of Brandon for many years. Among the citizens generally the subject has not, as yet, received much attention, but there is no doubt that when the present strenuous times are past, the matter will be gone into more fully. The practical use, especially from a sanitary point of view, of the incinerator was most evident at the military camp at Sewell, where one of these important aids to sanitation was in constant operation behind every cook tent. The most noticeable feature at Sewell camp was the cleanliness of the lines and total absence of foul odors.

Victoria, B.C.—With the completion of the great dam which the Vancouver Island Power Company has been constructing for the past year at its Jordon River power plant, one of the largest works of its kind in Canada is now ready to fill its part in the development of power for the operation of commercial enterprises in the southern end of Vancouver Island. The dam, which is the highest of any in Canada, and has cost nearly three-quarters of a million, will provide storage capacity sufficient to assure an ample supply of water throughout the summer for the operation of the turbines. The necessity of additional storage capacity became imperative when the company undertook to raise the capacity of the power plant from 12,000 to 32,000 horse-power. The work of installing the additional units in the power house has been under way for some months. With this increase in power and the Brentwood Bay steam auxiliary plant of 6,000 horse-power in reserve, the company will have ample power to operate the lines of the British Columbia Electric Company, and meet the remarkable increase in the demand for power for industrial and commercial purposes. Mr. G. M. Tripp, mechanical superintendent of the company, went to Jordon River recently to make a thorough inspection of the new work.

A box of GROUND MICA in your MACHINE SHOP
will pay for itself in two weeks if used in tempering steel tools.
O'BRIEN & FOWLER
CUMMINGS BRIDGE - ONTARIO

PERMANENCE—

an ideal that is now attainable

THE superiority of concrete over all other materials for the building of permanent structures is now generally admitted.

The next step towards ideal construction, is to realize that for satisfactory concrete work, it is necessary to use a cement that is uniformly high-grade

CANADA Portland CEMENT

is the selection of the leading engineers, architects and contractors. Their experience has proved that in this brand they can obtain a certainty of success.

With concrete coming into more and more general use for the construction of buildings, bridges, viaducts and highways, it is vitally important that those in authority on such matters should select the best materials obtainable.

Use the cement that our best architects and engineers have selected for their most important undertakings. Select Canada Cement — it costs no more than any others.

PATENT NOTICE.—Any one desiring to obtain the invention covered by Canadian patent No. 135587, granted September 12th, 1911, to John Sorley, of Fielding, New Zealand, for composition for the destruction of insects, may do so upon application to the undersigned, who are prepared to supply all reasonable demands on the part of the public for the invention, and from whom full information may be obtained. Fetherstonhaugh & Smart, 53 Queen Street, Ottawa, Canada; Russel S. Smart, resident.

PATENT NOTICE.—Any one desiring to obtain the invention covered by Canadian patent No. 114335, granted on September 29th, 1908, to S. Vivian, for fluid flow controller, may do so upon application to the undersigned who are prepared to supply all reasonable demands on the part of the public for the invention and from whom full information may be obtained. Fetherstonhaugh & Smart, 53 Queen Street, Ottawa, Canada; Russel S. Smart, resident.

TAKE NOTICE that the undersigned are prepared to supply at a reasonable price the explosive described in Canadian Letters Patent No. 91254, issued on the 31st day of January, 1905, to Hans Von. Dahmen, or to grant anyone a license to have the same manufactured for him at a manufacturing establishment in the Dominion of Canada. They are also prepared to receive offers for the purchase of the patent or for licenses to manufacture under the same. Ridout and Maybee, 59 Yonge Street, Toronto, attorneys for Hans Von Dahmen.

PATENTS.

The following is a list of patents recently issued through the agency of Messrs. Ridout and Maybee, 59 Yonge Street, Toronto, from whom further particulars may be obtained:—

Canada.—Chas. H. de Ruset, lubrication of internal combustion motors; George J. Webb, devices for cleaning or removing obstructions in pipes, tubes and the like; Chas. H. de Ruset, control mechanism for internal combustion motors; Chas. H. de Ruset, internal combustion motors; Wm. E. Simpson and Howard Oviatt, furnaces for the direct production of iron and steel from iron ores; Ernest Colegate, the fastening or sealing of boxes, packets, wrappers and the like; Oswald Silberrad, perchlorate explosives; Jesse H. Tromanhauser, constructing cribs, sea-walls and the like.

Belgium.—B. R. Seabrook, improvements in differential railway axles; B. R. Seabrook, method of separating axle couplings; B. R. Seabrook, differential axles.

It has been decided to strengthen the foundations of the piers of the old Val Benoit bridge at Liège, Belgium, over which the international trains from Paris to Cologne cross the Meuse, by injecting cement under pressure into the underlying gravel of the river, so as to form a large monolithic mass at the foot of each pier.

SPIDERS ON THE PANAMA CANAL WORK.

Among the numerous workers who are contributing their little share to the construction of the Panama Canal is a number of spiders at Gorgona Shops. They are kept in the instrument room, and are carefully protected, because from their cocoons the instrument makers procure filament for use in the transits of the surveyors. The instrument repair men at Gorgona have been using the thread taken from the cocoon of a certain variety of spider that has been encouraged to multiply in the instrument shop for the past seven years to replace the platinum thread when it wears out. This use of the filament from the cocoon is not original on the Isthmus; indeed, it has been a common practice for many years.

It has been found that when the instruments so repaired are used early in the morning or during a rain the thread does not remain taut, because the instrument itself contracts. As soon as the instrument warms up, however, the spider web answers its purpose very well. In order that there may be no time of the day in which the transits may not be used, an order has been placed for platinum thread. As soon as it arrives on the Isthmus the use of the spider web will be discontinued, and the Canal force will be reduced by at least half a dozen more workers, for there are at least that many spiders spinning fibre at Gorgona Shops.

MARKET CONDITIONS

Montreal, September 20th, 1913

Bar Iron and Steel.—Trade is reported active. Bar iron, $2.10 per 100 pounds; best refined horseshoe, $2.35; forged iron, $2.25; mild steel, $2.20, sleigh shoe steel, $2.20 for 1 x ⅜ base; tire steel, $2.30 for 1 x ⅜ base, toe caulk steel, $3; machine steel, iron finish, $2.25.

Cement.—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal - $1.35 to $1.40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag Good bags re-purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight

Chain.—The market is quoted per 100 lbs. as follows:—¼-in., $5.65; 5/16-in., $4.70; ⅜-in., $4.00; 7/16-in., $3.65; ½-in., $3.45; 9/16-in., $3.45; ⅝-in., $3.35; ¾-in., $3.25; ⅞-in., $3.15; 1-in., $3.05.

Explosives and Accessories.—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1 and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4 ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12

Galvanized Iron.—The market is steady. Prices, basis, 28-gauge, are:—Queen's Head, $4.40; Colborne Crown, $4.20; Apollo, 10¾ oz., $4.30. Add 25c. per 100 lbs. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe.—(See Pipe, Wrought and Galvanized

Iron.—Following prices are on dock. No 1 Summerlee, $22.50 per ton; selected Summerlee, $22; soft Summerlee, $21.50 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron number for number and grade for grade is quoted about the same price as Summerlee. Canadian Iron sells here at about $19.25 to $19.50 per ton, on track.

Lath.—See Lumber, etc

Lumber, Etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph Poles; seven-inch top, cedar poles, 25-ft. poles, $2 each; 30-ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce, 4-ft. x 1½-in., mill run, $3 to $3.25; pine, 4-ft. x 1½-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths. X, $2.10; XX, $2.40; XXX, $2.80.

Pipe.—Cast Iron.—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 40-inch at the foundry. Pipe, specials, $5 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe.—Wrought and Galvanized.—Demand is fair and the market steady: —¼-inch $8.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ⅜-inch, $8.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent off for black, and 59 per cent. off for galvanized. The discount on the following is 72½ per cent. off for black, and 62½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 72½ per cent. for black and 62½ per cent. for galvanized:—2-inch, $36; 2½-inch, $57.50, and 3-inch $75.50; 72½ per cent. off for black, and 62½ per cent. of for galvanized; 3½-inch, $95; 4-inch $1 08.

Toronto, September 24th, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron.—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel.—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates.—⅜-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes.—Orders continue active. Lap-welded, steel, 1¼-inch, 10c.; 1¼-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks.—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $13 to $15 per M., three grades.

Broken Stone.—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto, 60 cents.

Cement.—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm

Copper Ingot.—The market is lower at 15¾ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps.—75c. and $1 per 100; case lots, 5,0000, 20 per cent. off.

Dynamite.—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¾ cents pound, 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1¼c. per hundred. For 10-case lots and over deduct ½ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1½ cent.

Fuses.—Electric Blasting.—Double strength, $3.50 per hundred, advance 5c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 5c. per hundred for each 2-in. wire additional.

Iron Chain.—¼-inch, $5.75; 5-16-in, $5.15; ⅜-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3.55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe.—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $13.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40.60; 6-inch, $52.64. Galvanied Pipe, ¼-inch, $2.86; ⅜-inch, $2.86 ½-inch, $3.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead.—Firmer, $5.25 to $5.50.

Pig Iron.—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar.—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate.—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green, $8, with a prospect of advance. Dealers are fairly busy.

Sand.—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe.—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0.25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00
Double junctions	1.25	2.00	3.25	5.00	16.25
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. H. traps	2.00	3.20	6 50	15.00	.....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes, 9 inches and under or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels.—Active.—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2.75 to $3 per 100 pounds. Extra for smaller sizes of angles and tees.

Sheet Copper.—22c. per lb.

Sheet Steel.—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized.—Apollo Brand.—Sheets, 6 or 8 feet long, 50 or 30 inches wide; 10-gauge, $3.00; 12-14-gauge, $3.00; 16, 18, 20, $3.30; 22-24, $3.40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 pounds. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin.—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel.—Jowett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates.—3-16-inch, $2.40 per 100 lbs.

Zinc.—Spelter.—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, September 23rd, 1913.

Anvils.—Per pound, 11¾ to 12¾c.; Buckworth anvils, 80 lbs. and up, 10¼ to 10¾c.; anvil and vise combined, each $5.50.

Bar Iron.—$2.50 base.

Bars.—Crow, $4.50 per 100 pounds.

Beams and Channels.—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick.—Kiln run per M, $13; sewer per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland.—$2.40 to $2.50 per barrel.

Chain.—Coil, 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7-16, $4.75; ½, $4.50; 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5¾c. Tie out, 70 and 10 per cent.

Copper.—Tinned, boiler, 26¾c., planished 29¾c.; boiler and T. K. pits, plain, tinned, 45 per cent discount.

Dynamite.—$11 to $13 per case.

Galvanized Iron.—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20, $4; 18, $3.95; 16, $3.90; Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30; 22, $4.30; 20, $4.10 per cwt.

Iron.—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26-gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American, $5.15; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe.—Iron, black, per 100 feet, ¼-inch, $2.40; ¾-inch, $2.55; ½-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7.80; 1½-inch, $9.35; 2-inch, $12.50; galvanized—¼-inch, $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch.—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled.—3-16-in., $3.35 base; machinery, $3 base; share, $4.50 base; share crucible, $5.50, cast share steel, $7.50; toe calk, $4.50 base; tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel.—8½ to 15c. per pound

The Canadian Engineer

A weekly paper for engineers and engineering-contractors

KAMINISTIQUIA RIVER BRIDGE, FORT WILLIAM

NEW ELECTRICALLY OPERATED STRAUSS TRUNNION BASCULE BRIDGE FOR THE CANADIAN PACIFIC RAILWAY—CLAIMED TO BE THE LARGEST DOUBLE DECK, DOUBLE TRACK BRIDGE IN USE

THE Canadian Pacific Railway Company are building extensive terminal yards and loading docks on Island No. 1 at Fort William, Ontario. In order to reach this island, it was necessary to build bridges across the Kaministiquia and McKellar Rivers, and, inasmuch as these are both navigable rivers, movable bridges were required, while on account of the rivers being so narrow, it became necessary to use bridges of a bascule type.

The Kaministiquia River, at the point where the railway crosses, has a clear width of channel of 125 feet, but as the railway crosses the river at an angle, a clear span of 180 feet is required. This leaves the channel perfectly clear when the lift is raised into the open position.

The bridge is a single-leaf, double-deck, Strauss trunnion bascule bridge, with the main trunnions at the point of intersection of the bottom chord and the end post of the truss (heel trunnion type), and embraces a 186-foot movable span, giving the required clear channel of 180 feet in the river, and a 40-foot stationary span or tower. The lower deck carries a double track railway and the upper deck two street car tracks in addition to a roadway and sidewalks on each side.

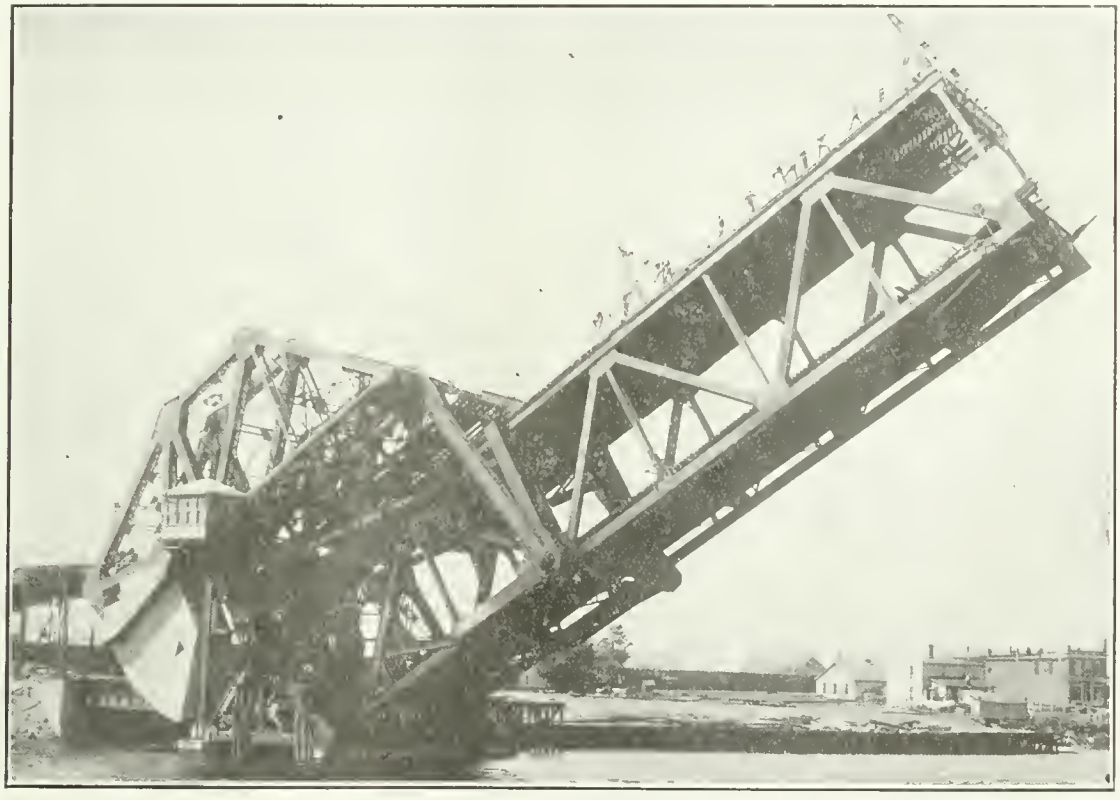

Fig. 1.—The Kaministiquia River Bridge, Fort William, Ont.

The Kaministiquia River bridge is of the Strauss trunnion type, while that across the McKellar River is of the Scherzer rolling lift type. The bridge department of the Canada Foundry Company, Limited, have the contract for the fabrication and erection of both of these bridges, and the bridge across the Kaministiquia River is about completed.

The double-deck feature in bascule bridge construction is said to be out of the ordinary and it is reported that there is no other bridge of the bascule type containing a double deck that is quite as large, although there are a few single-deck bascule bridges under construction that are considerably larger than this one.

There are long approach viaducts on both sides of the river for the electric railway, to enable it to cross the bridge on the upper deck.

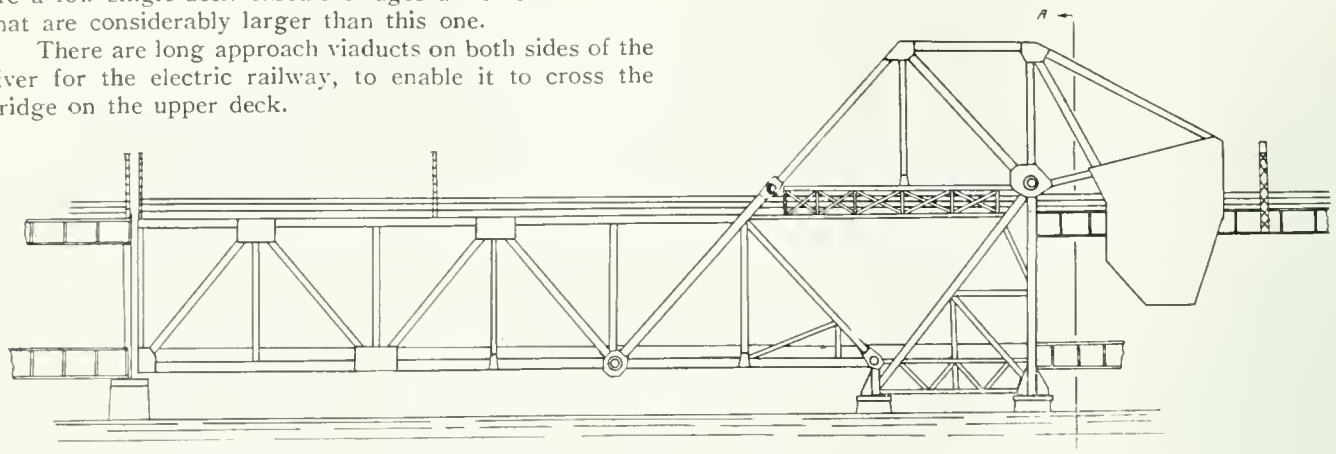

Fig. 2.—Kaministiquia River Bridge, showing General Elevation Diagram.

The construction of the bridge is rather out of the ordinary, as an inspection of the accompanying illustrations will show. The main span is pinioned on a main trunnion at the forward end of the triangular tower. It is for this reason that it is called a heel trunnion type. On the top of the tower a cantilever counterweight arm is trunnioned, the counterweight overhanging the right end of the bridge, the opposite end being connected by a connecting link with pins at both ends to a point along the lower part of the span member, as indicated.

As the main span turns on the main trunnion, the counterweight cantilever at the same time moves through a similar angle, as the pins are so located as to form a parallelogram. The counterweight on the outer end of the counterweight arm is a solid mass of concrete, of such weight as to maintain the main span in equilibrium at all times, the only power required to raise the span being that necessary to overcome the friction of the parts.

The bridge was erected in the open position by means of a wooden erection tower 125 feet high. A derrick on top of this tower took the steel from the cars at the bottom and landed it in place. The placing of the concrete for the counterweight was carried on simultaneously with the erection of the steel, so as to balance the structure at all times. On account of the size of the structure, the available space for the concrete was small, and it was necessary to make concrete weighing as much per cubic foot as possible. Good results were obtained by using iron ore in place of stone in the aggregate, and concrete was obtained weighing about 175 lbs. per cubic foot. This concrete had such great tensile strength that most of the reinforcing ordinarily used in these counterweights was omitted. There was occasion to remove some of this concrete afterward, and it was found to be so tough that the only way it could be removed was by blasting.

Method of Operation.—The operation of the bridge is as follows: Pinned to the front of the triangular towers on each side are operating struts, on the lower end of which are long racks each engaging at the outer end with a pinion. This pinion is connected through gearing to an 85-h.p. motor fitted with solenoid brakes. These two motors are mounted on the towers as indicated in the illustration. The motors, when operating, revolve the pinion, which moves along the rack on the lower face of the operating strut. This action lifts the span. As the bridge moves up, the motors move through the same angle, which in the highest position is 80 degrees.

At the outer end of the span there are two lock motors of 5 h.p. each. These operate the locks through worm gearing. There is also a 3-h.p. motor geared to a crank disc to operate an emergency brake.

When the bridge is closed and ready for traffic, the lock signal switch and the bridge signal switch are both closed, and the contacts in the circuits of the main operating motors and the lock motors are open. To open, the

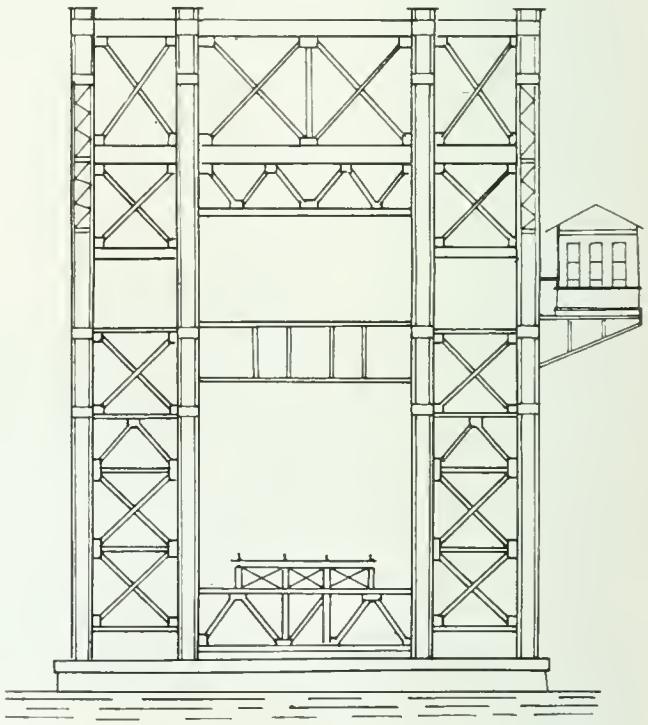

Fig. 3.—Kaministiquia River Bridge—Section A-A (Fig. 2).

danger signal is first set. The action of so doing energizes the contactor points of the lock motor, causing them to close, when, by the closing of the lock motor circuit breaker by the operator, the locks are withdrawn. The lock moving out, automatically changes the light in

the signal tower from white to red, indicating that the bridge is closed to traffic. Similar changes of light occur on the operator's panel.

Until the end locks are withdrawn, the contactors of the operating motors remain open. When withdrawn, these contactors are closed, so that the operator can, as soon as the light signals that the time is proper, energize the main motors through the controllers. The first notch of the controller merely releases the solenoid brake. This position can be used at any time when it is desired to coast. The starting of the span on its upward movement opens the lock motor contactors, so that the latter cannot

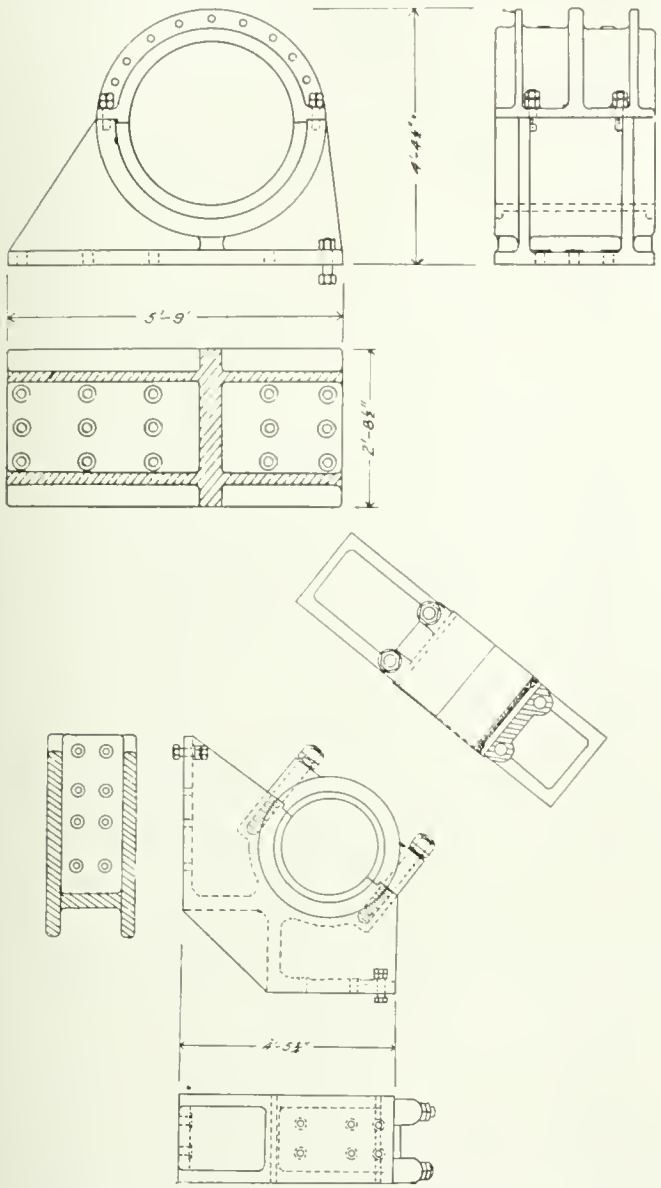

Fig. 4.—Kaministiquia River Bridge—Details of Trunnion Bearings.

operate by accident. The closing of the span is performed by reversing the operations outlined, and the signal lights show up in the same reverse order. Air buffers are provided to take up any shock when the span strikes the abutments. If the bridge is travelling too fast, these air buffers will cause the motors to overload and trip the oil switch, which will automatically put the brakes on. The operating machinery is all interlocked in such a way that every operation must be performed in sequence, and unless the bridge is actually moving up or down, it is held rigidly in position by a brake operated by an independent 5-h.p. motor.

The current for operating this bridge is obtained from the Kaministiquia Power Company and is 2,200 volts, 3-phase, 60-cycle A.C. current. It is stepped down to 550-volt for use on the bridge. The operator's house on top of one of the towers is fitted with a complete electrical control outfit, including switchboard and the necessary attachments.

The bridge is also equipped with a hand-operating mechanism for use in an emergency. It would take four hours to open the bridge with this mechanism.

The total weight of steel in the bridge, exclusive of the approaches, is about 2,500 tons. The counterweight weighs 2,400 tons. The bridge was designed by the Strauss Trunnion Bascule Bridge Company, of Chicago, under the direction of Mr. P. B. Motley, engineer of bridges for the Canadian Pacific Railway. It was fabricated in the Davenport works of the Canada Foundry Company, and all calculations in regard to counterweight were worked out in their engineering department, after the shop drawings were made. The entire electrical equipment was furnished and installed by the Canadian General Electric Company, Limited.

ELECTRIC RAILWAY CONVENTION IN ATLANTIC CITY.

The American Electric Railway Association, whose company members represent over 36,000 miles of track, more than 76 per cent. of the total in the United States, will hold its Thirty-second Annual Convention in Atlantic City, October 13th to 17th. The preliminary announcement of its programme indicates the growing attention which public service corporations are giving to the matter of relations with the public and employees. Technical matters, being left largely to the allied associations, composed of the technical men of the business, the parent association, in which are found the heads of the companies, devotes its attention largely to subjects of general interest to the industry.

Profit-sharing with Employees, The Relation of Carriers to the Development of the Territory They Serve, The Relief of City Congestion, Present Tendency of Public Service Laws and Regulations, Valuation, and Electric Railway Securities from the Investor's Viewpoint, are some of the subjects which will be discussed.

Among the speakers will be Frank Hedley, vice-president of the Interborough Rapid Transit Company, of New York; Paul Shoup, president, Pacific Electric Railway Company, Los Angeles; C. S. Sergeant, vice-president, Boston Elevated Railway Company; J. J. Burleigh, vice-president, Public Service Corporation of New Jersey; W. F. Ham, vice-president of the Washington (D.C.) Railway and Electric Company; C. L. S. Tingley, vice-president of the American Railways Company, Philadelphia; C. N. Duffy, vice-president, the Milwaukee Electric Railway and Light Company; Richard McCulloch, vice-president, United Railways Company, of St. Louis; C. W. Beall, of Harris, Forbes & Company, New York; A. D. B. Van Zandt, Detroit United Railway Company; David W. Ross, vice-president, Interborough Rapid Transit Company, New York; Frank Bergen, general counsel, Public Service Corporation, of New Jersey; C. M. Rosecrantz, general counsel, the Milwaukee Electric Railway and Light Company, and Assistant Surgeon-General W. C. Rucker, of the United States Bureau of Public Health.

NEW JERSEY REGULATIONS FOR THE DESIGN OF SEWERAGE SYSTEMS AND DISPOSAL WORKS.

AT a recent meeting of the Board of Health of the State of New Jersey, a set of rules and regulations governing the submission of designs for waterworks or sewage works were adopted. These rules have been under consideration for about a year, and the necessity for them has increased daily. Plans are submitted at the present time in all sizes up to 6 feet by 10 feet, and on all kinds of paper from the wrapping kind up to tracing cloth. It is also an unfortunate circumstance that some few engineers who have worked along other lines will accept work designing municipal sewage disposal or water purification plants apparently without investigating the underlying principles as thoroughly as is desirable. It then becomes necessary for the authorities to gather detailed data regarding the project, which very often cannot be done as efficiently as would be best because of the small number of engineers which may be employed with the present annual appropriation.

The present rules are therefore intended to prevent loss of time incident to the collection of fundamental data, upon which the design is based, and also to make the plans and reports more uniform in character. Before taking final action they were submitted to several of the leading sanitary engineers, with the request that comments and criticisms be made, so that no unjust provisions should be included which would cause unnecessary hardship or expense upon the part of the engineers. Many helpful suggestions were made by these engineers.

The following is extracted from the adopted rules and regulations:—

Sewerage Systems and Sewage Disposal Works.—The plans for a complete sewerage and sewage disposal system shall include the following:

A general map of the municipality or sewerage district.

Profiles of all sewers proposed.

Details of construction of manholes, flush tanks, and special structures pertaining to the sewers.

General and detailed plans for disposal works.

A comprehensive report upon the proposed system by the designing or consulting engineer. This report to be typewritten upon letter-size paper, and the sheets firmly bound together.

A preliminary report, containing data and information sufficient for the complete understanding of the project may be submitted to the State Board of Health for their consideration, prior to the submission of detailed plans.

Map or General Plan.—The general plan referred to shall be drawn to a scale not greater than 100 nor less than 300 feet to 1 inch, and shall show the entire area of the municipality or district. If the municipality is greater than two miles in length the map may be divided into sections, conforming in size to those mentioned under "Drainage." The sheets shall be bound together and a small index map supplied, showing by number the area covered by the various sheets. A general plan shall accompany each application, in the case of a new sewer system or any extension or modification of any existing sewer system unless such general plan has already been submitted.

The map shall show all existing or proposed streets, the surface elevations at all street intersections, and contour lines at intervals of not more than 10 feet.

If it is intended to defer the construction of sewers in some of the streets, the plan shall show that sewerage facilities are provided for all such sections of the municipality or sewerage district. The plans shall also clearly show the location of all existing sewers, either "separate" or "combined," the location of the disposal works, and the location of existing and proposed sewer outlets or overflows. The true or magnetic meridian, the town or borough lines, title, date, scale, direction of flow and average water elevation of the stream shall also be clearly shown. The elevation of the highest known freshets at the outlets and site of the disposal plant shall be given. Any area from which sewage is to be pumped shall be shown by light shading, coloring or other distinctive marks.

Letters and figures shall be clearly and distinctly made. Sewers to be built at present shall be shown by solid lines, and sewers to be constructed later shall be shown by a line of dashes, as - - - - - - - - -. Existing sanitary sewers shall be shown by the following symbol, ... , and combined sewers by a dot and dash, .—.—.—. All topographical symbols used are to be the same as those of the United States Geological Survey.

Elevations of the surface of the streets should be placed outside the street lines in the upper right angle, or opposite their respective positions in the street. The elevations of sewer inverts should be shown at street intersections, ends of line, and wherever a change of grade occurs. The elevations of the sewer shall be written close to the point to which they refer, parallel with the sewer line and between the street lines. The elevations of surface shall be shown to the nearest 1/10 foot; those of the sewer invert to the nearest 1/100 foot. The sizes and gradients of all proposed and existing sewers shall be marked along the line of the sewer.

All sewer appurtenances and unusual features, such as manholes, lampholes, flush tanks, siphons, pumps, etc., shall be designated on the plans by suitable symbols and referenced by a legend near the title.

Profiles of all sewers over 8 inches in diameter and of all 8-inch sewers, where gradients less than that given below are used, shall accompany the application. Profiles of all sewers must be approved before they are constructed.

Profiles of sewer lines shall be prepared and drawn to such a scale as to clearly show the structural features of the sewer. For ordinary use, the following scales are suggested: Vertically, 10 feet to 1 inch; horizontally, 100 feet to 1 inch. Both scales must be clearly shown upon each sheet. Upon these profiles shall be shown all manholes, flush tanks, lampholes, siphons, and stream crossings, with elevations of stream bed and normal water. Figures showing the sizes and gradients of sewers, surface elevations, sewer inverts, etc., should be shown with the same frequency as required for the map.

Grades, Etc.—The following gradients for sewers flowing half full are suggested as minimum grades for ordinary use, as with careful construction a theoretical velocity of approximately two feet per second can be obtained:—

Size of pipe.	Fall in feet per 100 feet of sewer.
8 inches	0.40 feet
10 inches	0.29 feet
12 inches	0.22 feet
15 inches	0.16 feet
18 inches	0.12 feet
20 inches	0.10 feet
24 inches	0.08 feet

The sewers should have a capacity when flowing half full sufficient to carry twice the future average flow twenty-five years hence, plus a sufficient allowance for ground water infiltration.

When grades lower than those given are used, an explanation and reasons for the use of such grades should be included in the engineer's report. On each sheet of profiles must be given, under the title, an index of the streets appearing on that sheet. Profile sheets shall be numbered consecutively.

Detail drawings of sewer sections except where terra cotta or iron pipe is used, and of all sewer appurtenances, such as manholes, lampholes, flush tanks, inspection chambers, siphons and any special structures, shall accompany the general sewer plans.

The detail plans shall be drawn to such a scale as to show suitably and clearly the nature of the design and all details, such as manhole frames and covers, iron pipes, valves, gates, etc.

Disposal Works.—The plans for the disposal works shall include a general plan upon which reserve areas or future extensions are clearly shown, and detail plans of the various units and structures which comprise the plant.

A weir or other measuring device shall be provided at some convenient point, and the installation of a recording device is recommended, and in particular instances may be required.

The detail plans shall show longitudinal and transverse sections sufficient to explain the construction of each unit. They should also show the distributing and drainage systems, general arrangement of any automatic devices, sizes of stone, gravel, or sand used as filtering material, and such other information as is required for the intelligent understanding of the plans.

Drawings.—All drawings submitted shall be neatly and plainly executed and may be traced directly on tracing cloth, printed on transparent cloth, or printed on any of the various papers which give distinct lines. All prints shall be clear and legible.

With the exception of the map, the following dimensions are suggested for ordinary use: Distance from top to bottom, 20 or 30 inches; length, 24 inches, 32 inches, 40 inches or 48 inches, or thereabouts. By this section it is intended to prevent the use of long profiles and unnecessarily large maps, which are difficult to file or to use.

Each drawing shall have legibly printed thereon the name of the town or persons for whom the drawing is made, the name of the engineer in charge, the date, the scale, and such references in the title as are necessary for the complete understanding of each drawing.

A report, written by the designing or consulting engineer, should accompany all plans for complete sewerage systems, and shall give all data upon which the design is based, such as:

Information Concerning Sewer Systems.—(a) The nature and extent of the area which it is proposed to include within the present system of sewerage, and of the area which it is planned shall ultimately drain into this system.

(b) The population to be served, both present and estimated for twenty-five years hence.

(c) The estimated per capita daily flow of sewage to be cared for.

(d) The total and per capita water consumption of the town at the present time.

(e) The allowance made for leakage into the sewers.

(f) The estimated daily flow of sewage, including leakage.

(g) The character of the sewage (whether domestic or including manufacturing wastes, and in case of the latter, the nature and approximate quantity of the same stated in specific terms).

(h) Method of flushing or periodically cleaning the sewers.

(i) That portion of the sewers to be built at the present time.

(j) The minimum grades of sewers for each size used.

(k) If there are sections which cannot drain into this system, the extent of such sections and the probable future disposition of the sewage from these sections.

(l) Distance of sewer outlet from shore and depth of water at mean tide at outlet, if outfall discharges into ocean or large stream.

A list of bench marks or fixed elevations should be included in this report.

Information Concerning Disposal Plant.—With regard to the disposal plant, the engineer's report shall cover the following subjects:—

(a) The method of disposal to be adopted and a description of the units of the system.

(b) The rate of working of each unit.

(c) If disinfection is to be used, the name of the disinfecting substance, the quantity per million gallons of sewage and the method of application.

(d) The nature of the body of water into which the effluent discharges, with particular reference to the run-off during dry weather.

(e) The disposal of sludge.

(f) All conditions peculiarly characteristic of the locality and which in any way affect the design of the system.

(g) Special devices used in connection with the disposal system.

(h) Special methods of maintenance or operation of the system.

(i) The results expected from the purification system.

(j) Explain any provisions for reserve units in pumping plants, pipe lines, filters, etc.

Specifications and Estimate of Cost.—Specifications for the construction of the system of sewers and sewage disposal works and an estimate of the cost of the same shall accompany all plans for new or original systems. With plans for extensions of existing systems, specifications may be omitted, provided that these extensions are to be constructed in accordance with specifications filed previously with original plans.

If the plans are solely for the extensions of an existing system, then only such information as is necessary for the comprehension of the plans will be required. This information must in general conform to the above requirements for a complete system.

Systems on Separate Plan.—Under ordinary circumstances the board will approve such plans only when designed upon the separate plan, in which all rain water from roofs, streets and other areas and all ground water, other than unavoidable leakage, is to be excluded.

No by-passes which may allow raw or partly purified sewage to be discharged from the sewers or disposal works shall be included in the plans, except by special permission of the board.

Water Supply and Water Purification Systems.—The plans for a complete water supply and water purification system shall consist of the following parts:

A general plan of the municipality or district, showing the proposed system.

Detailed drawings showing construction of any special structures in the distribution system.

General and detailed plans for the water purification works.

A comprehensive report upon the proposed system by the designing or consulting engineer. This report to be typewritten upon letter-size paper, and the sheets firmly bound together. A preliminary report, containing data and information sufficient for the complete understanding of the project may be submitted to the State Board of Health for their consideration, prior to the submission of detailed plans.

General Plan.—The general map referred to in paragraph 2 shall be drawn to a scale not greater than 100 nor less than 300 feet to 1 inch, and covering the entire area of the municipality or district to be supplied with water, and shall accompany each application in the case of a new water system, or any extension or modification of any water supply or water purification system, unless such a general plan of the entire area has been previously submitted.

If the municipality is greater than two miles in length, the map may be divided into sections, conforming in size to those mentioned under "Specifications." The sheets shall be bound together and a small index map supplied, showing by number the area covered by the various sheets.

This map shall show all existing or proposed streets, the surface elevations of all street intersections, and the elevations of the principal parts of the water system, such as water at the intake, in the reservoir or standpipe, etc. The map should show that water supply facilities can be provided for all sections of the municipality or district, even though the construction of pipe lines in some of the streets is to be indefinitely deferred. The location of intakes, valves, hydrants, reservoirs, pumps, standpipes and purification plant, and any special structures, shall be shown and referenced in a legend near the title. The size of pipes shall be written between the street lines and along the pipe. The map shall also show the true or magnetic meridian, title, scale, date, the municipal or district boundaries, the mean, low and high water elevations of water at the intake. If the site of the pumping plant is subject to flooding, the elevation of the highest known flood water must be given.

Letters and figures shall be clearly and distinctly made. Pipe lines to be built at present shall be shown by solid lines and those to be later constructed shown by broken lines. All topographical symbols used are to be the same as those used by the United States Geological Survey.

The elevations of the street intersections shall be placed outside the street lines in the upper right-hand angle or opposite their respective positions in the street.

Detail drawings of all special appurtenances, such as blow-offs, siphons, intakes, conduits, reservoirs, collecting galleries, filters, etc., shall be submitted.

Profiles of long conduits or pipe lines may be plotted to a convenient scale and shown on sheets of the sizes mentioned below.

Purification Works.—The plans for the purification works shall consist of a general plan upon which reserve areas or future extensions must be shown, and also the general layout of the various units of the process, together with the piping system.

The detail drawings shall include longitudinal and transverse sections sufficient to show the construction of each unit and part of the plant. They shall also show the distributing, drainage and cleansing systems, general arrangement of any automatic devices, sizes and depth of stone, gravel or sand used for filtering material, and such other information as is required for the intelligent understanding of the plans.

All drawings submitted shall be neatly and plainly executed and may be traced directly on tracing cloth, printed on transparent cloth or printed on any of the various papers which give distinct lines.

The following dimensions are suggested for ordinary use, with the exception of the general map: Distance from top to bottom, 20 or 30 inches; length, 24 inches, 32 inches, 40 inches or 48 inches or thereabouts. By this section it is intended to prevent the use of unnecessarily long or large maps, which are difficult to file or to use.

Each drawing shall have legibly printed thereon the name of the municipality or persons for whom the drawings are made, the name of the engineer in charge, the date, the scale, and such references in the title as are necessary for the complete understanding of each drawing.

Engineer's Report.—A report, written by the designing or consulting engineer, shall be presented with all plans for complete systems, and shall give all data upon which the design is based or which is required for the complete understanding of the plans.

When a purification or treatment plant is to be constructed, a measuring device shall be provided at some convenient point, and the installation of a recording device is recommended, and in particular instances may be required.

If no purification process is provided, the nature and extent of the watershed, with special reference to its sanitary condition, shall be fully and explicitly discussed, together with proposed methods and regulations for the prevention of accidental or other pollutions.

A small scale map of the watershed, showing the roads and the number and character of buildings, shall be included in the report. Other features which should be discussed in the report are: Storage capacity, average depth, general nature and area of the storage reservoir, liability of odors or tastes in supply, and removal of color, iron, or hardness.

If the water supply is to be taken from wells, describe the number, depth, size and construction of the same;

method of pumping, capacity of pumps, kind of strainer used, nature of ground through which wells will be driven, and probable flow of the wells. If collecting galleries are to be used, describe their construction.

Information Concerning Purification Plant.—The following information is required respecting the purification plant: The method of purification and a description of the units of the system; the rate of operation of each of the systems; the rate of operation of each unit of the plant; if any chemicals are used, the nature and quantity of each with a description of the appliances for adding the same to the water; a description of all conditions peculiarly characteristic of the water or locality which in any manner affect the design or operation of the system; a description of all special appliances used, any special methods of maintenance or operation of the plant, and the extent of purification expected or guaranteed.

If for purposes of fire protection it is necessary to provide by-passes, by which partly treated or raw water can be turned into the mains, they shall have valves upon them of such a character that they may be properly sealed by the State Board of Health.

The report should further include a description of the nature and extent of the area to which it is proposed to supply water, or which will ultimately be supplied from the system, the quantity of water to be supplied daily, and the population to be served, the portion of the system to be constructed at present and the minimum depth of pipe below the surface of the ground. A description of any provision for future units of pumping plants, filters, etc., should be given.

Should there be areas in the municipality or district which, on account of topography or for other reasons cannot be supplied with water, a definite statement to this effect must be made and the probable future supply of this omitted territory should be discussed.

Specifications.—Specifications and an estimate of the cost for the construction of water supply and water purification systems shall accompany all plans for new or original systems. With plans for extensions of existing systems or plants, specifications may be omitted, provided that these extensions are to be constructed in accordance with specifications filed with the original plan.

Extensions of Present Systems.—If the plans are solely for the extension of the existing system, only such information as is necessary for the comprehension of the plans will be required. This information shall, in general, conform to the above requirements for a complete system.

The application for approval of plans shall be made by the proper municipal authorities, persons for whom the work is to be done, or their properly authorized agents, upon blank forms, which will be supplied by the board.

The above regulations were prepared by C. G. Wigley, engineer of the board, under the supervision of R. B. Fitz-Randolph, chief of the Division of Food, Drugs, water and Sewerage, and adopted by the Board of Health of the State of New Jersey, June 23, 1913.

MEETING ON IRON AND STEEL.

A meeting of the American Institute of Mining Engineers under the auspices of the Iron and Steel Committee of the Institute, will be held in New York on October 16 and 17.

THE FINANCING OF ROAD ENGINEERING.

RECENTLY The Surveyor (London) published an article by Reginald Ryves, A.M.I.C.E., containing suggestions as to the policy which should be adopted in the United Kingdom for the raising of funds for road maintenance and improvement, and as to the manner in which these funds should be expended. Highway finance is a very different problem in Canada from what it is in the British Isles, where roads are short and population is dense; but there are many suggestions in the article mentioned which Canadian highway engineers will find practical.

The papers contributed to the Third International Road Congress on the subject of highway finance do not admit of summary in a form conveying correct ideas as to the merits of different methods of raising and applying revenue for road construction and maintenance; the reports are, nevertheless, very illuminating if we study the methods pursued in each country with due consideration for the prevailing circumstances. In nearly all countries the financing of road construction and maintenance is closely bound up with or is greatly influenced by the general principles of taxation adopted, and beyond this the methods followed depend very much upon the stage of development which the road system has reached. In some countries considerable sums are raised by the taxing of vehicles and from tolls, and in some cases payments are exacted from persons who habitually, or occasionally, use the roads in such a manner as to cause unusual wear and tear. In India vehicles are taxed and tolls are collected, and in some parts of that country the sums raised from tolls collected by the district boards are not only sufficient to defray the expenses of maintaining the roads, but leave considerable surpluses for other purposes. Such a tax is not more unreasonable in principle than the tax in this country upon certain classes of users of postal services, who pay much more than the cost of the service for the benefit of the country at large.

The expediency of any system or of particular measures depends upon the relations otherwise established between local and national finances, which may vary greatly, the national treasury being, in some countries, largely replenished by contributions from local taxation.

We have also to consider the extent to which the roads are used by certain groups of traders as well as in general trade and commerce, the manner in which the population is distributed, and the nature of their occupation. The equity of any particular system also depends upon whether the soil and climate, taken together, are much more favorable to road maintenance in some localities than they are in others. In countries in which the climate is much the same in all parts, and where the geological conditions are equally favorable as regards the cost of maintaining roads, and where, further, the population and local resources are fairly evenly distributed, it may be equitable and economical to charge the local authority with the cost of maintaining all roads, even when some of these carry a large proportion of through traffic.

When, however, the main roads traverse varying strata and areas differing considerably in climate, and where the population is unevenly distributed, and is engaged in many different callings, it is not equitable to charge the local authority with the cost of maintaining

*The reader is referred to an article in last week's issue descriptive of the Road Board and its methods of financing.

roads for through traffic, and may even be inequitable to make each authority maintain the roads for local traffic, unless the area of any such authority is fairly large. In an almost purely agricultural country, or one in which the distribution of industries and of the soils is very symmetrical, the consideration that the more costly roads are usually those running through rich soils is of some importance; but it is of very small importance in a country which is complex as regards soils, climates, and the distribution of population and of wealth, more especially when the population of that country includes a large spending element as distinct from the elements of primary economic significance.

The United Kingdom is such a country. In it financial equity can only be secured by defraying a considerable part of the costs of road maintenance out of the King's taxes, and a fair economic distribution of burdens can only be secured by something in the nature of a wheel tax, the whole of which would not necessarily be paid by those upon whom it was imposed, but would naturally be to a great extent, distributed among the persons directly or indirectly benefiting from the carriage of goods over the roads. The customer pays. All classes do not benefit equally from the existence of an efficient highway system, and those who use the roads as a means of rapidly amassing wealth, or as an accessory in the dissipation of wealth, should be taxed to pay for road maintenance, not only because they use the roads for such purposes, but also because they are the strong, active and efficient elements in the community. To a considerable extent roads are maintained by persons who use them and benefit by them less than any other classes of the community. It is desirable that taxes raised from users of the roads should be devoted to road maintenance, not as a punishment for the use of the roads, but because there will be a constant proportion between the amount of wear and tear and the amount of money raised, and it is here suggested that a wheel tax should be imposed on all vehicles, including bicycles, for the purpose of road maintenance. The sums raised from motor and petrol taxes should be included. These sums are at present devoted to a quite distinct purpose—that is, road improvement. This is much better than carrying out such improvements by means of loans (the loans granted by the Road Board* being only such in a secondary sense, and involving no charge upon the community for interest), but this must be regarded as a temporary expedient for rendering the road system as a whole more effective, and the aim should be to establish a state of equilibrium in which all sums raised by taxes on vehicles should be devoted to road maintenance, and to such minor improvements as do not lead to an increase in the cost of maintenance.

So far the improvements carried out with the Road Board funds have largely been, as a Scottish reporter to the Road Congress has expressed it, "quasi-permanent" rather than permanent in the true sense, and no attempt has yet been made to undertake generally such engineering works as are needed in some cases to make roads more efficient, and, in many other cases, to render them less costly in annual maintenance. It should be clearly understood that the policy here advocated—viz., the attainment of an equilibrium, and the allocation of Road Board fund to road maintenance proper—includes as a preliminary the extension of the wheel tax at the earliest possible date, the "hoarding" of Road Board funds until a sufficient sum is in hand and the carrying out once for all in each case, on definite stretches of road, such improvements as are necessary. It is further suggested that the expenditure of the Road Board fund should be to some extent rhythmic, and that, in addition to the annual expenditure on maintenance, there should be a steady hoarding of a surplus to be devoted, from time to time, to works of road improvement. One advantage of this system would be that, while the money was accumulating, there would be time for investigations into the different schemes of road improvement put forward, for the preparation of the plans, and for all preliminary work, so that when the time came to spend the money the whole of the improvements staff could be employed in furthering the executive work. Outside the larger cities, at any rate, the carrying out of road improvements by means of loans on which interest has to be paid is not sound finance. How can it be good finance to pay, say, £1,600 for an improvement which actually cost only £1,000? In the case of a long-term loan the total sum paid may be more than twice that actually expended on the work.

In the United Kingdom the conditions of trade and of business and personal activitity generally are such that a wheel tax on the broadest possible basis is a very fair method of raising revenue for the purpose of maintaining roads. If it can be argued that persons who do not use the roads benefit indirectly as much as those who do use the roads, it may equally well be argued that persons who do not actually use vehicles pay indirectly a full share of the cost of running such vehicles as are used in the dirtribution of goods. With a better organization of road maintenance, including an increase in the sizes of administrative areas, closer relations between one highway authority and another, and some general supervision of finance, procedure and staffs, by a body such as the Road Board, the funds raised at present by local taxation, added to those derived from vehicle and petrol taxes, and increased by an extension of the wheel tax would, it may safely be asserted, be amply sufficient for all purposes of road maintenance for a very long time to come.

CORUNDUM.

In spite of the large increase, in late years, in the manufacture and consumption of artificial abrasives, such as carborundum, alundum, etc., natural corundum is still preferred for certain purposes, and the Canadian deposits of this mineral yield practically the entire supply. In 1912 the production amounted to 1,960 tons, valued at $239,091, according to statistics contained in Economic Minerals and Mining Industries of Canada, by J. McLeish.

The corundum mines are situated in the eastern portion of the province of Ontario, in the townships of Carlow and Raglan, and mining operations have been in progress since 1900. At present, mining is being conducted solely by one corporation—the Manufacturers' Corundum Company—who have acquired the mines and mills formerly operated by the Ontario Corundum Company, in Carlow, and the Canada Corundum Company, in Raglan.

The corundum occurs in the form of crystals of various sizes, disseminated in syenite, and is won by quarrying the matrix, hand-sorting the broken rock, and crushing the richer material, with subsequent wet concentration. The average corundum content of the rock treated does not much exceed 6 per cent., and, as from 1½ to 2 per cent. are lost in concentrating, the recovery represents about 4 per cent. of the crude material.

Corundum-bearing rocks were first recognized in this area in 1897, and the mineral is found sparingly, but widely distributed in the rocks of this district.

MECHANICAL GRAVITY FILTRATION AT SASKATOON

TYPICAL RECORDS OF PLANT OPERATION WITH RESPECT TO QUANTITY OF WATER FILTERED, CHEMICAL TREATMENT, BACTERIAL REMOVAL AND COSTS.*—DESCRIPTION OF THE PLANT

By GEORGE T. CLARK,
City Engineer, Saskatoon.

THE city of Saskatoon obtains its water supply from the south branch of the Saskatchewan River. This river and its tributaries are being polluted by the sewage from a number of towns and cities, including Calgary, McLeod, Lethbridge and Medicine Hat. In addition to being contaminated, the water of this river is very turbid at certain seasons of the year, and it is generally believed that a turbidity in the water such as is presented in this case, consisting to a large extent of fine quartz particles, predisposes to enteric conditions.

For these two reasons, therefore, namely, periods of excessive turbidity and danger of contamination, the civic authorities decided that it was advisable to take the necessary steps to purify the water, and the writer was requested by the city to report on the subject of filtration. Before doing so, some filtration plants of different types were visited, including among others those at Albany, N.Y.; Hackensack, N.Y.; Harrisburg, Pa.; Philadelphia, Pa., and Columbus, Ohio; and the outstanding features of each were noted.

Requirements of Water Being Used for Domestic Purposes.—Water which is required for domestic purposes should possess the following qualities:—

(1) It should be free from disease-producing germs.

(2) It should be free from those allied organic forms, which are not conducive to health, although they may not as yet be recognized as accompanying disease.

(3) It must be uniformly clear and free from turbidity, whether such be produced by mineral or organic matter.

(4) It must be free from color, odor and taste.

The methods adopted by the city of Saskatoon to accomplish these results may be divided into three steps, viz., sedimentation, filtration and sterilization.

Sedimentation.—The sedimentation basin has a capacity sufficient to give the water 8 hours' subsidence, when the filter is working at full capacity, and is divided into two parts by a weir wall across the centre. In the north half of the basin, plain sedimentation takes place, and in the south half, sedimentation and coagulation.

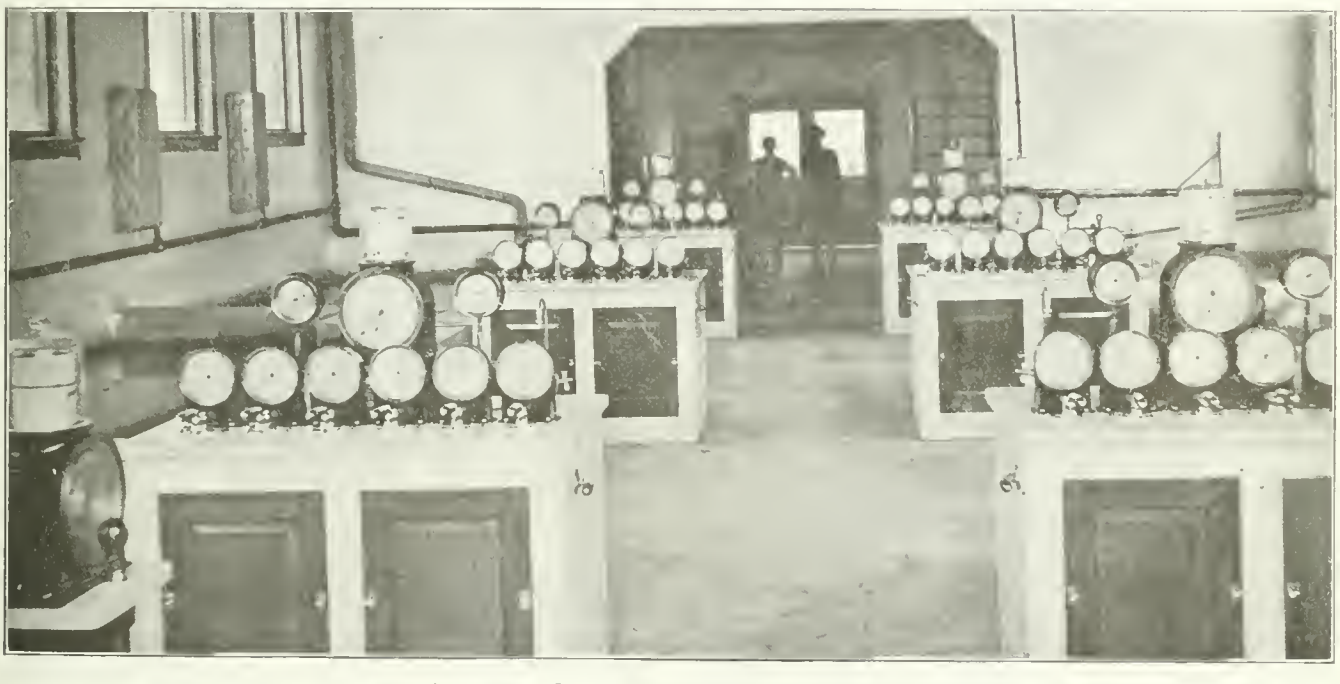

Fig. 1.—Section of Laboratory, Saskatoon Filtration Plant.

The coagulant used is sulphate of alumina, because the water has a sufficient alkalinity content, so that sulphate of alumina presents the necessary reaction to form an alumina hydrate, which, in precipitating, coagulates much of the organic matter, and drags down the finer suspended matter.

Provision has been made for applying the coagulant at three points: (1) When the water enters the basin; (2) when it passes over the weir; (3) just before it enters the filters.

The solution of sulphate of alumina used is 350 lbs. to 1,980 Imperial gallons of water or 1.8% solution.

Filtration.—The three best known types of filters were duly considered before a decision was arrived at, as to which one was best suited to our purpose. A very

* These Tables formed the basis of Mr. Clark's paper to the Canadian Public Health Association in Regina last month.

strong point in favor of the pressure filter was that, with this type of installation one system of pumps would have been all that was necessary to deliver the water from the river direct to the distributing system, whereas, with either of the other two systems a double pumping is necessary. The excessive turbidity of the water, however, made preliminary sedimentation absolutely necessary, and the idea of installing pressure filters had, therefore, to be abandoned. The gravity mechanical filter was chosen over the slow sand type for the following reasons:—

(1) The mechanical filter will handle 50 times more water per unit of area per day than the slow sand filter.

(2) The mechanical filter is, on account of being much smaller in area, much more easily protected from excessive cold.

(3) The initial cost of construction is about one-half.

(4) The cost of operating slow sand filters in the case of highly turbid waters is much in excess of mechanical filters.

(5) Cleaning the surface of slow sand filters requires the dangerous personal contact of workmen.

the form of a .5 per cent solution, and is applied to the water at the point where it enters the filter beds.

The total amount of hypochlorite used by us since the plant was first put in operation in June, 1912, has been only 900 lbs.

Results.—Table I. appended hereto is a typical monthly operating cost sheet. It will be noted that the chief items of expense are salaries of superintendent and operators, and the charge for interest and sinking fund. The cost for filtering for the month of August, 1913, per 1,000 Imperial gallons was 1.93 cents.

Table II. shows in detail the operation of the plant during the month of August. The quantity of water pumped and filtered, the chemicals used, and the turbidity of the water is given for each day.

Table III. illustrates clearly how the amount of coagulant required, and the amount of wash water used, vary directly as the turbidity. The amount of coagulant required varies from about one-quarter to one and one-half grains per gallon with an average for 8 months of ¾ of a grain, while the amount of wash water required

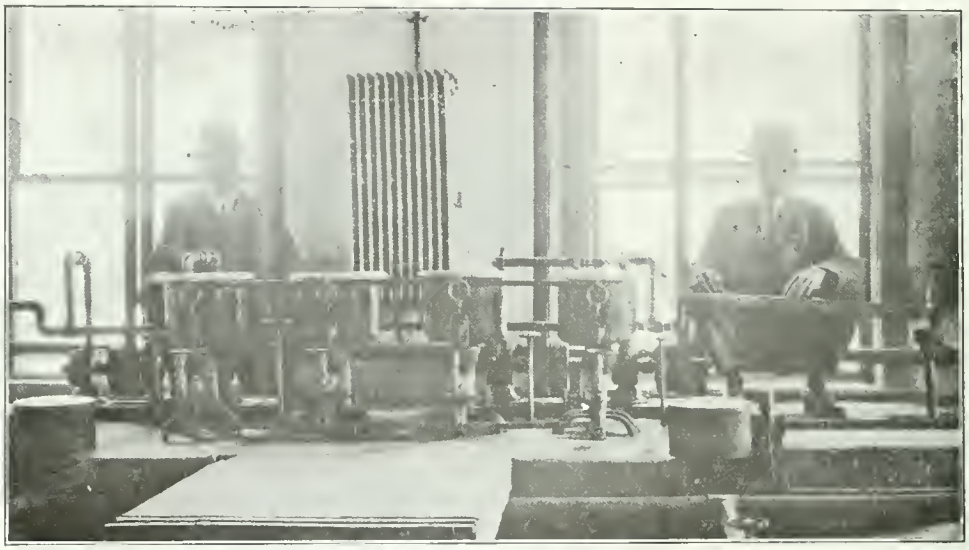

Fig. 2.—Apparatus for the Chemical Treatment, Saskatoon Filtration Plant.

Description of Plant.—The mechanical plant installed consists of the following:—

(1) One filtered water basin, capacity 125,000 Imperial gallons.

(2) Six concrete filter units, each with an effective filtering area of 290 sq. ft. The filtering material consists of an 8-inch layer of gravel, graded in sizes from .2 to .5 of an inch, the larger pebbles being placed on the bottom, and a 30-inch layer of sand graded from .36 of a millimeter to .55 of a millimeter, and consisting of hard silicious material free from vegetable matter or other foreign substance.

(3) A wash water pump and motor.

(4) An air compressor.

(5) A complete apparatus for preparing and feeding sulphate of alumina and hypochlorite of lime.

(6) Hydraulically operated valves for controlling the operations of the filter units.

Sterilization.—This is the third operation, which is sometimes required to be performed in cases where harmful bacteria are still present in the filtered water. It consists in our case of the addition of hypochlorite of lime in

varies from two and one-half to five per cent., with an average for 8 months of 3½%.

Table IV. shows that although the superintendence and interest and sinking fund remain constant, the turbidity is of sufficient range to vary the cost of filtering from a minimum of 1.4 cents per 1,000 Imperial gallons to a maximum of 2.16 cents, or an average for the eight months of 1.77 cents.

It is of interest here to note that the turbidity of the South Saskatchewan River water varies from 30 to 3,750 parts per million.

Table V. shows the bacterial removal efficiency for 8 months. For 6 months the removal has been 97%. For the month of February the removal was only 80%, but the bacterial count in the raw water was very small. The high count in the raw water in March is accounted for by the melting of the snow during that month, and the consequent depositing in the river of the filth collected in the snow during the winter months, and also by the increased volume of water underneath the ice scouring the river bottom.

A study of these records shows that the plant has, in respect to wash water required and bacterial removal, ful-

Table II.—Summary of Water Filtered and Chemical Distribution for Month of August.

THE LINCOLN HIGHWAY.

Thirteen States will be traversed by the Lincoln Highway, the route of which has been definitely announced. They are New York, New Jersey, Pennsylvania, Ohio, Indiana, Illinois, Iowa, Nebraska, Wyoming, Colorado, Utah, Nevada and California.

Starting in New York City, the Highway passes through Jersey City, Newark and Trenton to Philadelphia, then west to Pittsburg, through the north central section of Ohio, over to Fort Wayne and South Bend, skirts Chicago, enters Joliet, Rochelle, Sterling and other Illinois cities, reaches Iowa at Clinton and leaves at Council Bluffs, passes through Omaha, goes to Denver and north to Cheyenne, west through Green River and Evanston to Salt Lake City, finds its way into Nevado by way of Tippet's ranch, and after reaching Reno, goes to Lake Tahoe, California, finally ending on the Pacific seaboard at Oakland and San Francisco. The directors of the Association have endeavored to select a route of easy grades, yet combining the scenic splendors of the country.

Makers of carbon black at Wilsonburg, W. Va., obtain free power in a novel manner. The product is deposited from the flames of natural gas, and power was originally supplied by a steam boiler and engine. The gas issued at a pressure of 950 pounds from a well 3,000 feet deep. It was suggested that this pressure might be utilized, and accordingly the gas was led in place of steam to the engine, which was thus driven, and acted as a reducing valve, delivering the gas at low pressure to a discharge tank feeding the carbon buildings. The engine, requiring no attendant, continues to give uniform and satisfactory service.

The Canadian General Electric Company, Limited, have just acquired by purchase all the plant and assets of the Stratford Mill Building Company, at which plant in future will be manufactured not only the flour mill machinery heretofore manufactured by the Stratford Mill Building Company, but also the wider range of machinery and equipment as produced by the Allis-Chalmers Company. Mr. William Preston, who has been the president of the Stratford Mill Building Company, will now act as manager of the flour mill machinery department of the Canadian Allis-Chalmers Company.

BELT CONVEYERS.

By Reginald Trautschold, M.E.

(PART II.)

(Continued from page 480, Sept. 18th issue.)

THE operation that presents the greatest difficulty in any belt conveyer system, if wear and tear are to be kept at a minimum, is that of loading the conveyer, for it is at the instant that the load comes in contact with the conveyer belt that the main wear occurs and greatest depreciation of equipment takes place. Loading should always—when practicable—be accomplished through chutes discharging in the direction of conveyer travel, and it is in the design of these chutes that one of the greatest problems of an efficient installation is presented. The slope of the chute should be such that the velocity of the material as it leaves the chute is as nearly as possible the same as that at which the conveyer belt is running. The bottom of the chute should also be provided with an adjustable curved lip, conforming to the trough of the belt and turning upward sufficiently to throw its discharge forward in a plane approaching that of the conveyer belt, thus minimizing the shock of impact as the load strikes the belt and is carried forward by it. The loading chute should always be located slightly in advance of a troughing idler and should be provided with parallel skirt boards extending along the conveyer and parallel to the belt, an inch or so above it, for a distance equal to about twice the distance between troughing idlers—i.e., a troughing idler should be located just back of the chute, one not quite midway along the skirt boards, and one just before the load leaves the confines of the guides. These skirt boards should be separated by a space a few inches less than the width of the belt—less than the section of belt covered with load—and should advisably have triangular cleats attached to their inner sides for the section lying in the path of the material descending the chute—such cleats tend to throw the load towards the centre of the conveyer belt and thus minimize necessary rearrangement of load as it passes from between the skirt boards.

One drawback to what would otherwise be probably about the most efficient and economical mechanical conveying system that could be devised is that belt conveyers are limited as to the inclination at which they can be efficiently operated, necessitating considerable space if any considerable elevation is to be attained; that is, the height through which a load can be raised in a given distance. This limitation is governed to considerable extent by the angle of repose of the material conveyed—particularly the angle of repose of the material on the belt—for just as soon as the inclination of the conveyer is great enough to cause a slippage of the load on the belt disastrous wear occurs and depreciation more than offsets any possible gain of simplicity and convenience of system, etc. The tendency towards agitation of load by oscillation of the loaded conveyer belt as it passes over troughing idlers also augments the harm of excessive inclination of conveyer, so that, with the average class of material handled on such systems, it is dangerous to have the inclination of the conveyer from the horizontal greatly exceed 21 or 22 degrees—equivalent to a rise of about 36 to 37 feet per 100 feet of conveyer. With this one limitation and, of course, the disadvantage that belt conveyers cannot turn corners and must be run, therefore, in one general direc-

tion, a belt conveyer may be installed in almost any position, including horizontal, inclined, inclined with horizontal stretches of conveyer and with the belt rising in a gradual curve from a horizontal to an inclined plane. The latter arrangement is theoretically limited to the curve that would be assumed by a fully loaded belt supported only at points of tangency with the horizontal and inclined planes of the conveyer when the tension in the belt is that necessary for the satisfactory operation of the conveyer—the pull required to draw the loaded belt along at the proper speed. This curve would be a parabola, but in practice such extreme refinement of curve is not practicable and the troughing idlers for the curved section of conveyer are usually mounted so that the conveyer belt resting on them will follow the arc of a circle of about 300-foot radius. This proportion is usually satisfactory for belts of any ordinary width and the conveyer fully loaded with the average class of material usually handled by belt conveyers—the fully loaded belt will then rest on the troughing idlers, though the belt of an empty conveyer will frequently not touch them.

It is in the consumption of power that the belt conveyer has a decided advantage over the types of conveyers already discussed, and with its comparatively large carrying capacity, due to the high speed at which it can be run, when handling ordinary classes of material in bulk, it becomes one of the most valuable and economical of labor-saving devices. As in the case of any mechanical type of conveyer, power is required for three distinct operations when operating the system: 1st, for running the conveyer itself, i.e., the power required to operate the driving machinery, pull the belt over the idlers—neglecting all load other than the weight of the moving parts—etc.; 2nd, for conveying the load itself; and 3rd, for elevating the load, should the conveyer be an inclined one. The power required to pull the belt over the idlers varies with the construction of the troughing and return idlers and is naturally considerably less in conveyers with ball-bearing idlers than in conveyers employing less economical mechanisms, but this item of power is in reality but a comparatively small percentage of the total power required and when the inefficiencies and loss of power in the driving mechanisms—usually consisting of a train of gears—is taken into consideration the power requirements for running an empty conveyer really have comparatively little effect upon the total amount of power that must be supplied and may be considered with safety as bearing some definite relation to the width of the belt and the weight of the moving parts. The second demand for power, that for moving the load itself, is not so much effected by the refinements of idler construction and varies practically with the speed of the conveyer and the load handled, irrespective of size of conveyer, etc. Power necessary to elevate the load is very nearly that theoretical amount that would be required to raise the specified load through a vertical distance equal to the difference in elevation between the point at which the conveyer is loaded and the highest elevation to which the load is carried—for practical purposes, the difference in elevation between the two ends of the conveyer—as no appreciable increase in resistance to the movement of load takes place in an inclined conveyer other than the overcoming of the force of gravity. In the derivation of the following formula (Formula XIV.) conservative values for all variable factors—values obtained from numerous experiments and examination of data from a large number of efficient installations of belt conveyers—are employed and the results from its use agree very closely with the power demands for the ordinary efficient installation. Exceptional installations are found that discount this formula but the inefficiencies of the ordinary driving mechanisms make dependence on other formulæ for ascertaining horsepower requirements that give smaller results dangerous. Formula XIV. gives the total horsepower required to drive the average efficient belt conveyer when continuously and uniformly loaded to its capacity, but does not allow for the additional power requirement for trippers or fixed dumps. Such discharging devices all consume approximately the same amount of power, irrespective of load carried, and Formula XIV.-a gives values that should be allowed for each discharging device of such type for conveyers from 12 to 36 inches in width, the average range of sizes found in practice. For conveyers narrower than 12 inches, an allowance equal to that for a 12-inch conveyer should be made for each discharging device and for conveyers of over 36 inches in width the allowance for 36-inch conveyers is usually ample, unless the conveyer should be one of exceptional size. Chart III. gives the same data as Formula XIV. in a convenient form for rapid calculations and sufficiently accurate results are attainable from its use for all practical purposes.

Horsepower:

W = Weight of load handled in tons per hour (capacity).
V = Velocity (speed) of Conveyer in feet per minute.
L = Length of Conveyer in feet—distance between end pulleys.
H = Height to which load is elevated in feet (incl. Conv.)
= Difference in elevation in length of Conveyer.
w = Width of belt (Conveyer) in inches.
W′ = Weight of load handled per minute per foot of Conveyer in lbs.
= 2000 W ÷ 60 V.
W_b = Weight of moving parts of Conveyer (belt) per foot in lbs.
= 0.7425 w.
f_s = Speed factor.
= 0.004 w—from experiment.
f_l = Load factor.
= 0.080—from experiment.

Horsepower required to run Conveyer empty :—

$$= \frac{W_b \times f_s \times V \times L}{33{,}000} = \frac{0.00009\ w^2 V L}{1000}$$

Horsepower required to convey load :—

$$= \frac{W' \times f_l \times V \times L}{33{,}000} = \frac{0.08\ WL}{1000}$$

Horsepower required to elevate load :—(Inclined Conveyer)

$$= \frac{2000\ W \times V \times H}{60\ V \times 33{,}000} = \frac{WH}{1000}$$

Then, total horsepower required :—

$$HP = \frac{(0.00009\ w^2 V + 0.08\ W)L + WH}{1000} \qquad \text{Formula XIV.}$$

Additional horsepower required for each tripper or fixed dump :—

$$HP = \frac{(w-10)}{8} \qquad \text{Formula XIV-a.}$$

(Conveyers 12″ to 36″ inclusive)

Though exceedingly economical in the consumption of power, belt conveyers are expensive as far as first cost is concerned if satisfactory wear and freedom from the annoyance of break-downs are to be obtained and the true economic value of the equipment realized. That is, all apparatus should be of the highest grade; particularly the belt, which should be, as previously stated, of duck-rubber construction with a suitably thick resilient cover of rubber to withstand the abrasive wear of the load moving on its carrying surface—a certain readjustment in position of load on the belt being unavoidable in even the best designed and most carefully installed conveyers. Owing to the extreme simplicity of construction, the cost of the various component parts of a belt conveyer vary closely either with the width of the belt, as for conveyer

pulleys, drive, etc.; or with both the width and length of conveyer, as for idlers, belt, etc., and a conservatively accurate equation can be derived for ascertaining the approximate cost of any belt conveyer of given size. Such an equation follows, Formula XV., which gives the total average cost of a conveyer equipped with a high-grade rubber belt and machinery of a high class. A similar conveyer, equipped with a good grade of stitched canvas conveyer belt, would cost but about half as much and systems may be purchased for any price between these two limits, depending upon the character and quality of the conveyer belt. The best grade of belt is really the most economical, however, as a conveyer so equipped will have a much longer life than one where false economy is attempted by the purchase of an inferior belt whose depreciation is bound to be rapid. In fact, it is only with the highest grade of all equipment that the full economic value of a belt conveyer system can be realized—this point cannot be too strongly emphasized. Table VII. gives equations for ascertaining the approximate cost of the various discharging devices which are customarily employed with belt conveyer systems, all of which vary approximately directly with the width of the conveyer (belt) rather than with the capacity of the system when handling any particular class and weight of material.

Initial Cost:

C = Cost of equipment in dollars.
w = Width of Conveyer (belt) in inches.
L = Length of Conveyer in feet—distance between end pulleys.

Cost of idlers per foot of Conveyer = $0.184\ w - 0.899$
" belt " " = $0.303\ w - 1.261$
" other machinery = $4.633\ w$

$$C = (0.487\ w - 2.16)L + 4.633\ w \qquad \text{Formula XV.}$$

Table VII.—Approximate Cost of Discharging Devices for Belt Conveyers.

Apparatus	Cost in dollars
Automatic Tripper - -	$15.7833\ w + 189 + 1.13L_t$
Hand-propelled Tripper -	$9.0\ w + 106.28 + 1.13\ L_t$
Fixed Dump - - - -	$2.8\ w + 16.4$

w = width of Conveyer (belt) in inches.
L_t = Length of Tripper Track—total travel of Tripper.

Although the carrying capacity of a belt conveyer varies with the square of the width of the conveyer belt, the necessity of loading devices, discharging apparatus, etc., that varies in cost with the size of conveyer, permits the expression of the average cost of a belt conveyer system in terms of the carrying capacity of the conveyer—i.e., average carrying capacity. Such classification is not as accurate for ascertaining the approximate cost of such a system as the formula based on the width of the belt, but for purposes of arriving at the average net cost of operation of a system, where only relatively small percentages of the initial cost enter into the question, an equation for approximating the cost of equipment, expressed in terms of the average tonnage per hour capacity, is sufficiently accurate for forming a conservative calculation of the average net operating cost of the ordinary belt conveyer installation. Particularly is this so for installations where the material handled is particularly heavy and where the initial cost ascertained by such an equation would be correspondingly low, the depreciation charge is apt to be very much greater than in an ordinary installation—the two inaccuracies, as to formula, thus tend to compensate for one another and the results obtained by the use of the formula for arriving at the measure of economic value of the system is approximately correct in any case. Depreciation on all component parts of a belt conveyer are not equal, of course, but a fairly reliable average value—one for the relatively expensive belt and the other for the balance of the machinery or equipment—does exist, provided for in the derivation of Formula XVI., which permits a close calculation of the true economic value of any belt conveyer system if the cost of power is known and the system is kept in good working condition and subject to efficient operation—i.e., is used frequently, for no conveying installation can be a really efficient one if allowed to remain idle much of the time.

Net Operating Cost (N.O.C.) of Belt Conveyers:—
L = Length of Conveyer in feet—maximum distance load is carried
H = Height (distance) through which load is elevated.
W = Weight of load conveyed in tons per hour (capacity).
N = Number of hours (total) Conveyer is in use per year.

Average Cost of Equipment:—
$= 0.0904\ WL + 1.07\ W.$

Fixed Charges:—

Interest	6% total cost	$= 0.00768\ WL + 0.091\ W$
Insurance....	1%	
Taxes	2%—¾ cost	

Depreciation, renewals, etc.:—

On belt	$0.01990\ WL$
machinery	$0.00317\ WL + 0.107\ W$
Depreciation account..	$0.00025\ WL + 0.011\ W$
Total Depreciation, etc.	$0.02332\ WL + 0.118\ W$

Yearly Burden:
$= 0.031\ WL + 0.209\ W$

Horsepower, attendance, supplies, etc.:—
P_c = Price (cost) of a horsepower per hour.
Average consumption of power $= 0.00021\ WL + 0.001\ WH$

	Horizontal Conveyer	Inclined Conveyer
Cost of Power	$0.00021\ WLNP_c$	$0.001\ WHNP_c$
Attendance, etc.	$0.0000122\ WLN$	negligible
Supplies, etc. ..	$0.0000128\ WLN$	negligible

Burden depending upon use of Conveyer:—
$= (0.00021\ WP_c + 0.000025\ W)LN + 0.001\ WHNP_c$

Then:

Net Operating Cost (N.O.C.) per ton:—

$$N.O.C. = \frac{31000\ L + 209000 + (210\ P_c + 25)LN + 1000\ HNP_c}{1{,}000{,}000\ N} \qquad \text{Formula XVI.}$$

Examples.

1. Conditions:—

Length of Conveyer	100′—0″	= L
Material Elevated..	20′—0″	= H
Service.....	2400 hours per year	= N
Cost of Power	$0.02 per horsepower per hour	= P_c

$$N.O.C. = \frac{3100000 + 209000 + 7008000 + 960000}{2{,}400{,}000{,}000} = \$0.00470 \text{ per ton conv'd}$$

2. Conditions:—
The same as in the preceding example except that service is but 1200 hours per year.

$$N.O.C. = \frac{3100000 + 209000 + 3504000 + 480000}{1{,}200{,}000{,}000} = \$0.00608 \text{ per ton conv'd}$$

The typical examples cited well indicate the real value of the belt conveyer as a means of transferring material from place to place, as the conditions assumed are very frequently found in practice. An interesting point is brought out by these examples, namely, that a belt conveyer is much more economical if in continual use than if used only occasionally. This is due to the facts that the system is very economical in the consumption of power, that the expense for attendance or labor is low when charged to actual tonnage handled, and that supplies, such as waste, lubricants, etc., are also low, while the burden of interest on investment, taxes, insurance, etc., is relatively high and is constant, no matter how frequently the conveyer is used. The burden of depreciation which is charged as the same in the two examples and so proportioned in Formula XVI., does not depend upon the hours of operation—provided, of course, that the conveyer

is in use a fair number of hours each year—as depreciation is almost as rapid in an idle conveyer as in one that is in continual use, for proper attention and care is rarely accorded the equipment unless it is in actual service. In fact, unless the conveyer belt is carefully cleaned, removed from the conveyer and stored in a place of even temperature, free from acid, hydro-carbonaceous fumes,

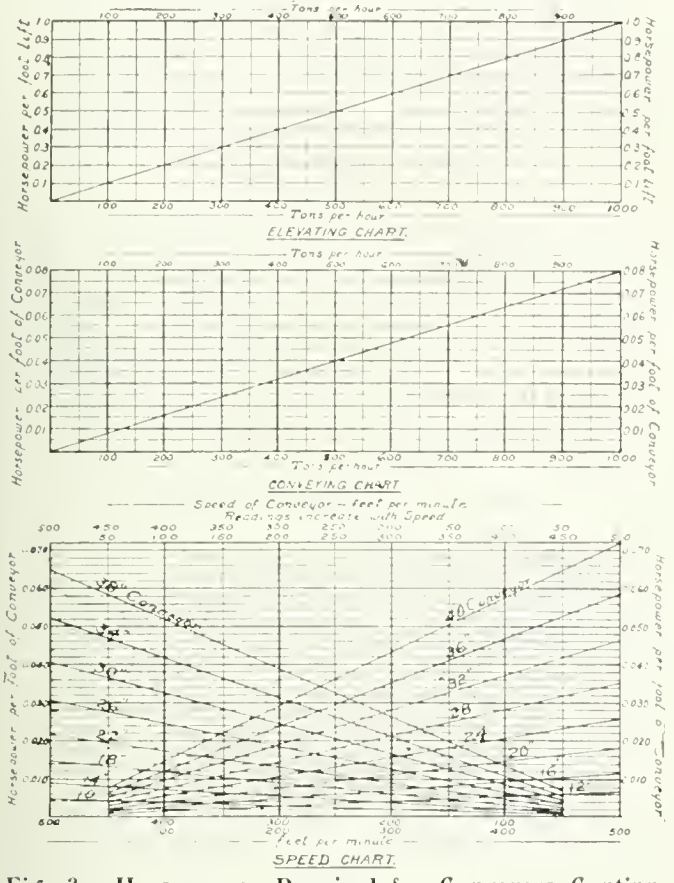

Fig. 3.—Horse-power Required for Conveyers Continuously and Uniformly Loaded.

Note.—To ascertain total horsepower required, multiply the sum of Speed Chart and Conveying Chart readings by total length of Conveyer in feet and add the Elevating Chart reading multiplied by total lift in feet. For each discharging device add an additional 1/8 horsepower for each inch of Conveyer (belt) in excess of 10 inches.

moisture, etc., etc., its deterioration may be even more rapid than if actually used for carrying material for, in use, particles of the load have a tendency to stick to the belt and to protect it from the injurious effects of many agents. This all emphasizes the economic fact that the more economic a piece of apparatus the greater the necessity of its continual use in order to realize the maximum benefits.

In this discussion, no attempt has been made to indicate the wide use to which belt conveyers may be put, such as picking conveyers for the sorting of ores, etc., the handling of mail in post offices, packages in department shops, cements in bags, etc., etc., but the discussion has been limited rather to one of conveyers for handling material in bulk. The laws and rules that have been laid down, however, can easily be modified to meet almost any condition of service, for the power consumption of belt conveyers depends almost entirely upon the load carried, distance of transfer, and inclination of conveyer. The question of width of conveyer (size) has little effect upon the consumption of power. Initial cost, on the other hand, really depends almost entirely upon the size of the conveyer so that only a modification of the various formulæ that have been given need be made to fit almost any special use of belt conveyers. Reference will also be made to this class of conveyer when describing certain special installations and operations, for such equipment is found in almost any modern enterprise.

THE CANADIAN LOCOMOTIVE COMPANY'S NEW PLANT.

An idea of the radically different layout of shops at the Canadian Locomotive Company's plant, at Kingston, Ont., as at present being changed, may be gathered from the accompanying plan. On the completion of the buildings there shown, the whole plant will be essentially new, as while three of the buildings are shown as being old, the only one of these three that goes back ten years is the machine shop to the right, completed some few years ago. The power house has only been in operation about eight years, and the boiler shop is less than two years old, so that with the new shops, the plant will be almost entirely new throughout, replacing the antiquated buildings with which the company has heretofore been compelled to do business.

The whole area shown in the plan has been more or less covered with a miscellaneous collection of old stone buildings, scarcely adapted to the work done, except under adverse conditions of operation. The problem presented was that of removing these old buildings, and re-

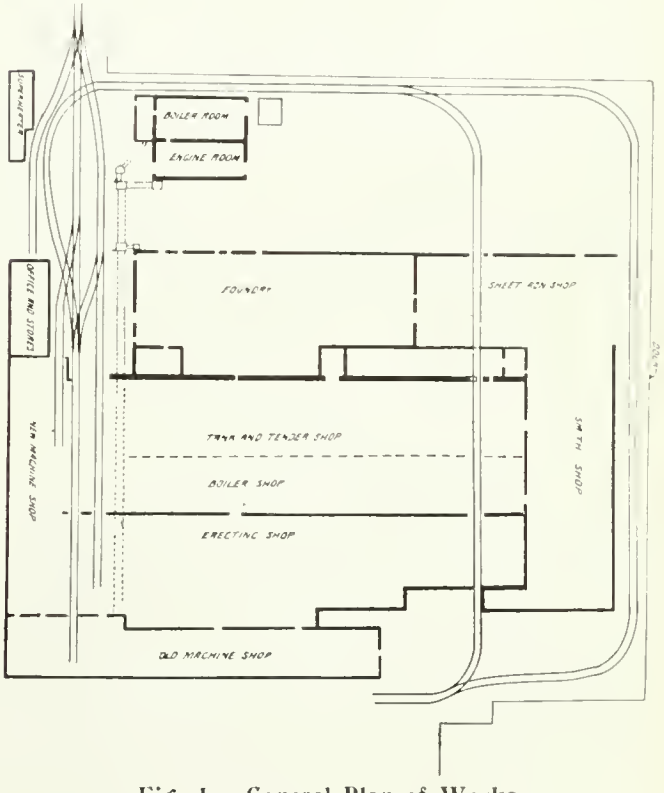

Fig. 1.—General Plan of Works.

placing them with newer ones without interfering with the locomotive construction work. This is being accomplished by razing the old buildings one at a time, and on the cleared site, erecting the new ones.

The work of reconstruction was first commenced on the buildings to the north of the old boiler shop, erecting the new tank and tender shop on ground unoccupied, and then tearing down the old tender shop for the erection of

the new foundry and yard runways on the site of same. Following this, the old foundry has been torn down, and on its site a portion of the new erection shop is now being erected.

Fig. 2 shows an interior view of the centre bay of the foundry, which is used for moulding all heavy parts. The building has a high monitor with continuous sash operating the whole length, so that all smoke and gases can find an easy exit.

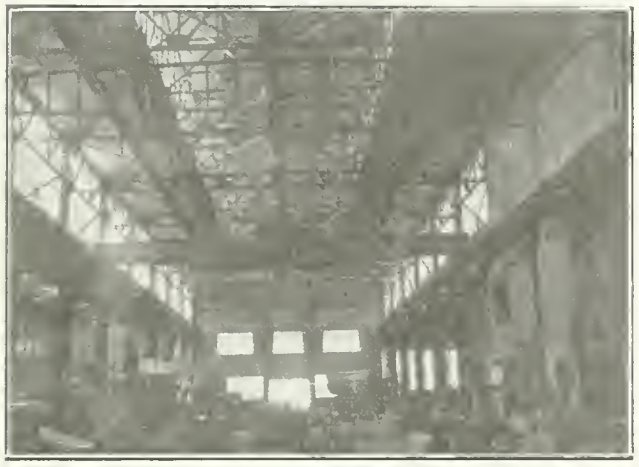

Fig. 2.—View of Centre Bay of Foundry.

A cross-section of the new erecting shop is shown in Fig. 3. This has a centre bay 80 feet wide with a 200-ton travelling crane for lifting locomotives and a 20-ton travelling crane below it. There will be fifteen erecting pits running crosswise, spaced at 17-foot centres, in this shop when completed. This shop has two side bays with galleries in which will be located pipe shop, superheater shop, paint shop and electrical departments. The main bay opens directly into the new machine shop, and runs at right angles to same, while the 20-ton crane in the erecting shop runs 20 feet into the machine shop, so as to deliver heavy material directly to engines there being erected. The new machine shop will also be served by a 20-ton travelling crane.

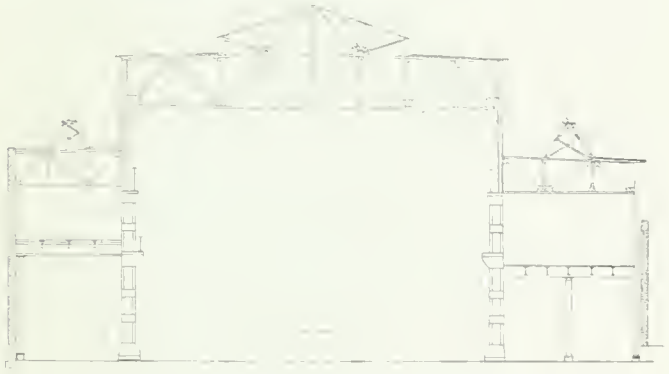

Fig. 3.—Cross-Section Through Erecting Shop.

A carpenter and pattern shop with pattern storage is being erected on a new site. As soon as these are completed the present carpenter shop, located at the south end of the old boiler shop and new tank and tender shop, will be torn down to provide space for a new blacksmith and hammer shop to be erected on this site. Following this, the old blacksmith shop will be razed and an addition to the new erecting shop and the old boiler shop will be built.

After these buildings are completed the old erecting shop and stores and office building running on Ontario Street will be demolished, and on this site a new four-story reinforced concrete store and office building, and a new machine shop will be built.

The convenience of the layout is at once apparent. Every building will be in open communication with all the others. In addition, it will be noted that the focal point of construction is the erecting shop, about which every building in the plant is arranged, all the parts feeding directly into that final point.

The total area of the plant covers about 9.5 acres and 7.5 acres of this will be covered by buildings.

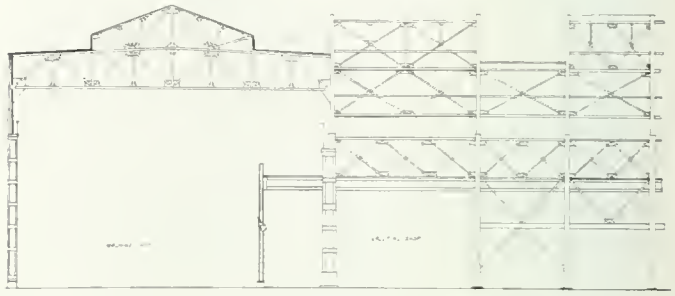

Fig. 4.—Cross-Section Through Machine Shop.

The general design of these buildings has been worked out by the firm of Henry Goldmark, consulting engineers, New York; all details regarding buildings and their equipment, and the construction work, have been carried out under the personal supervision of C. J. Goldmark, of that firm.

RAILWAY CARS OF STEEL.

Apparently acting upon the idea that collisions cannot be avoided, the different railroad companies are considering the advantages that will follow the introducing of all-steel cars in their rolling stock equipment. While one might suppose that this change would add largely to the element of cost, it is a fact that the outlay per passenger carried for the two styles of cars is about the same.

This practical identity of cost is due to the fact that although steel cars cost $17,000 each and wooden cars only $9,000 each, the former cars are seventy feet long and the latter only fifty-four feet, and there is a further advantage in favor of the steel construction by reason of greater durability. Of course, the two main points in favor of steel cars are that they do not crumple up after the shock of a collision and they do not burn in the event of the always possible and usually probable fire.

It is now generally recognized that if the Bar Harbor Express had been made up of steel cars exclusively at the time of the North Haven disaster, there would have been no lives lost. Just how steel cars behave under such conditions is shown by the experience of a collision in Pennsylvania early in the present year, when a passenger train going thirty-five miles an hour crashed into another standing still and no one was injured.

Of course, from the railroad point of view, the main question is, How does the steel construction affect the question of cost? At first it was thought that the saving in maintenance on the new style cars over the wooden ones would take care of interest on the larger investment. This has not yet been achieved, but it is being closely approached as the railroads discover and remedy the faults of the first steel cars delivered.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of,
CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, RAILROAD, MINING, MUNICIPAL HYDRAULIC, HIGHWAY AND CONSULTING ENGINEERS, SURVEYORS, WATERWORKS SUPERINTENDENTS AND ENGINEERING-CONTRACTORS.

Present Terms of Subscription, payable in advance.
Postpaid to any address in the Postal Union:

One Year	Six Months	Three Months
$3.00 (12s.)	$1.75 (7s).	$1.00 (4s.)

THE VALUE OF ENGINEERING TRAINING.

The resumption of technical instruction in the universities this week brings into touch with engineering courses a large and increasing number of men, among whom will be engineers of the future. The fact that engineering, although one of the oldest of the arts, has only within the past generation or two become generally recognized among the learned professions, makes it somewhat difficult for the student in engineering to choose between the courses which the calendar presents. There are no regulations existing such as are common to the oldest and most widely recognized professions, the scope and prospects of which are generally well defined. The field of engineering has broadened so much during the past twenty-five years that it is no longer possible to say just what it includes or excludes. It has no hard and fast lines of limitation, nor yet are the lines of division between its various branches quite distinct.

In the case of the three more important branches, viz., civil, mechanical and electrical, into which it has been frequently found convenient to roughly sub-divide the scope of the profession, there is often a considerable amount of overlapping, especially in the case with mechanical and electrical engineering. The boundary line is very indistinct, and it is difficult to say to which branch of the science many phases of development work belong. For instance, the mere replacement of a steam engine by an electric motor to drive the main shafting of a plant can hardly be called a piece of electrical engineering; but if special electric appliances are introduced to perform duties which cannot be done, or not done as well, by purely mechanical machinery, we have electrical engineering in the true sense of the term. The two branches are in many respects, upon the same general footing, nevertheless, and the majority of principles upon which the university courses are based, apply equally to both branches.

It will be readily noted, however, that while mechanical and electrical engineering have much in common they differ entirely from civil engineering. In this branch every new undertaking of any magnitude involves entirely new conditions, and introduces unforeseen problems, each of which may have to be approached with little precedent for guidance.

Opinion in the past has been very divided as to the best lines on which engineering training should be carried out. Formerly a purely practical training was preferred, leaving the young engineer to pick for himself such knowledge as he was able, of the science underlying his profession. With its expansion, and the rapid application of technical science, theoretical training has been brought to the fore, more or less at the expense of practical training. At the present time engineering authorities are fairly well in unison concerning the advisability of alternate periods of technical and practical training, although opinions differ as to arrangement of the courses

This policy also applies with force to the other branches of the engineering profession. Its importance is such that a man who is beginning a course in engineering should be conversant with the general evolution of the nature of the training which he hopes to acquire. From a knowledge of its history the necessity will present itself to him of keeping always in mind the fact that the university course does not turn him out an engineer; but that by the practical application of the principles which he acquires thereby he may be better enabled to become an engineer.

CANADIAN ENGINEERS AND ROAD CONVENTIONS.

That for years to come highway problems will occupy a most prominent place in Canadian municipal affairs is a potent reason why our road engineers should take cognizance of the road conventions that are being held within attending distance. The American Road Congress in Detroit this week has gathered from far and near the pioneers of scientific road construction in America, and their views and experiences as related in the discussions following the numerous papers presented, cannot be surpassed in value as enlightenment on the many factors upon which such work is contingent.

Another convention that should receive the attention of our men in highway engineering is that of the American Road Builders' Association, to be held in Philadelphia in December. A tentative programme of this Good Roads Congress appears in another column, and further information respecting the plans for it will be published shortly.

The Ontario Good Roads Association passed a resolution worthy of note last week, deciding to extend to the American Road Builders' Association an invitation to hold its 1914 convention in Toronto. The invitation will be delivered in person by the president and secretary at the coming convention in Philadelphia.

If it meets with acceptance, Canada should at once prepare to show the American Road Builders' Association the immensity of the Canadian road problem, coupling with it a well-defined policy showing how its many difficulties are to be overcome.

Canada's road problem is merely a revised version of the same questions that have been before the highway officials of other countries, and that, in many instances, are still pending solution. Chief among the influences retarding a settlement by standardization of road construction has been the introduction of faster and heavier vehicles. Practically all countries are of an opinion concerning the certainty of the change which methods of road construction must shortly undergo, to meet the motor-driven vehicle as a successor to the steel-tired horse-drawn vehicle. More up-to-date systems of road engineering must be adopted if the expense of maintenance is not to become excessive.

But until the battle for supremacy between the new and the old has been fought to such a stage that the engineer may be justified in practically eliminating one of them from consideration, there will be no standard road or pavement. Before the advent of the automobile there was a single class of traffic, varying only in intensity. Since then motor-driven vehicles equipped with rubber tires have destroyed the old standard construction to such an extent that ordinary macadam is not likely to regain the place it held as a satisfactory type of road for general use.

Thus the problem has resolved itself into a selection, for each particular piece of road, of the type that will serve local conditions best. This requires a highway engineer to have a very comprehensive knowledge of the characteristics of all pavements in use, since there is no standard for his guidance.

Such considerations as these should emphasize the advantages to be derived from a participation in the proceedings of the road conventions.

RE PROPOSED CANADIAN INSTITUTION OF MUNICIPAL ENGINEERS.

An informal meeting of the engineers attending the Canadian Public Health Convention at Regina was held on Friday, September 19th, to discuss the question of forming a Canadian Institution of Municipal Engineers.

Mr. Wynne-Roberts (Regina), the convenor, submitted the correspondence which he had with several engineers, the great majority of whom approved of the idea. Letters had been received from city engineers located in many parts of the Dominion. Those from Toronto and Winnipeg were not favorable, but those from Edmonton, Regina, Battleford, Vancouver, London, New Westminster, Calgary, St. John, N.B., Halifax, Ottawa, Fort William, St. Catharines, Glace Bay, C.B., Peterborough, Guelph, Sydney, N.B., and Hamilton were favorable. Some desired more information. Representatives from Battleford, Saskatoon, Prince Albert, Swift Current and Toronto, who had not already written expressing their views, were present and verbally stated their opinions.

After fully discussing the matter from various viewpoints, it was unanimously resolved: "That this meeting of the engineers present at the Annual Convention of the Canadian Public Health Association, held in Regina, after considering the question and perusing the letters received from city engineers in various parts of Canada, is of the opinion that it is desirable to form a Canadian Institution of Municipal Engineers, and that a Provisional Committee be appointed to enquire into and adopt the most advisable steps for its formation." The names of the committee members will be published later on, after their individual consent to act has been obtained.

EDITORIAL COMMENT.

If properly carried out, Calgary's intention of planning street grading to meet requirements of several years to come, so as to keep well ahead of civic improvements, will save the city a lot of money. This desirable policy will enable the laying of water-mains, sewers and street paving to be executed without apprehension of early subsequent disturbance, and it will also obviate alterations to residential property occasioned by the cutting down of grades, in connection with pavement work. The city requires much grading work to be done in places, and the step which the City Commissioners are taking is a matter of great permanent importance to property holders in particular, and the citizens generally.

Especially in the case of street pavements, we hear so much of their disturbance for the laying of water-mains, etc., that the plan which Calgary purposes to follow should be considered by every city and town in Canada, and it seems practicable enough to be continued if once established.

CORRECTION.

In Mr. V. J. Elmont's paper in last week's issue, the table on page 486 is not explicit without further explanation. The bending moment values are arranged vertically under the different values of $\frac{x}{l}$ and horizontally opposite the different values of $\frac{y}{l}$. In the table also, "o.x" simply means "o."

THE CHEMICAL AND BIOLOGICAL EFFECT OF WATER FILTRATION

ORGANISMS IN EARTH AND WATER AND THEIR FUNCTIONS—EFFORTS TO ELIMINATE PATHOGENIC BACTERIA IN WATER BY FILTRATION—THE FILTER FILM AND ITS WORK—AUXILIARY CHEMICAL TREATMENT—EXTREME PURIFICATION DANGEROUS

By H. W. COWAN,
Chief Engineer, Bell Filtration Co. of Canada, Limited.

MUCH argument has taken place as to whether bacteria are a form of plant or animal life. One of the lowest forms of plant life, known to the botanical microscopist as oscillariae, possesses similar characteristics to the types of organisms called bacteria.

The chief difference is the presence of chlorophyll in oscillariae, or the green coloring matter which enables the plant to derive nourishment from such simple foods as it can procure from the air and soil, in which it is present. It is the absence of chlorophyll in bacteria which forces them to live on more complex foods. Both have the power of motility, the same form, the same method of thread and spore formation, and may both be considered as true plants.

The simplest forms are typical of bacteria, spherical, cylindrical or spiral. They are so minute that their diameters range from 0.000012 to 0.0003 inches. A coating of some gelatinous membrane seems to envelop most species, serving as a cement to keep them together. Their internal structure of protoplasm has never been definitely decided on, and is still much a matter of conjecture.

When massed into clusters bacteria are known as zoogloea, which differ from a colony in that the latter is formed when a single bacterium is cultivated in some mass which presents too much resistance for the separation of the bacteria to any distance. Varying species form different characteristics in their colonies, which serve as a means of identification when under examination.

Bacteria multiply very rapidly, unless in unsuitable conditions, by the simple process of dividing in two, a process which can go on indefinitely until as many as 16,000,000 are produced in twenty-four hours. In addition to this simple method of propagation, some species produce spores. These are round or oval pieces of bacteria protoplasm, which develop until they finally break out of the original organism. When the original germ cannot exist, the spores are still to be found resisting very adverse conditions, and acting as a means of perpetuating the species.

A means of motility is supplied to many species, which have stringy membranes attached to them, sometimes one, two, or many, sometimes at one end, and sometimes at both. By lashing these membranes back and forward, a means of propulsion is supplied, which is very active when the germs are immersed in liquids.

The food of bacterial organisms is secured from the dead bodies of animals or plants, and their excretions, which they rapidly decompose in their operations for assimilation. Probably the rapidity of multiplication is due to not having to manufacture food, as in the case of other plants. In effecting the decomposition of substances, many chemical and physical changes are wrought, extensively made use of in the maceration industries.

The manufacture of linen, jute, hemp, fibre, leather, sponges, and the products of fermentation, is chiefly dependent on the action of various forms of bacterial life. In still more important functions are bacteria necessary for the continuity of life, and the preservation of mankind. For the purpose of showing this some digression is allowable for consideration of other plants and their mode of existence.

No life could exist if the earth were littered with dead matter, but bacteria, acting as scavengers, and putrefactive changes prevent such a happening. The earth's surface has been the producer of the countless years of life. Plant life has extracted food from its soil and air without apparently diminishing the food supply.

The animal kingdom breathes oxygen and exhales it as carbon dioxide, which the vegetable kingdom inhales and returns as free oxygen to complete the cycle. Plants also consume nitrogenous food from the soil, in the form of nitrates, in combination with gaseous products of the air and other elements. These solar energy transforms into starches, proteids, sugars, fats, etc., to supply animal life with nutrition.

Carbonic acid and water are returned by the animal in the assimilation of its food, to be again absorbed by plant life, but nitrogenous food is not returned in total. Most of the nitrogen consumed by animal life is turned into albumens and the balance excreted. Even when the animal dies, the nitrogen is too complex in its compounds to form plant food, when recovered by disintegration.

The bacteria of decomposition and putrefaction now set to work to reduce most of the nitrogen compounds into suitable feeding material for the plant, leaving the balance as nitrites, which in turn are too simple for plant food.

The soil abounds with organisms called nitrifying bacteria which unite these nitrites with oxygen and transpose them into the nitrates necessary for the existence of the vegetable world. In decomposing, dead animal life frees a proportion of nitrogen which passes into the air, thus reducing the supply of nitrogenous food returned to the soil. More is lost in excretions taken direct to the sea in the form of sewage, while many of the chemicals used in the manufacture of explosives and other articles of commerce consume a large amount.

The farmer makes up this deficiency by the application of chemical fertilizers to the ground, but were the same soil freed from all plant life, and exposed to the air

for a period, nitrogen fixation would be secured through the activity of bacteria in the earth. Not only in this way is dispersed nitrogen recovered, but also by an active co-operation of germ life with certain leguminous plants. These organisms attach themselves in globules or clusters to the roots of the vegetables, and with both agencies at work some nitrogen is fixed in the fibrous structure of the legume. Disintegration and rotting of the plant enables the stored-up nitrogen to be fixed in the soil.

In the scheme of life, therefore, bacteria have very important and definite functions to perform. Without them the recovery of nitrogen for plant food would be impossible, and the circle of life created by the energy of heat would cease. Were it possible to destroy germ life as a whole, the result would be the total extinction of all forms of life.

There are, however, other types of bacteria which are pathogenic, and have the power of reproduction in the human body, causing many diseases to which humanity is subject. The proportion of these to the harmless bacteria is fortunately small, but as they give rise to such sickness as typhoid, cholera, diphtheria, tuberculosis, lock-jaw, anthrax, influenza, etc., they must be kept down. These germs produce by-products which act as virulent poisons to the human system, causing the diseases enumerated together with many others. They gain access through the mouth, nostrils, cuts and breaks in the skin, and set about reproduction by incubation until the disease gets a hold on the body. If the powers of resistance of the body are very great, the organisms are disposed of, and the sickness is warded off. These resistive forces are not yet fully known, but science has established the presence of certain products in the body termed alexines which kill non-pathogenic germs. To combat the alexines the pathogenic bacteria create lysines to neutralize their action, and make the way clear for their depredations.

The invading bacteria are then attacked by the white corpuscles of the blood, which leave their usual habitation in the blood vessels and surround the attacking germs. The evidence of this is generally given by the appearance of inflammations, either internal or external, which break out and give off pus should the corpuscles be vanquished. With such contending influences in the body, disease is warded off by those in robust health, and the importance of maintaining these resistive powers cannot be over-estimated, otherwise they will become useless through dissuetude.

The chief means of conveying the harmful bacteria to the body is by means of liquids which act as carrying agents in a greater degree than any other source. In consequence, our drinking water supplies are of national importance, and the elimination of harmful or pathogenic germs from them is the first essential to disease prevention.

Methods of Filtration.—The methods of filtration generally employed are to filter all water used for drinking purposes by means of sand filters, of which there are three distinct types—slow sand, gravity mechanical, and pressure mechanical. Of these the first and last are most commonly used in the older countries, while on the American continent the first and second are favored. In the slow sand filter the water is allowed to flow through beds of sand and gravel, into collecting pipes placed under the filtering material, at rates varying from one to six million gallons per day. They are generally constructed of brick and concrete, or both, and occupy a large area. Gravity mechanical filters are frequently constructed of the same materials, or of wood or steel, containing sand overlying gravel, while pressure filters are entirely composed of steel. Both of these latter types operate at rates up to one hundred and seventy-five million gallons per day. The ratings given are for an area of one acre.

Before the sand in all types of filters performs effective work, it must be coated with a film which retains the bacteria in the passage of the water through the filter. The slow sand filter forms this filter naturally by the growth of vegetation, the deposit of fine clay particles, and the agglomeration of organisms. In the mechanical type the film is deposited by the addition of alum to the water, before it is applied to the sand bed. The alum reacts with the lime in the water, or with added lime if the water is deficient, and forms a gel or albuminous coagulant which is insoluble, and deposits on the sand bed.

In course of time this film becomes too impervious, and it is necessary to clean the surface of the filter to allow the water to find its way through. In the slow sand filter this is performed by scraping off the surface to a depth of about ⅞ of an inch, and passing through a sand washer to make it ready for replacing when the sand bed gets too shallow to work satisfactorily. In the gravity mechanical and the pressure mechanical filters cleaning is carried out by the operation of valves to force the water back through the sand bed, where it is run to waste. Agitation is performed by means of compressed air or mechanical means to break up the sand, so that the reverse flow of water may do its work.

In the slow sand and gravity mechanical types of filters, water flows in by gravity or is raised by a pump, and allowed to flow through the filter under atmospheric pressure only, into a clear water reservoir from which the filtered water is pumped to the service pipes. In the pressure type of filter the water is forced through by means of a pump, or sufficient height of water to supply an equivalent pressure. The pressure filter is totally enclosed, while the other types are open.

It does not fall within the scope of this paper to enlarge on the merits of any particular type, beyond saying that with a properly designed plant and proper operation, they should all give equally high bacterial reduction. On leaving the filters it is common practice on this continent to treat the effluent with chlorine to further reduce the bacteria content, and approach as nearly as possible a sterile water. With this practice the writer is not at all inclined to agree.

Chemistry of Filtration.—It is well known that the work performed by sand filters is to remove suspended solids, and to act in such a way that both chemical and biological changes are wrought in the treated water. In considering the presence of dissolved substances in the water, it is found that chlorides do not vary much, neither increasing or diminishing in passing through the filters. Nitrates vary either to a greater or lesser extent, and sulphates and carbonates remain pretty much the same. In both slow sand and mechanical filters, the chlorine content, as indicated by the presence of chlorides, seldom varies, while in both cases the carbonates are reduced about one grain per gallon. Albuminoid ammonia is reduced by mechanical filters from 15 to 90%, according to the water treated, and an average of about 60% in the case of slow sand filters.

Free or saline ammonia is reduced from 33 to 50%, and sometimes as high as 95%, in mechanical and slow sand filters respectively. The oxygen absorbed varies

from 50 to 90% reduction with mechanical filters, as against 40 to 50% with slow sand filters.

Mechanical filters reduce nitrates and nitrites from 5 to 60%, while the slow sand filter ranges from 10 to 30%. Before discussing how these changes may be brought about by filtration, it is interesting to note that mechanical filters are much more uniform in their results than slow sand filters in the reduction of albuminoid ammonia. In three months' observation of tests made every third day, while the raw water content varied from .002 to .0067 grains per gallon, the effluent only varied in its quantity from .002 to .00265 in one series of tests. Another series during the same period, showed the variation from .003 to .0039, with the raw water containing from .0046 to .0067 grains per gallon. At the same time tests were made with slow sand filters treating the same water, in which albuminoid ammonia was present in quantities of .0063 to .0064 grains per gallon, the effluent varied from .0035 to .0059 grains per gallon. The mechanical filters, therefore, while treating water with considerable variation in quantity of albuminoid ammonia, contained practically the same amount in the effluent. In the slow sand tests the results were just the reverse, and laboratory practice further accentuates the difference.

In mechanical filters, sulphates increase from one-half to one grain per gallon, due to the addition of alum which dissociates sulphuric acid in hydration.

The presence of chlorides, unless they can be accounted for by proximity to the sea, or natural salt deposits, gives an indication of sewage pollution of the water supply. Before the advent of bacteriology, nitrates were used to determine the standard of purity, but their presence is no longer considered except to call for confirmation of sewage pollution by bacterial tests. Water high in nitrites, however, should be condemned, until exhaustive tests have been made and their source accounted for. More free ammonia than albuminoid ammonia is a sure indication of the presence of polluting matters, as in normal waters the albuminoid at least equals free ammonia. If such oxygen is consumed in testing, the probability is that pollution has occurred unless with waters high in color, where the original oxygen has been depleted in oxidizing the vegetation.

Bacterial reduction in all filters of the types mentioned, operated on the same water with the same care, and with suitable rates of filtration, with suitable water for all types, should be much the same, ranging from 85 to 100%, according to the count of bacteria in the untreated water.

The Filter Film.—In performing these changes consideration must be given to the nature of the film on the sand, and its action, so that we may be able to judge what is most likely to give constant results when dealing with any particular type of water. The film on the slow sand filter is composed of fine particles of clay and mud, of green and blue algae, fungus, bacteria, etc., which very soon propagate under favorable conditions when the water contains the original propagators. The bacterial bodies present mass themselves in zoogloea, or into colonies, and putrefactive changes in many of the diatoms produce slimy brownish masses of matter. These form a net-work over the surface of the sand, which is bound together by the active diatoms, and the whole mass coheres and feeds on other organisms, or the same placed thereon in the act of filtering. At the same time there is constant destruction going on in the film, between opposing plants, which is the primary cause of the expert attention required in the care of slow sand filters, so that the film may be guarded against rupture. Algae has quite a purifying action in the removal of bacteria, without the assistance of other diatoms, and performs useful functions in the purification of stored waters.

The whole of this mass is of a gelatinous, viscid, and sticky nature, eminently suitable for adhesion of particles coming in contact with it. Each particle of sand on the upper layers of the filter becomes wrapped in a coating of the sticky substance, and a drop of water flowing around that particle will leave any minute organisms sticking to the coating on the sand, to be sucked in and retained, if not disturbed by vibration or variations of flow in the passage of the water.

The vegetation in this film is suited to the action of nitrifying bacteria, which transform the ammonia content of the raw water into nitrates and nitrites, reducing the ammonia and increasing the nitrogen. Where a reduction of one is shown, without an increase of the other, the ammonia content has been very small, in other cases there may be sufficient ammonia present in organic matters in the water for the nitrogen to show an increase not wholly due to transformation of ammonia products into nitrogenous from the water.

Albuminoid ammonia, on the other hand, forms food for many forms of bacteria, which transform it into various fatty compounds, gases, and water. Decomposition again sets in, and nitrates, ammonia, carbonic acid and water are the final products. Thus we can readily see that the feeding stuffs necessary to the life of bacteria on the sand bed, are drawn from the water, with the consequent reduction of these food stuffs after the water is filtered.

In the film formed in mechanical filters the work performed appears to be mostly of an absorptive nature, the deposit being more like a membrane full of minute cells, which are closed, and present a very large surface when wrapping round the particles of sand on the upper layers of the filter. These minute cells of the gel are continuously opening and closing, giving up the necessary amount of water each time to equalize the vapor pressure with the surrounding fluid. It has been found that by removing the water from colloidal substances, various chemical compounds holding varying amounts of water are not formed in cycles, but that the water content changes continuously. Thus the coagulation of a hydrate makes a kind of tissue, neither solid or liquid, which encloses liquid. With this construction it may readily be understood that the enclosed water in the cells may, in being replaced by other water containing a minute organism, leave the organism in the sticky cell, when it opens to allow of the absorption of a fresh quantity of liquid.

Heat is destructive of the adsorptive properties of the gel membrane, probably by contracting or stretching the formation until the cells collapse into a flat plane. The great surface tension of the culloid and the pulsation movement of the innumerable cells, in the opening and closing, explain the suction-like action of the firm in drawing in gelatinous or minute substances, while its viscosity and stickiness aid in the retention of these foreign matters.

Every weathering process in nature is productive of some form of gel in regard to its minerals, stalactitic, botryoidal, or glassy in form, with fibrous fractures, sometimes being found even in a gelatinous state. The filtering action of nature in well waters and successful infiltrations is probably due to the action of these gels. Their absence in some vicinities certainly accounts for the

failure of similar constructions, when these are apparently exactly the same, but in a locality with a totally different mineral deposit.

Biological and Aesthetic Considerations.—In common with the changes caused chemically and bacterially, there are many other biological changes desirable for the securing of the more aesthetic qualities of a water supply, such as color, taste, and odor. The mechanical filter is highly successful in treating waters which have to be dealt with in regard to these qualities. The slow sand filter rarely removes more than 20% of the color, while with the mechanical filter total elimination is possible. Odors which are caused by decomposition of vegetable matter are rarely disagreeable, but living organisms, or vegetation may also cause them. Many forms of bacterial or organic growth give off matters of an oily nature, which have a smell peculiar to the species from which they are exuded, in a way analogous to the poisons given off in the body by pathogenic bacteria.

Agitation may break up these bubbles of oil and spread them through the water until the odor is accentuated. In the same way heat, when applied, scatters the oily products and exaggerates the odor until it can be definitely compared with others known to the physical sense. The number of such organisms present in the raw water determine the intensity of the odor, and the various intensities may make the smells appear different, while they are really produced by the same organism.

It is possible that the substances producing the aforementioned qualities may have a poisonous effect on the human system, but unfortunately science has not yet been successful in demonstrating this.

Odors of decomposition are usually set up in the water pipes of a system, by the action of the filaments of plant life attaching themselves to the inside of the walls, propagating there, then becoming detached when in a state of partial decomposition. This is the frequent cause of pitted pipes, as the preservative coating is detached along with the organism, allowing rust to set in. Every system should be flushed out completely and thoroughly, periodically, as a safeguard to the preserving of the pipes against such action, and the maintaining of the physical qualities of the water at the highest standard.

Color is entirely the result of dissolved vegetable matter, and is, therefore, generally associated with taste or odor produced by the same substances. The oxygen used in the oxidizing of the vegetation in solution sometimes gives an insipid taste to the water, which is simply removed by aeration, to replace the occluded oxygen.

In the removal of odors due to organisms, filtration is effective, while the absorptive tendencies of coagulants collect the globules of oil, together with the organisms producing them. Products of decomposition are retained in the same manner, and those growths which attach themselves to the piping in the water system are prevented from passing into the supply. They cannot then become nauseating by detachment.

Nature has been copied as closely as possible in the filtration of public water supplies, and the results of slow sand and mechanical filters are practically the same as those performed naturally.

Auxiliary Chemical Treatment.—When water is too soft, it frequently sets up an acid reaction, particularly in the case of peat discolored supplies, which has the effect of dissolving the piping through which it is conveyed. This brings about lead poisoning to the consumer. The absence of mineral salts is a plausible cause of rickets and bone weakness.

Waters which are very hard may also be productive of plumbo solvency when they give an acid reaction, and are frequent causes of constipation and troubles of the digestive organs.

Extreme hardness leads to a stunted and ossified growth in individuals, as is well instanced in the Cretins, a race of dwarfed people who live near the Swiss borders, and use very hard waters.

The commercial side is also important, as the extra cost of fuel with hard waters, and the high cost of soap to a community is very burdensome.

With such waters hardening should take place prior to filtration, or softening where necessary, by the addition of lime water to increase hardness, or an excess to reduce the same trouble.

Danger in Extreme Purification.—A note of warning might well be sounded before attempting to exceed the results produced by natural means, as in the tendency in Canada at the present time.

The exigencies of modern civilization demand the collection of human beings in congested sites for the pursuit of industry. The consequent polluting of water supplies, with the subsequent necessity for treating them follows.

In the old tribal times there were no large communities gathered together for a long period of time. The people were constantly moving from one camping ground to another, and oxidation had time to effect purification after a site had been deserted. The spread of disease was to a great extent safeguarded by the absence of a means of conveyance in the shape of water systems, public vehicles, etc., and the water supply was carefully guarded from pollution by those in the camp using them. The dread intestinal diseases of bacterial origin were not much heard of until the commencement of the industrial era, and most of the scourges which attacked communities were of a zymotic nature rather than an intestinal.

Is there not a possibility that attempts to purify our drinking supplies are being carried too far? Would it not be wise to determine what is the maximum extent to which it is safe to go?

The healthiest communities are those with natural water supplies, often carrying a large bacteria count of harmless germs, with a small proportion of mineral salts. Yet, modern demands cry out for sterilized drinking water. Even distilled water, devoid of all natural salts, is being largely consumed, while recent investigations into the large number of tubercular patients in navies using distilled water exclusively, point to the demineralization of the human system as conducive to the inroads of the tubercular germ. Much interest will be shown in the experiments now being conducted by French scientists to prove that the absence of mineral salts in drinking waters is a forerunner of the wasting disease.

An attempt has been made to show the vast importance of bacteria in the great scheme of existence. Are we not eliminating some of the bacteria which an all-seeing Providence has provided for the performance of vital functions in the body?

Professor Metchinkoff, in one of the most interesting and masterly treatises of modern times, in summing up the results of his investigations into the longevity of a certain European race, demonstrates clearly that the scouring action of bacteria present in their national beverage of sour milk is probably the reason for the felicity obtained by that people.

In our food and drinking supplies, water conveys bacteria directly from the soil, other bacteria are deposit-

ed after cooking by touch, from the air, and by contact, while fruit is mostly removed from its peel or skin, and therefore from the greater part of its bacterial life. Useful bacteria can therefore have drinking water as a possible conveyer only.

It is not known what action harmless germs have on the human body, and the body's curative agents have power to combat the inroads of harmful bacteria, when their numbers are not too great. As the proportion of harmful bacteria to harmless is small, an efficient filter removing about 98% of the total bacteria count in drinking water can leave few, if any, pathogenic germs to play havoc with the consumer. Even the few which might escape will perform good work in providing exercise for the resistive forces of the body, and preventing their becoming defunct through dissuetude.

Potable waters in Canada after filtration are invariably treated by chlorine as an additional preventive, with the tendency to produce bacterial sterility. This has been brought about by the use of filters whose operation is not all that can be desired, and is a slur on the engineering profession generally, which may have very far-reaching consequences. There are filters which can be relied on, without the use of sterilizing agents, and the sooner engineers make use of them, or design others to perform first-class work, the sooner will doubtful practice be removed.

Any of the types of filters described can be made to give such results if they are not hampered by considerations of cutting down cost.

The greatest evil is facing modern times in resorting to practice of whose effect we are ignorant, when natural means of treatment will give a margin of certain safety.

As has been pointed out, water may be the only source of organisms necessary for the proper performance of bio-chemical functions in the body. The removal of these germs would make the functions of the body entirely chemical, a position which might lead to the destruction of the body's tissues until it could be adjusted to the new order of things.

Chlorination, sterilization by ozone, distillation, and other means of securing final sterilization, are being carried on at the present time in entire ignorance of all the uses of the body of those very properties which are being destroyed.

The whole tendency of modern therapeuthy is towards prevention of disease by sanitation, or the use of antitoxines, or its retardation by small doses of reactionary drugs to stay the progress of the disease, until the recuperative powers can reassert themselves.

Why, then, should these very recuperative powers be weakened by extreme preventive measures?

A census of operative cases, such as appendicitis, in cities using chlorination, or other sterilization treatment, might produce interesting results. In cases of strangers succumbing to disease when in strange cities, a census might also be taken and consideration given as to whether their resistive powers had not been weakened by the water treatment in their home town.

Would it not be wise to withhold drastic treatment until the need for it has been scientifically demonstrated, and its effect on the body placed beyond doubt

The importance of this point is too great to be neglected and affords excuse for the somewhat lengthy discussion of bacterial life at the beginning of this paper.

PROGRAMME OF AMERICAN GOOD ROADS CONGRESS, PHILADELPHIA.

Plans for the Fourth American Good Roads Congress, to be held under the auspices of the American Road Builders' Association in the First Regiment Armory, Philadelphia, Pa., are being worked out in detail by the Convention Committee and officials having the matter in charge.

The following outline of programme shows the subjects to be discussed at this convention:—

Subject A—Organization:

1. Highway Officials—Their Duties and Powers.

2. Division of Expense, of Responsibility and of Authority Between the Various Municipal and Other Units Participating in a Road or Street Improvement.

3. The Relation to Each Other of the Contractor, the Chief Engineer, the Resident Engineer and the Inspector.

4. Details of Arrangements for the Use of Convict Labor.

Subject B.—Construction:

1. The Proper Determination of the Amount of Re-Alignment and of Grading to be Done.

2. The Factors Governing a Proper Selection of a Road or Street Pavement or Surfacing.

3. Materials and Methods Suitable for Road Surfaces.

4. Unit Price vs. Lump Sum Contracts.

5. Plant Equipment.

6. Preliminary Traffic Census.

7. Efficiency and Economy of Using One Size Crusher Run Stone Bituminous Concrete Pavements as a Substitute for Bituminous Pavements Constructed by Penetration Methods.

8. Dirt Roads.

Subject C—Maintenance:

1. Sub-organization for Securing Efficient Maintenance.

2. General Methods of Repairs and Renewals.

3. Methods of Dust Prevention.

4. Maintenance of Different Road Surfaces.

The general plan of providing for discussion of subjects, rather than long papers, which has been so successful in the past, will be adopted at this meeting. The speakers are being selected with reference to their fitness to discuss the various questions, and announcement of these assignments will shortly be made. The list of speakers will include the men who are recognized as the leading authorities in the United States and Canada.

In connection with the Congress and Convention, there will, as usual, be held an exhibition of road machinery, materials and appliances. This exhibition will be known as the Fifth Annual Good Roads Exhibition, and will include everything that enters into the construction, repair and maintenance of roads and pavements. This exhibition will also be held in the First Regiment Armory.

This association was the first to inaugurate these exhibitions and they have uniformly been successful, each having been larger and more complete than the one previous.

TUNNELING.

By Robert B. Sinclair,
Assistant Engineer, Jennings and Ross, Toronto.

TUNNELING is by no means a modern feat of engineering. In the early times the ancients resorted to it as a means of obtaining passage for their thoroughfares under their rivers, and also as a means toward drainage; but on the whole the operation was rather a crude piece of manipulating. That science has made great strides since those days, the instruments by which the great engineering obstacles can now be very quickly overcome, is but one of many illustrations. In the following paragraphs a few of the methods that are being followed in tunneling are briefly described.

Preliminary Surveys.—When it has been decided to tunnel in order to obtain a passage-way for railroads, electricity, waterpower, or whatever the case in question may be, we must have some idea of the obstacles which are to be overcome, such as the amount of material to be excavated; the nature of the material, whether loose gravel, rock or quick-sand, and also an idea of the surrounding country, as regards the necessary depth to rock, etc. A great many other data, which will be barely mentioned, must be gathered, and in order to obtain this a geological survey party is sent on to the field of operation. The information is obtained from the geologist's knowledge of the rock formation, and also from diamond drill borings, which are taken at intervals in the vicinity. Upon the rock formation depends the nature of the blasting, as it will be more efficient if the rock is attached perpendicularly to the stratification.

Generally speaking, a horizontal strata is very much weaker than a vertical strata, and, as a result, it needs heavier supports in the shape of tunnel lining, bracing, etc. Upon the geologist's report the character of the construction is to be based.

Centre Line of Tunnel.—Tunnels are divided into two classes—curvilinear and rectilinear. We will not follow the detail of curvilinear tunneling here, but will touch upon the rectilinear, as it affords a better discussion for a general treatise.

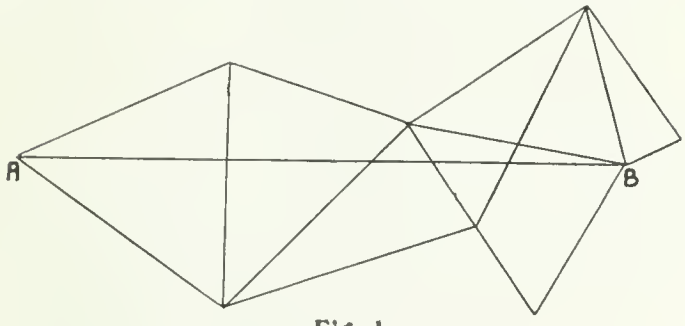

Fig. 1.

The centre line of a rectilinear tunnel is obtained by means of a triangulation survey. This must be carried on with the utmost accuracy. The angles and chainages must be read a number of times, and the results obtained by the method of least squares.

The triangulation method is illustrated very well by the above diagram shown in Fig. 1. It can be seen that the utmost accuracy can be obtained in this method of procedure. The line is staked out preliminary to the beginning of construction.

It might be said here that nearly all tunnels of any length are not worked completely from end to end, but have intermediate shafts by which the tunneling is carried on to much greater advantage.

The method of obtaining the line underground is illustrated in Fig. 2.

The depth is calculated from the profile of the tunnel. A-B is on the offset tunnel line. The plumb-bobs C and D give the direction of the line beneath the surface. A small tunnel is run to the main tunnel in question, giving a means by which the tunneling can be operated at this point.

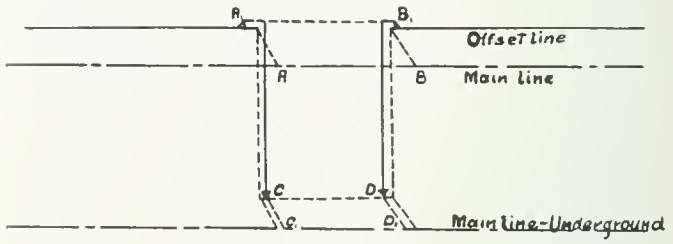

Fig. 2.

Different Methods of Tunneling.—The different methods of tunneling are in no way a small study by themselves. If we ponder for one moment over the subject we shall see the difficulty of preventing "cave-in" while the tunnel is under construction. This difficulty is off-set in a number of ways. Engineers of different nations have ways and means of their own, and from them are developed the methods by which every kind and condition of material may be encountered and successfully overcome.

We will see by the following how cleverly the methods are developed, and yet, after all, common sense is the one fundamental of them all. In fact, the basis of engineering is common sense and surveying.

Rock Tunnels.—Rock tunnels are carried through by the drift and the heading methods. The drift method is shown in the design by Fig. 3.

The parts 1, 2 and 3 are excavated, leaving supports 4 and 5, upon which is built the arch of the tunnel. At intervals along the side transverse cuts are made and filled in with the masonry. These support the arch after 4 and 5 have been cut away.

By Headings.—The more common method of rock tunneling is by the heading method.

Section 1 in the diagram (Fig. 4) is drilled through perhaps 200 feet to 300 feet in advance. Parts 2 are drilled into until finally we arrive at the point of constructing the arch structure. It is built up on the unexcavated rock below and is supported by 4 and 5, while fissure 3 is opened up. Parts 4 and 5 come next, and the lining is then inserted.

It might be interesting to mention the fact that rock tunnels do not require the heavy lining that is used in ground tunnels. This is very well understood on account of the fact that the rock walls are self-supporting, except where some crack or fissure allows the side to break off. These cracks and weakenings are caused by heavy blasting and also by the rock structure. If the strata is perpendicular to the side of the tunnel it will have greater tendency to cave-in than if the strata is parallel to the side. The St. Gothard tunnel is a very good example of the heading method of excavation. The tunnel was constructed in 1872-82, and is one of the longest tunnels at

the present time. It connects France and Italy under the Alps Mountains, and is 9¼ miles in length.

Passing from rock to earth formation in connection with tunneling, the earth formation is much more difficult to successfully tunnel. Although it might not appear so on first consideration, the blasting and removing of rock is a very simple operation in comparison to the removing of soft material, in the face of a cave-in, quick-sand and a great many other obstacles, which cannot be gone into here.

A Good Method of Blasting.—The explosives used in the blasting operation consist principally of gun-powder, nitroglycerine and dynamite. The methods used are various, but one which is used a great deal and which seems most efficient is the American centre cut method.

In this method seven or eight holes are bored in the facing in the form of a polygon, the holes tending to terminate at the point. The holes are charged and fired, extricating the conical, or pyramidal structure. Another circle of holes is forced in a cylindrical form round about this opening. These are charged and fired, and a cylindrical shaped fissure is opened. In this way the blasting operation is carried on until the opening is brought to the required size and shape.
